Jamaica. Mr. Holgate will go to Kingston, Jamaica, about the first of February, where he will superintend the erection of about 25 miles of railway, which will probably be extended later on. Henry Holgate was born in Milton, Ont., in 1863, and served his apprenticeship with the Northern Railway of Canada. He became chief engineer of the combined Northern and North-Western Railways, which were merged into the Grand Trunk in Feb., 1888. He continued as chief engineer of this division under the Grand Trunk till 1892, when he took charge of the Central Bridge and Engineering Co., of Peterboro, as engineer for a year, during which the steel work of the new Union Station at Toronto was constructed. He came to Montreal in June, 1894, as engineer for the Royal Electric Co., and built and equipped the new factory. The directors of the Royal Electric Co. being interested in the Montreal Park and Island Railway, he was transferred to the latter company in June, 1895, where he remained in charge of operation and construction to the present time. We hope the readers of THE CANADIAN ENGINEER may hear from Mr. Holgate in his new field of operations.

ELEVATORS: ELECTRIC VS. HYDRAULIC.

Editor CANADIAN ENGINEER :

SIR,—I trust you will allow me to reply to the discussion by Mr. Philip, in the December issue of THE CANADIAN ENGINEER, of the comparative merits of electric and hydraulic elevators for the city hall of Toronto. It would seem probable that Mr. Phillip has more knowledge of the operation of hydraulic than he has of electric elevators. The comparisons and statements made by him are open to serious question, and as his opinions may have weight with the readers of your valuable paper, I will state briefly my reasons for disagreeing with some of his conclusions. His divisions of first cost, safety, reliability, economy and cost of maintenance will be followed.

Cost.—The first cost of the electric elevator plant was $30,000, and the cost of an extra high speed engine, dynamo, incidental apparatus and piping to run such elevator would be less than $5 000—total cost of $35,000, or $10,500 less than the bid of the lowest hydraulic elevator company, If the lighting engines were merely enlarged to meet the wants of the elevators, the difference will be still larger.

Safety.—Again I must take exception to Mr. Philip's statements. The electric elevator is safer than the hydraulic; in addition to the mechanical safety devices of the latter, there are independent electric safety appliances, which not only prevent actual drop, but prohibit unsafe increase in speed. Of still greater importance is the condition that the tendency of the electric machine is toward safety, that is, leaks, short circuits or trouble of any kind tends to remove power and prevent motion, while in the hydraulic elevator the tendency is exactly opposite, a leak or a break meaning movement in one direction or the other. This is clearly shown in the familiar "creeping" of the hydraulic elevator due to air in the cylinders or leaks of one kind or another; yearly there are several deaths due to this cause.

Neither is there an elaborate "cycle of changes" in applying power. Current is applied to a solenoid, causing a switch to close the motor circuit, and gradually cut out resistance to the current flow. To stop the car, the auxiliary current is cut off by releasing a push button and all switches open; the car then stops, due to the nature of the worm gear, and in some cases to the use of an auxiliary brake thrown on mechanically, or by closing the motor circuit on itself, causing the car to do work and slow up. Hence there is no power "used to stop the car as well as to start and run it."

Reliability.—The machinery of an electric elevator does not appear complicated—it is in use in hundreds of New York buildings and receives the least possible care and attention; it is practically the simplest method of hoisting a weight, similar in some respects to the hod hoists, and consists of a drum around which the hoisting and counterweight ropes wind, the drum being driven by worm gear and electric motor. The comparative wear and tear of the two types is yet to be determined. So far electric elevators have not shown signs of wearing out, but taking the generating machinery into consideration, their life is probably less than that of hydraulic pump and cylinder. The difference is not of great moment.

Economy.—Here I must absolutely contradict Mr. Philip. His contention that a plant of underbalanced hydraulic elevators is more economical than a plant of overbalanced electric elevators is totally at variance with both theory and practice. He states that the pump does an average amount of work continually. This is not quite true, as the size of the pressure tank for such a condition must be abnormal, but for purposes of discussion it may be taken as a fact. But even so, the "average" work done is not the "average" work of the electric elevator plant. In the first case, as the work is the same irrespective of the load lifted, it is the average of the maximum capacities of the elevators plus one-third of the weight of the unloaded cars. In the second case the work done is merely that due to lifting the difference between the actual live load and the average load, and this is reduced by the return of current to the source of supply by the descending elevators. Figures taken from about twenty elevator plants of this type in New York city show from 1.7 to 2.5 kilowatt hours per car mile, with speeds varying from 250 to 400 feet per minute, capacities from 1,500 to 3,000 pounds and cars from 20 to 30 square feet area. The coal per kilowatt hour in one of these buildings was from 4 pounds in summer to 5⅓ pounds in winter, using simple Corliss engines direct connected to electric generators, while another building with high speed simple engines and long lines of piping required from 8 to 9 pounds. The car miles per day varied from 10 to 22, depending on the speed. Taking an average of 16 miles and 2.1-k.w. hours per car mile, the coal per car per day, in an electric plant where light is also supplied, is from 135 to 300 pounds, depending on the type of engine and heating conditions. Two hydraulic elevators operated by compound pumps, under the best conditions, in a fire insurance building in New York, use 1,000 pounds of coal per day, while with a simple pump in the same building they used 1,500 or from 500 to 750 pounds per car per day. Where expensive high duty pumps are employed the test of the American Tract Society elevators by Charles E. Emery, Ph.D., shows the coal per mile to be over 28.8 pounds, or 461 pounds for 16 car miles under test conditions. These cars were built for high speed and are not of course to be compared with the elevators in question, but it is safe to say that electric overbalanced worm-gear elevators will not and do not use over three-fifths the coal per car mile in ordinary conditions, that would be and is required for hydraulic operation, and the proportion will generally be less.

It is not necessary to have a plant of rated capacity equal to that of all the elevator motors, though Mr Philip appears so to believe. Its rated capacity need not be more than is required for starting two elevators and running the other two (if there are four installed), as all engines and generators are built now-a-days with an excess momentary

capacity of from 50 to 100 per cent. Nor is there any short circuit of the motor on starting—as in all types of electric elevators variable resistance is inserted at starting between the generator and motor. I am sorry not to be able to coincide in my views as to storage batteries with those expressed by Mr. Philip. They seem to me to have decidedly passed the experimental stage and have become a recognized part of the modern building plant installation where economy is obtainable by their use. Whether they would be advisable for the city hall is quite another question.

It may be of interest also to state that the Edison Illuminating Company of New York does not consider "electric elevators a curse to a lighting station." They have installed one in their building as an object lesson and advocate their use as much as possible.

In conclusion I am glad to be able to agree with Mr. Philip as to the advisability of installing an isolated plant. In general, with a building as large as the city hall, a private plant will prove highly economical provided it is managed as it would be by a private corporation.

Very truly yours,

PERCIVAL ROBERT MOSES,
Consulting Electrical Engineer.

35 Nassau St., New York,
December 27th, 1897.

STEEL RAIL HIGHWAY PROPOSED BY THE U. S. DEPARTMENT OF AGRICULTURE.

Complete designs for wagon roads, with steel trackways, have been prepared by Gen. Roy Stone, Director Office of Road Inquiry, U. S. Department of Agriculture. As many of our readers know says the *Engineering News*, the Agricultural Department has given much attention to the subject of good roads and has organized the office of Road Inquiry to foster highway improvement and experiment with different systems of country road construction. Through the efforts of this office a model macadam road has been built at New Brunswick, N.J., and a combination macadam and dirt road, 7,000 feet long, at Geneva, N.Y. The road at Geneva has a centre of macadam 8 feet wide, with rolled dirt roadways on each side. These samples of road construction are designed to be object lessons in the economy of good material and construction for country roads.

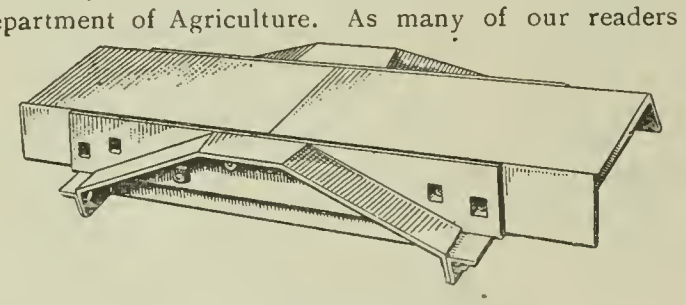

FIG. 2.—PERSPECTIVE VIEW OF RAIL JOINT FOR STEEL RAIL HIGHWAY.

The possible advantages of combining a steel trackway for wagons with the broken stone centre, has led the Office of Road Inquiry to investigate the subject with the idea of building an experimental road of this kind. This study has resulted in the design of the steel rail highway which is illustrated in the accompanying cuts. Fig. 1 is a cross-section of the completed road, showing the arrangement of the steel rails and stone filling, and the nature of the drainage system. Fig. 2 is a perspective view of the rail joints, and Fig. 3 is a transverse section of the same joint.

FIG. 1.—CROSS-SECTION OF STEEL RAIL HIGHWAY, DESIGNED BY THE OFFICE OF ROAD INQUIRY, U. S. DEPARTMENT OF AGRICULTURE.

As will be seen from the illustrations, the general idea is to lay two parallel lines of steel rails, supported by a broken stone filling. These rails have an inverted trough section, the top of which forms the track for the wheel, and is 8 inches wide, with a slightly raised bend on the inside edge to guide the wheel. The thickness of the top of the section which forms the track is about 7-16 inch, and the total weight of the steel and connections is about 100 tons per mile of single track. The rails will be connected transversely at intervals to prevent spreading, but there will be no cross ties, the broken stone ballast alone supporting the rail.

The construction at the joints is shown by Figs. 2 and 3. An inverted trough, Section A, forms the basis of the joint support. Over this trough are slipped the two ends of the track rails, B B, which meet in a butt-joint at the centre. To each side of the track rails are attached the remounting devices, C C, connected at the ends by the transverse angles, D D. These three principal parts which make up the joint are firmly bolted together, as shown by the drawings. The object of the remounting device is, of course, to enable heavy wagons, which have left the rails, to be easily returned to the track by mounting the inclined shoulder at the rail joints.

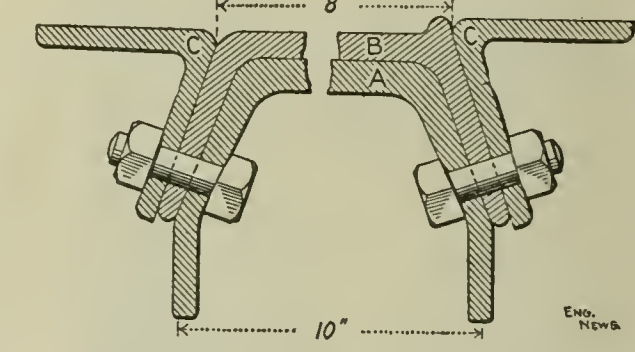

FIG. 3.—TRANSVERSE SECTION OF RAIL JOINT FOR STEEL RAIL HIGHWAY.

Arrangements have been made with the Cambria Iron Co., of Johnstown, Pa., to roll these track rails, the arrangement to go into effect as soon as definite orders for an aggregate of one mile of road are obtained. It is estimated that the cost of rails and joints for one mile of road in the United States will be $3,500. As indicating the possible utility of steel rail highways, Mr. Stone has obtained information regarding two previous experiments with steel rails on wagon roads, and has furnished us copies of the letters from the builders, which describe the construction and operation. The first letter is from F. Melber, engineer and contractor, Standard Building, Pittsburg, Pa., and is, in substance, as follows:

"My road has been in position for about a month, and, among other interesting things, I watched the temperature of the steel when exposed to the hot afternoon sun. Every steel worker knows that steel bars lying in the yard of a bridge works, for instance, will get so warm in a few minutes that the men cannot hold them in their hands. I find that my steel stringers remain cooler than the adjacent broken stone. This, I think, is a remarkable as well as an important fact, and it goes to show that there takes place an interchange of the temperature between the inner substances and the steel, and that in this class of steel highways we do not need to provide for expansion. Altogether, I find the steel road to verify all I have said about it, even as to cost, and with regard to traction advantages I am now able to give figures. I have made twenty trials, using a gauged spring balance, and find that the average force needed to pull the iron wagon, weighing 1,550 lbs., with a 16-foot wagon-bed, is 2.5 lbs., which, reduced to a load of 2,000 lbs., means a traction force of 3 23 lbs. per ton."

The second letter is from Abel Bliss, of New Lennox, Ill., and is as follows:

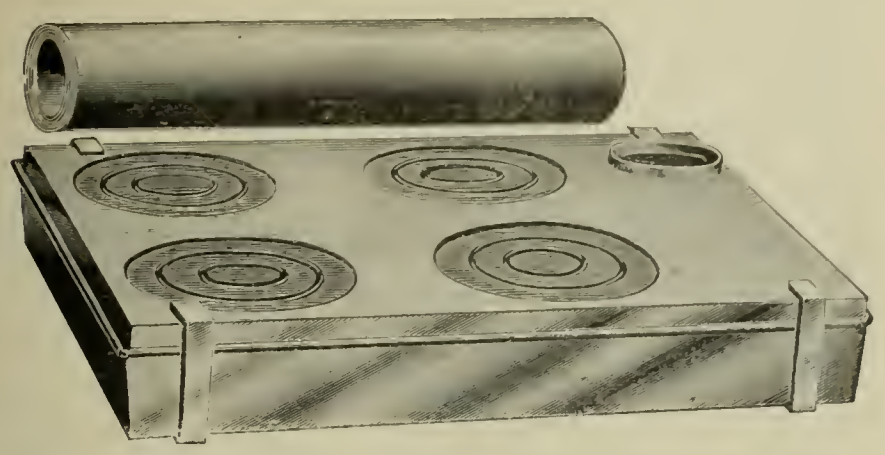
"I take the liberty of giving you my experience with a steel roadway which I placed in the public highway near my home, four miles east of Jolliet, Ill. It was put down April 2, 1896, on a dirt road of typical Illinois soil, and consisted of a steel rail ¼ in. thick and 8 ins. wide, with a flange 3 ins. wide turned down on either side and a ¾-in. flange turned up on the outer edge to keep the wheels on the rails These rails were let into the ground so that the flat part rested on the earth, and were fastened together at the ends by fish plates, which are so constructed as to run the wheels onto the rails after passing a team. The earth between the rails was removed to a depth of four inches, and the space filled with gravel for a tread for the horses. These roads have been tested with all kinds of loads, including traction engines, and have retained their position very well. While the mud made the roads almost impassable here during the winter, a team could have trotted on this roadway any day with a two-ton load. About 50 tons of steel per mile will be required, having the rails ¼ in. thick, which I think is ample."

These experiments are of much interest to Canadians, especially in the neighborhood of large cities where the vehicle traffic is heavy. The added profits which every farmer would make on his produce with such roads as this would be a material factor in the development of the country.

INCORPORATION has been granted to H. S. Griffin, M.D., T. J. Stewart, W. Trusdale, Hamilton, Ont.; J. Dickenson, Glanford, and W. M. German, Welland, Ont., as the Odorless Crematory Closet and General Heating Company of Hamilton, Limited, to manufacture, sell and deal in odorless crematory closets and heating furnaces. Capital, $24,000.

TESLIN STOVES.

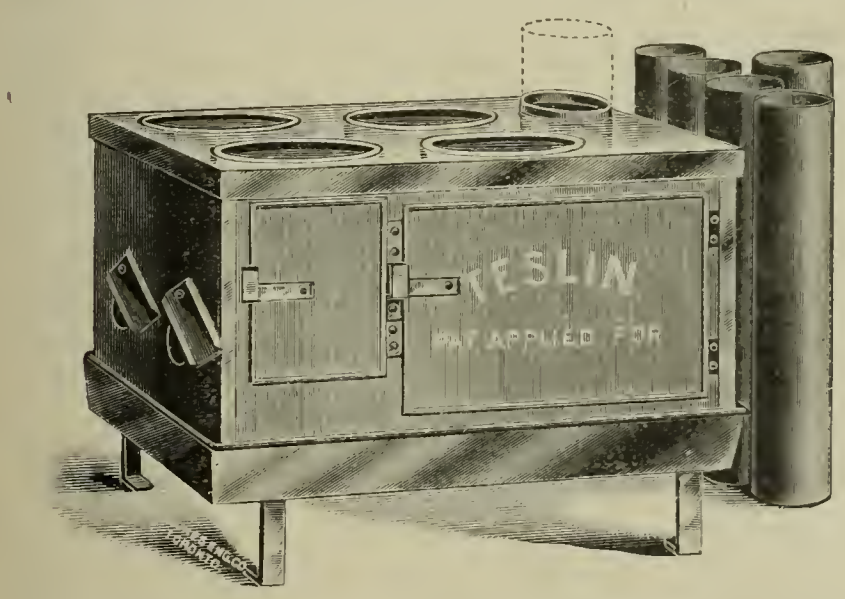
The peculiar conditions of life in the golden north are rapidly bringing into being a number of entirely new appearances to fill new wants, and also old appliances so changed as to be hardly recognizable. The peaceful blanket of our more genial climate has become the fur-lined sleeping bag of the Klondyke, and the kitchen range of the south east built into the chimney and occupying yards of space has become in the far North-West the Teslin stove, which when closed up for car-



STOVE FOLDED UP.

riage occupies a space of 28x22x4 inches, and weighs with 9 feet of pipe only 53 lbs. The following are the dimensions of the Teslin stove when set up:—Size of top, 28x22 inches; height, 13 inches: size of oven, 22x14x9 inches; size of fire-box, 22x9x13 inches; size of fire door, 6x8 inches; size of pipe collar, 5 inches; weight with pipe, 53 pounds.

The method of setting up the stove is simplicity itself. The shipping bands become feet, and by a few easy movements, much as a



cardboard box is opened for use, this stove is set up. An illustrated card giving full instruction of the process of setting up the stove is supplied to purchasers.

This stove has direct as well as indirect draft, and the arrangement of flues direct the heat around the oven for baking as in a high-priced cook stove. The simple construction of the stove renders it perfectly rigid when put together, and the heavy angled corners assist in preventing the stove from warping.

Has four 8¼ inch pot holes on top.

Five lengths of telescopic pipe (supplied with each stove) wil extend to 9½ feet. Also supplied with thimble for tent through which pipe passes.

These stoves are being placed on the market by the McClary Mfg. Co., London, Ont.

The McClary Mfg. Co. is making a specially praiseworthy effort to meet the demands of trade created by the opening up of the northern country, and is issuing a special catalogue giving details o goods adapted to the gold country.

FIRES OF THE MONTH.

Nov. 4th—Macpherson & Co.'s Foundry, Fingal, Ont. Well insured.——Nov. 5th—Sydney Cheese Factory, J. R. Bower, Belleville, Ont., manager. Loss on building, $1,000. To be rebuilt at once.——Nov. 11th.—J. L Pollock's saw mill and electric light plant, Drayton, Ont.——Dec. 2nd.—American Tire Co., King Street, Toronto, Loss, $6,000.——Dec. 17th.—Tate & Bateson's planing mill, Bracebridge, Ont. Loss, $2,000; no insurance.——Dec. 31st.—Kingston General Hospital, Walker's wing. Damage, $10,000.——Jan. 5th.—Ottawa University, east wing. Loss, $50,000.——George W. Reed & Sons, manufacturers of sheet iron and roofing materials, Montreal, three store sheds. Loss, $12,000; cause unknown.——Lancaster Machine Works, Lancaster, Ont., shops partly destroyed on 1st January Loss about $1,000, no insurance; will rebuild at once.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the metal imports from Great Britain during November, 1896, 1897, and the eleven months to November, 1896-1897.

	Month of Nov.,		Eleven months ending Nov.,	
	1896	1897.	1896	1897.
Hardware and cutlery	£5,734	£5,224	£58,897	£63,717
Pig iron	1,732	2 724	27,936	[illegible]
Bar, etc.	1,190	751	15,239	[illegible]
Railroad	2,525	11	174,434	[illegible]
Hoops, sheets, etc.	4,044	6,562	46,721	[illegible]
Galvanized sheets	7,435	3,620	54,407	52,606
Tin plates	42,731	54 450	153,220	217,421
Cast, wrought, etc., iron	2,912	3,090	47,861	31,979
Old (for re-manufacture)	160	1,201	15,756	7,654
Steel	5,679	4,455	85,548	51,956
Lead	3,076	3,451	16,355	27,401
Tin, unwrought	6,631	2,386	20,208	17,369
Cement	1,735	1,306	32,766	19,797

Mining Matters.

THE mineral exports from Nelson, B.C., during 1897, amounted to 53,971 tons, valued at $7,891,329.

A PLAN is proposed in Kingston, Ont., to open up the lead mines in Frontenac county and have the ore reduced in Kingston.

KOLIN, the clay from which porcelain is made, is said to have been discovered not far from Halifax, N.S., and of the finest quality.

D. A. JONES, Beeton, Ont., reports the find of an extensive area of quartz, rivaling the famous Hammond reef near Wahnapitae, Ont.

THE Le Roi mine has paid its regular monthly dividend of $50,000 in spite of the expense incurred in building the Northport smelter.

ASBESTOS, comparatively a new mining town near Danville, Que., claims to have a population of 1,500, and is seeking incorporation as a village.

A TRACT of sand carrying alluvial gold is reported to have been discovered recently about ten miles from Chatham, Ont., in Raleigh township.

A FIND of platinum is said to have been made about two miles in the interior from Stevenville, St. George's Bay, Newfoundland, by Garret Dalton.

THE galena found on lot 9, con. 4, Calumet Island, Que, has assayed as high as $60 per ton in silver, with traces of gold. The outcrop is about 18 x 40.

THE Ontario Government diamond drill is working on a gold property known as "J. C., 66," a few miles east of Rat Portage, owned by N. B. Eagen, Toronto.

C. RIORDAN and J. R. Barber, Toronto, are promoting a stage line from Edmonton to Dawson, and the construction of a telegraph line. They will organize a company, it is said.

THE black gold-bearing sand which is attracting so much attention in the Saskatchewan is also found in many of the streams in British Columbia, notably in the Kootenay.

THE B.C. mine at Greenwood, B.C., has ordered a complete development plant from the Jenckes Machine Co. Sherbrooke, and work will be pushed on this property this winter.

W. AUSTIN, Cardiff township, Haliburton county, Ontario, reports a find of ore including gold and copper on his farm. Tests are said to show $16.80 in gold and $24 in copper to the ton.

THE New England Gas Company has contracted with the Dominion Coal Company for 100,000 tons of coal to be delivered annually in Boston, with the option of taking 1,500,000 tons.

THE Le Roi Mines, Rossland, B.C., are extending their pumping system, and have placed an order through the Rossland branch of the Jenckes Machine Co., Sherbrooke, Que., for a large size special Knowles Sinking Pump.

THE Virginia Mines, at Rossland, B.C., have passed the preliminary stage and will now enter the list of shippers. An order for a large hoisting plant with boilers has been placed with the Rossland branch of the Jenckes Machine Co., Sherbrooke, and is now on the way from the East.

At Phillip's Arm, B.C., the British Columbia Gold Fields Company has established a trading post.

Jas. Conmee, M.L.A., predicts that in a year and a half there will be 1,000 stamps at work in the Rat Portage district of Ontario.

W. A. Hungerford is going to smelt the gold-bearing ores of Hastings County, it is said, on a small scale near Millbridge, Ont.

Extensive deposits of bituminous coal have been discovered at Dominion City, thirty miles from Winnipeg, at a depth of a hundred feet.

A. E. Hogue, representing a large English company, has recently examined the pay bars on the Saskatchewan River, with a view to putting in gold dredging machinery on a large scale in the spring.

The final clean-up of the Cariboo Hydraulic Mining Co. was made on Nov. 11th. The total yield of the season was $139,000. The water supply was only about half that of last year and the output was very much restricted thereby.

The Fern mines, Hall Siding, Rossland district, B.C., are lighting up the mill and yards, as well as the tunnel of the mine, by electricity, and have placed the order for machinery and apparatus with the Royal Electric Company, Montreal.

A seam of coal found near Sydney, N.S., by E. T. Mosely, will largely increase the coal area of Cape Breton. The seam is known as the Mullins seam, and is six and a half feet wide. It is 14 miles from Sydney, on the Cow Bay road.

The West Vancouver Coal Company, in which H. C. Haliday and other San Francisco capitalists are interested, will, it is said, develop their coal mines at the north end of Vancouver Island and establish a coaling station for Alaska steamers.

A nickel smelter is proposed in Toronto, to cost $500,000. If an export duty were placed on nickel matte, it is thought that capital could be secured to carry on the smelting in Ontario. R. J. Tough is promoting the enterprise in Toronto.

The Ontario Lithographic Stone and Mining Company, Limited, has received an Ontario charter; $250,000 capital. It is to be composed of A. L. Davis, H. S. Macdonald, J. W. Gray, R. M. Dennistoun and F. J. Jameson, Peterboro, Ont.

A. Drolet, manager of the Saskatchewan Gold and Platinum Mining and Dredging Company, has fitted up the Benoit & McKay dredge at Edmonton, N.W.T., at great expense, and it will be used in gold dredging and washing next season.

In the main shaft of the Foley mine, Lake of theWoods district, Ont., which is now being pushed towards the 400 foot level, there is 6½ feet of fine ore in the winze between the 200 and 300 foot levels, and four feet in the drift at the 300 foot level.

The Jenckes Machine Co., Sherbrooke, are furnishing the Canadian Rand Drill Co., Halifax branch, with one of their 20-inch Crocker Special Turbines, to be used in connection with the extensive hoisting plant being installed by the Drill Co. at the Torquay mines.

A. Mackenzie, Montreal, reports that gold is being washed successfully from the Saskatchewan River for 250 miles, the men averaging $1.50 to $4 per day each. About fifty per cent. of the gold is lost owing to its fineness. The bars may be worked over year after year, it is said, and more gold will always be found.

The officials of the Hammond Reef Gold Mining Company have announced the result of their first clean-up. From 259 tons of ore run through the ten-stamp mill five pounds (avoirdupois) of gold were caught on the plates. This is about $5 per ton, and with such a value the Hammond reef is a gigantic proposition, for the deposit is from 50 to 100 feet wide, and the ore can be mined and carried to the stock pile at less than 50 cents per ton.

The bond on the Lynn Creek properties, close to Vancouver, B.C, has been thrown up. The ore is found to contain too much zinc to be profitably worked. This is not the case, however, with copper-gold properties on Texada Island and Phillip's Arm, situated several miles north of Vancouver. Mining companies operating in these sections have shipped thousands of tons of ore as far away as Swansea and with fair results.

It is stated that the New England Gas and Coke Co. will produce from the Nova Scotia coal coke, illuminating and fuel gas, tar and ammonium sulphate—70 per cent. of coke, 10,000 feet of gas, 12½ gallons of tar and 28 pounds of ammonium sulphate to the ton of coal. One half the gas will be used in coking the coal, the rest will be available for the market and may be sold under the pipe line charter at not exceeding 65 cents per 1,000 feet.

Major Hepman, of the Fourth Royal Fusiliers, and Capt. Alleyne, of the Twelfth Lancers, have started from Edmonton for the Klondyke. The party consists of 14 men, including two doctors, besides the packers, drivers, guides, etc. They have 120 horses, a number of dog teams, etc., and expect to put in a number of tons of supplies into Dawson. After reaching Dawson they will survey the country east of the Yukon. Capt. Alleyne is also Reuter's correspondent.

The property of the old Frontenac Lead Mining Co., of Loughboro township, near Kingston, has been bought by some Toronto men who propose to organize and re-open the works under the name of the Frontenac Lead Mining and Smelting Syndicate. The late George Spotswood always contended that, under good management, which the old company never had, this lead mine would pay well, and the new company proposes to put this to the test by putting in a drift below the present workings.

The construction of the new reverberatory and calcining furnaces at the Hall Mines' smelter is being pushed, and it is expected that they will be completed in about two months. The large blast furnace made a run recently which broke the record, turning out 26 tons of matte in 24 hours. Everything is working smoothly and the ore treated continues to be of a very high quality. The management is smelting lead ores from the Slocan in the old 130-ton furnace, which has been converted into a lead furnace.

The Canadian Copper Company, an Ohio concern, and the Anglo-American Iron Company, which control the output of the nickel and copper mines around Sudbury, have special charters domiciling them in Canada on certain conditions, one of which was the establishment of smelting works for the reduction of the ores. It is claimed that in breach of that they have taken their ore to the United States and had it smelted there, and that they have spent in wages and railway freights about $1,250,000 a year in this way outside of Canada. B. B. Osler, Q.C., of Toronto has filed in the Department of Justice, at Ottawa, a petition to the Attorney-General of Canada for leave to bring an action against these companies to revoke their charters.

The Dominion Coal Co., in reply to the criticism regarding the closing of its two collieries at Port Morien and Victoria, states that a new shaft will be opened in a more central part of the coal producing district of Cape Breton. It is stated that the new shaft and equipment will cost $250,000, and two new washing plants will be erected at a cost of $50,000 each. Later on it is intended to build a pocket at Louisburg large enough to hold a ship's cargo of 6,000 tons, with apparatus enabling this quantity to be discharged into a steamer in six hours. For this purpose a new pier will be erected at Louisburg, the outlay at this port being about $250,000. Near Sydney the company is now building a pier to cost $50,000. Altogether the company asserts that it will spend $700,000 in the next two years.

The shipments of ore from Kaslo, B.C., are an indication of the value of the Sandon silver mines. During the month of October, the shipments amounted to 8,450,000 pounds, valued at nearly $400,000. Of this 2,784,110 pounds were lead, and 397,977 ounces silver. The record for the same month in 1895 gave 735,000 pounds of ore, and for 1896 the figures were 1,286,993. The shippers of ore in the Slocan district number over 40, and the mines that are paying dividends number 25. The records show 14 shipping mines for 1895, 39 for 1896 and 53 for 1897, though some of the shippers are not shipping regularly. Returns of ore shipped from the Slocan and sworth mining district, taken from the custom house clearances for the nine months ending September 30th, 1897, show 47,435,000 pounds, valued at $1,853,000, as compared with 23,344,000 pounds, valued at $1,114,000, for the whole twelve months of 1896.

The Calumet galena mines, though owned by men in the neighborhood, is now being worked by a Belgian. The product is a conglomerate of lead and zinc ore containing from seven to twelve per cent. of silver; but about the total wealth of the mine it is at present impossible to form an opinion. The property on Chats Island is that in which Jas. Robertson, of Montreal, is interested. There is an immense deposit of pure galena without any admixture of zinc. It is easily obtained and requires but a small outlay of capital. A recent find has given the proprietors a new impulse, and it is very probable that the mine will be opened up at an early date. Mr. Tough, a well-known owner of mining property in the Sudbury district, also possesses a mine on this same island, containing a deposit of much the same character as that in the aforementioned mine. The extent of this deposit cannot be known till next spring, when the snow has disappeared. The operation of extracting the valuable metal from this ore has been somewhat difficult hitherto, but a new method has recently been discovered in Germany, which will be adopted in the cases of these mines.

A. J. G. Swinney, manager of the Canadian Gold Fields, Limited, Deloro, Ont., told the Toronto *World* recently, that the syndicate has already expended $500,000 in securing control of several square miles of territory, in opening up the same, sinking shafts, installing machinery, etc. With this as a beginning, the company will not cease their outlay

until the mines have attained a producing capacity of $5,000 or $6,000 per day. The underground work done on the property at present consists of two shafts, located a mile or so east of the reduction plant at Marmora Station, on the Central Ontario Railway, but four additional shafts are forthwith to be sunk—two near the old shafts, and the other two a mile to the north and a mile to the south thereof respectively. In order to carry on this work expeditiously, Mr. Swinney has arranged for the immediate installation of a twenty-drill air compressor. And when, with this extensive mining plant, a big ore reserve has been obtained, the capacity of the bromo-cyanogen mill will be increased, so that it will treat 400 tons per diem. Mr. Swinney says that the mispickel averages $15 per ton in gold, and that the new process saves 85 per cent., or over $12 of this. This means, as stated above, that the enlarged mill should turn out between $5,000 and $6,000 in bullion each day. It is also learned that the same money that is invested at Deloro is behind the re-opening of the Belmont gold mines, located nine miles to the northwest of Marmora Village, and formerly owned by A. W. Carscallen, M.P. The Belmont ore is concentrating, and a stamp mill is being erected upon the property.

Electric Flashes.

WALTER MCFARLANE is putting the electric light into his factory at St. Mary's, Ont.

THE Carleton Place council threw out the by-law to grant a bonus to the Lanark County Electric Railway Co.

THE Canadian General Electric Company has installed an isolated plant for A. & J. Clarke, Bullocks Corners, Ont.

THE Cardinal, Ont., starch works is putting in an electric light plant of sufficient power to furnish the works and the town with light.

ENGINEER CHURCHILL, of the S.S. "Iceland," is now in charge of the electric light station, St. John's, Nfld., in place of J. Hepson, resigned.

THE Pontiac Telephone Co. is putting telephones in each of the stations along the line of the P.P.J. Railway from Quyon, Que., westwards.

THE town council of Parrsboro, N.S., has been authorized to spend $8,000 in equipping an electric light plant, to be the property of the municipality.

ST. THOMAS, ONT., has voted to guarantee $50,000 of the bonds of the new electric street railway company, and to pay the first year's interest on them.

THE Windsor Plaster Co., Windsor, N.S., is lighting its works by electricity, and has given the order for the electrical equipment to the Royal Electric Co.

THE Toronto Electric Motor Co. is now running night and day, and notwithstanding recent enlargement of the works is scarcely able to keep up with orders.

THE Dominion Paper Mills, Kingsey Falls, Que., are installing an electric lighting plant in their new mills, and have placed the contract with the Royal Electric Co.

IT is proposed to extend the Belleville, Ont., Street Railway to Trenton and Tweed, using rails sufficiently heavy to allow of the C.P.R.'s hauling freight over the line.

THE Bell Telephone Co. will shortly put up for its Quebec headquarters a new office building, on the corner of St. John and St. Angele streets, Quebec, at a cost of $15,000.

THE St. Jerome Power and Electric Light Co. has had such success in canvassing for lights that it has changed its order from 1,000 light "S.K.C." machine to one of 1,500 lights capacity.

THE St. Lawrence Power Company is applying to the Quebec Legislature for incorporation, for dealing in water, electric, steam and any other power for lighting, heating and manufacturing.

C. E. SHEDRICK. who has assumed control of the Whitney Electrical Instrument Co., Sherbrooke, Que., has on hand a stock of measuring instruments, laboratory apparatus, X-ray apparatus, etc.

THE British Columbia Iron Works Company, Vancouver, B.C., have placed an order for a 10-kilowatt, direct connected, steel frame, incandescent lighting generator with the Canadian General Electric Company.

THE expenses of the municipal electric light plant of Lachine, Que., in 1897 amounted to $3,282, the lighting being 850 electric lights and 43 arc lamps for the entire town. The receipts for the same year mounted to $3,066.

THE Canadian General Electrical Co has recently installed a 250-light plant in the premises of the Northey Manufacturing Co., Toronto.

THE Seine River, Foley and Fort Frances Railway Company, is applying for an Ontario charter to build a line from Bonheur on the C.P.R., to Sawbill Lake, Fort Frances, etc., and to dispose of surplus electricity for power and other purposes

THE Shipton Electric Co., Danville, Que., has decided to proceed with the extension of the power plant this winter, and has made a contract with the Jenckes Machine Co., Sherbrooke, for a Crocker turbine, horizontally set, with penstock and draft tube complete

THE officers of the Sherbrooke, Que., Street Railway Co. are: President and chief engineer, John W. Burke; directors, Percival W. Clements, Rutland, Vt.; Edgar Harding, Boston; Walter Blue, Wm. Morris, Sherbrooke; superintendent L. E. Whitehead, secretary, F. J. Griffith.

BOBCAYGEON, ONT., has a scheme to secure electric railway communication with Peterboro. The proposal is to build a line to Scott's mills, some twelve miles east, then south to Buckhorn, and on to Peterboro. It has been estimated that the line can be built for less than $200,000.

THE Edmonton Electric Light Co., of Edmonton, N.W.T., is improving and extending the plant. The new electrical equipment bought by them from the Royal Electric Co., consists of one 75 K.W. "S.K.C." two-phase generator, complete, with exciter and switchboard, as well as the necessary material for the other changes.

THE Canadian General Electric Company has recently closed a contract with the Bushnell Oil Company, Sarnia, for a 25-kilowatt direct connected, steel frame, incandescent lighting generator, coupled to an "Ideal" engine. This installation will embody all the latest improvements in direct connected practice, which the Bushnell Company, from its connection with the Standard Oil Company of the United States, has learned to value through their experience there.

THE turning on the power and light in connection with the new municipal electrical lighting plant, at Magog, Que., was made the occasion of a reception given by the Mayor and Councilors in the Opera House. The hall was brilliantly lighted by incandescent lamps, and the whole town turned out. Speeches were made by Mayor Bessette and other councilors and a very pleasant evening was spent. Magog is one of the first towns in the Eastern Townships to own and operate its own lighting plant. The power is obtained from the Magog River, a little below the cotton mills. The water wheel plant of the Crocker special type was furnished by the Jenckes Machine Co., Sherbrooke, Que.

THE Canadian General Electric Company is supplying a 1,000 light direct connected, incandescent lighting plant for the Gutta Percha and Rubber Manufacturing Co. This installation will be, when finished, one of the most complete in the country. The machine is of the steel frame, ventilated, armature type, direct connected to an "Ideal" engine, running at the slow speed of 250 revolutions per minute. The great saving in space, durability and high efficiency obtained by the use of these direct connected units has led to their adoption as the standard machine where it is desired to obtain the best and most economical conditions in operating an isolated incandescent lighting plant.

THE Packard Electric Company, Limited, St. Catharines, Ont., announces that it has recently imported from England a sand blast frosting machine, which it is claimed produces frosted lamps far superior to those which have been previously placed upon the market. The effect produced by frosted lamps is appreciated by everyone, but their use in the past has been exceedingly limited, both on account of the inferior class of work in this line, as well as the price charged. The company is also in a position to do any style of fancy frosting, bringing out letters, monograms and any desired design, upon lamps to be used for decorative work. The fine frosting, which this up-to-date machine produces absorbs much less of the light than any ordinary frosted lamp.

THE plant and franchise of the Temple Electric Co., Montreal, have been acquired by the Standard Light and Power Co. The Lachine Rapids Hydraulic and Land Co. have made a contract with this company to supply it with current from the Lachine Rapids and the steam plant will be sold. The Lachine Co. has also closed a contract with the Imperial Electric Co., formerly the St. Jean Baptist Electric Co., to supply it with current, replacing the present steam plant. Although the thermometer has been down below zero this winter, no difficulty has been encountered with frazil ice.

E. RUTHERFORD, electric supplies, Peterboro, Ont., has assigned to R. R. Hall.

M. S. CORNELL, Stanbridge East, Que., is planning to install a lighting plant next spring.

G. C. HINTON & Co., Victoria, B C., are wiring the Jubilee Hospital there, and supplying the fixtures.

JACOB UNLEY has installed an electric lighting plant in New Hamburg, Ont., which is proving satisfactory.

NEIL & KENT, Granby, Que., have placed the contract for lighting their factory with Allen Taylor & Co., Waterloo, Que.

THE C.P.R. Telegraph Company has built a line from New Denver to Nelson *via* Slocan City. This line not only increases the capacity of the Kootenay systems but gives an alternating wire to the main line *via* Revelstoke.

THE Richmond Light and Power Co., Richmond, Que., is adding to its electric lighting equipment, and has placed with the Royal Electric Co., Montreal, an order for a 75 K.W. "S K.C." generator and switchboard complete.

A. H. ST. GERMAIN, North Toronto, is about to organize an autocar service between York Mills and Toronto. He has ordered three electric busses, each capable of carrying 30 passengers, from an English firm and they will be delivered in Toronto before next spring.

A COMPANY has been formed to build an electric railway between St. Catharines and Port Dalhousie. H. D. Symmes, manager of the St. Catharines and Thorold Railway, has let the contract for the cars required for the new line, and will shortly let contracts for four miles of rails, 9,500 ties and 300 poles, wire and bonding, also a 100 k.w. railway generator and several 35-h p. motors.

THE Stevens Manufacturing Co., of London, Ont., has put in dynamos for a 500-light plant for Walter Steward, Lucknow, Ont., who will supply the village with electric light. The same company has put in a 300-light plant for the village of Glencoe. The wiring in connection with these two contracts has been done by the Rogers Electric Co., of London.

THE proposed Smith's Falls Rideau and Southern Electric Railway is to be in the town of Smith's Falls, Ont., with extensions to Lombardy, Oliver's Ferry, Portland, and to Rideau Lake, Harlem, Chantry, Frankville, Toledo, Newbliss, Merrickville, Burritt's Rapids, Oxford Mills, Bishop's Mills, Easton's Corners, Irish Creek and other points within the counties of Leeds. Lanark and Grenville.

THE Toronto and York Radial Railway Company applies to the Ontario Legislature for a charter to amalgamate the Toronto and Scarborough Electric Railway, Light and Power Company, Limited; the Toronto Belt Line Railway Company; the Metropolitan Street Railway Company of Toronto; the Toronto and Mimico Electric Railway and Light Company; the Toronto Suburban Street Railway Company, Limited.

THOS. L. KAY, the well known electrician, formerly of the Kay Electrical Manufacturing Co., has recently severed connection with that firm, and is now with the Canada Electric Motor Co., who have recently started in Hamilton with good prospects. The following are some of the plants just finished:—John Duff & Son, grocers and butchers, 208 and 210 York Street, Hamilton, a 150-light dynamo with 150 incandescent and one arc light, the whole work done by the Canada Electric Motor Co. A 100-light dynamo with a number of incandescent lights installed at the waterworks of Hamilton. A motor for the St. Catharines Electric Railway. The repair of a 250-horse power generator; 8-h.p. motor for Leitch & Turnbull, elevator; motor for Bradt, grocer; a 10-light dynamo for Lees & Son, bakers, and various others. Mr. Kay is one of the pioneers in the electric business in Canada. He started in a small way on the corner of Bay and Market streets, Hamilton, in 1880, and has been connected with the business ever since. Mr. Kay was the first to exhibit a successful light in Hamilton. There were very few electric lights in Canada when he introduced his light, and now there is hardly a city or town in the Dominion where there is not a machine of his design in use. Mr. Kay has devoted the whole of his attention to electricity, the building of electric machines of all kinds, alternating or direct current dynamos, motors, transformers and all kinds of electric work. Any work entrusted to the Canada Electric Co. will receive Mr. Kay's careful attention. The works of the new company are at 32 and 34 Bay Street North. Mr. Kay has associated with him T. O. Apps, who has had considerable experience in the business department of electrical work. Mr. Apps is secretary-treasurer of the Canada Electric Motor Co.

Railway Matters.

THE G.T.R. recently brought a car load of fruit from Portland, Me., to Hamilton, Ont., 670 miles in 32 hours.

ON the eastern section of the Grand Trunk the old eight-wheel freight engines are being done away with and replaced by ten-wheel engines.

THE Signal Engineer Hodgson, of the G.T.R. engineering department, has completed the work of putting in at Woodstock, Ont., interlocking switches.

IT is the intention of the Canadian Pacific Railway Co. to keep the shops running in Winnipeg all winter, fitting up locomotives and cars for the spring traffic.

A BONUS of $75,000 to the Ottawa and New York Railway, to establish workshops in Ottawa, has been adopted by the property owners by a majority of 928.

SINCE the first of January the Intercolonial Railway, the Prince Edward Island Railway, and the leased lines, are known as the Canadian Government railway system.

THE Quebec Government has refused the $250,000 promised to the Victoria Bridge by the late Government, and also the $250,000 promised the Drummond County Railway.

THE I.C.R. management expect to reduce the number of engines between Halifax and Montreal by half, through the new and improved type recently adopted. The number now in use is twenty.

THE Grand Trunk has received 500 freight cars of 60,000 pounds capacity each, built by the Michigan Car Company, Detroit. Another lot of 500 freight cars are being built in the Canadian shops of the system.

THOS. TOMPKIN, Brockville, has been awarded the contract for the erection of a station for the C.P.R. at Vancouver, B C., also for a number of other buildings for the company in different parts of that Province.

PUBLIC meetings have been held in Toronto, and resolutions passed favoring the building of a railway to James Bay. A great deal was said about aid from the Dominion and Ontario Governments and the Toronto city council, but none of the promoters said what amount of money they were prepared to invest in what would undoubtedly prove a most valuable addition to the Canadian railway system.

THE Nova Scotia Midland Railway Company, composed of Wm Strachan, Jno. Beattie, P. Lyal, D. L. Lockerby, Wm. Mackay, S. H. Holmes, and B. F. Pearson, has signed an agreement with both the Dominion and Nova Scotia Governments, each of which subsidize the road to the extent of $3,200 per mile, for the construction of a railway from Windsor, N.S., to Truro. W. G. Reid, Montreal, has the contract to build the Midland, which is 50 miles in length.

APPLICATION will be made at the next session of Parliament by the Hudson Bay and Pacific Railway Co. for an act of amendment to their charter empowering them to abandon that portion of their projected line extending from Prince Albert to Calgary, and to establish in its stead a branch between Prince Albert and Edmonton, and also to lay out a line from Edmonton to a point on the eastern boundary of the Province of British Columbia.

ONE issue of the *Canada Gazette* contained the following applications for railway schemes in the Yukon and Kootenay countries. The Klondyke Exploration Company of London, Ont., asks for letters patent authorizing them to acquire lands and facilities for mining, smelting and transportation purposes. The applicants are: J. M. McIntyre, St. Thomas; J. A. Moody, London; D. A. McIntyre, St. Thomas; R. H. Marshall, London, and G. M. Fox, London. Molyneau St. John gives notice of application to Parliament for the incorporation of a company to construct a tramway between the head of Lake Lindemann and the mouth of the Lewis River, to avoid the White Horse Rapids and other obstructions to navigation. Lafleur & Macdougall give notice for a company to operate a railway from Fort Selkirk to a point on the international boundary, on a route towards the mouth of the Stickeen River by way of the Hootalinqua River and Teslin Lake, with branch lines. A company applies for a charter through Geoffrion, Dorion & Allan, of Montreal, to build a railway from a point on the Lewis River, between Five Fingers and Fort Seikirk and a point on the international boundary, on a route towards the mouth of the Lynn Canal, with branch lines. Notice is also given of application for an act to incorporate a company to build a railway from the head of the Lynn Canal northward along Dalton's Trail to Fort Selkirk, N.W.T.

Marine News.

THE contract for masonry on the Soulanges Canal, recently taken rom A. Stewart, has been re-let to Ryan & Macdonald.

WOODEN ship-building is being carried on with renewed vigor in Newfoundland this season. Most of these schooners are for the Labrador trade.

THERE is a rumor of a new Canadian freight line between Halifax and Liverpool, but the parties whose names are mentioned, are reticent about giving information.

JOHN & MICHAEL O'LEARY have completed their contract on the Soulanges Canal, which covered section No. 3, the approximate value of the work being $230,000.

H. E. GIDLEY, Penetanguishene, Ont., is building a fine steam yacht for W. A. Gorby, Marion, Ind. She will be fitted with compound engines and a water tube boiler.

THE Albion Iron Works Co., Victoria, B.C., is fully employed building river steamers for the Yukon and Stickeen Rivers for the C.P.R., the Hudson's Bay Co., and others.

THE Donnelly Wrecking Company, which made arrangements to release the stranded steamer "Rosedale" for $17,000, has succeeded in placing the steamer in the dry dock at Kingston.

THE Klondyke Trading and Transportation Corporation, which Sir Charles Tupper organized, has purchased the first-class steamer "Amur" from Labaun. She will run to Stickeen and to St. Michael's.

J. H. MOIR, of New Westminster, B.C., has been awarded the contract for the construction of two stern-wheel steamers for the Stickeen River route by the Hudson's Bay Company. The steamers will cost about $20,000 each.

THE Hon. J. R. Thibaudeau, the Hon. A. A. Thibaudeau, C. N. Armstrong, E. A. D. Morgan, Montreal; R. Audette, Quebec; and L. H. De Friese, London, Eng., have applied for letters patent as the Atlas Steamship Company. The chief place of business will be Montreal, and its capital $500,000.

CAPT. C. H. MCLEOD, Pictou, N.S., is now at Portsmouth, New Hampshire, where a party of Klondykers is being fitted out. The captain has secured an engagement to take a vessel round Cape Horn, or through Magellan Straits, and the party expects to be at the mouth of the River Yukon when navigation opens.

THE London manager of the Canadian Pacific Railroad confirms the report that the company has bought from the Union Steamship Line the steamers "Tartar" and "Athenian," formerly the favorite liners in the South African mail service, and will establish a regular freight and passenger communication between Vancouver and Fort Wrangel, at the mouth of the Stickeen River. Each will do the trip within three days.

A CHARTER has been granted to L. L. Beer, C. Palmer, G. J. Rogers, J. Pitblado, W. W. Beer, T. W. Dodd, A. Kennedy, W. Welsh, R. Fraser, F. L. Haszard, Charlottetown, P.E.I., to acquire by purchase, lease or otherwise, and to build steamships and other vessels, docks, wharves and other terminal facilities, and to carry on the business of a transportation company for transport of passengers and freight, as the Inland Navigation Company, Limited, with a capital of $13,200.

FOLGER BROS., Kingston, Ont., have bought the steamer "Shrewsbury" and will put her on from Clayton to Montreal, along with the "America" during the coming season. The "Shrewsbury" was built at Bath, Maine, at a cost of over $80,000 about a couple of years ago, and has been in commission only a short part of the time since. Her dimensions are 161 feet 6 inches length of keel, 26 feet 6 inches beam, 7 feet 3 inches depth of hold and 47 feet 9 inches over guards. She has compound engines of the inclined type, 25 x 46 inches, six-feet stroke. There are two boilers, Worthington condenser, steam steering gear, improved feathering paddles.

AT a meeting of the board of directors of the Richelieu & Ontario Navigation Company, it was determined to call the new steamers to be built in Toronto the "Toronto" and the "Kingston." It was resolved to make repairs to the steamer "Laprairie." She will receive new feathering wheels. Other improvements to the western fleet are now in contemplation. The details in connection with the outfit of the company's steamers generally, the improvement of their appearance, and the interior of the saloons, especially on the "Quebec," and new conveniences for state-rooms, were also resolved on. Alterations to the steamer "Berthier" will also be gone on with, with a view of increasing her speed and carrying capacity.

THE C P R has completed arrangements in Toronto, for the construction of three light draught stern-wheel steamers to ply in Alaskan waters, in conjunction with the two ocean steamers which they have purchased in Scotland. These vessels will be constructed in Toronto, the contracts having been let to the Bertram Engine Works Co for two boats, and the Polson Co for one boat. The plans have all been prepared, and work will be commenced at once, as it is intended they shall be ready for the opening of navigation. The boats are of wood, plated with steel, and will have a length of 156 feet, with a beam of 30 feet. They will be put together in the Toronto yards and will then be taken apart and the parts shipped to Vancouver. The two ocean steamers' run will be from Vancouver to Wrangel, at which point passengers will be transferred to the new light-draught boats which will ply on the Stickeen River. Captain Troop, who is superintendent of a line of steamers plying in the Kootenay district, has been, it is understood, given the position of superintendent of the new line of C P R steamers in Alaska.

Personal.

W. W. Ogilvie has presented another $1,000 to the Winnipeg general hospital.

MANAGER SKIDMORE, of the Waterworks Company, Berlin Ont., will leave shortly for the United States.

A. MCDONALD, contractor, Woodstock, Ont., was killed by a G.T.R. train at a level crossing in Woodstock, Dec. 15th.

MORTON WEBB, mining engineer, son of F. R. Webb, Petrolea, Ont., returned from Colorado for the Christmas vacation.

JAMES LAMOND, formerly with E. Leonard & Sons, London Ont., has accepted a position with the Goldie McCulloch Co., Galt.

R. MAITLAND ROY, Peterboro, Ont., who has been connected with the engineering staff of the Central Bridge Co. for a number of years, has accepted a responsible position with the Hamilton Bridge Co., and will remove to the ambitious city.

WHILE visiting at the house of a friend in Toronto, Sylvester Neelon, well known as a member of the firm of Elliott & Neelon, contractors for the masonry work at the new municipal buildings, died suddenly of apoplexy. The body was taken to St. Catharines for burial. He was 74 years of age, had lived in St. Catharines for half a century, and was prominently engaged in extensive milling and timber business. He built the large Empire flour mills, which are now occupied by the Packard Electric Co., St. Catharines. He represented the county in the Ontario Legislature. He was president, up to the time of his death, of the Niagara Central Railway Company, and it was through his work that the road was built.

HURD PETERS, engineer in charge of the harbor improvements at St. John, N.B., was the recipient of a pleasant attention from the men employed on the works. The men employed about the works assembled in the warehouse and D. C. Clark, in their behalf, read an address to Mr. Peters, expressive of appreciation of his services, his constancy in attending his duty, his zealous care in the city's interests, and his pleasing manner, which had been an encouragement to them. Mention was made that the relations between Mr. Peters and the men had always been of the most pleasing character. The address was signed on behalf of the workmen by D. C. Clark, foreman of wharf construction; Thomas Thompson, foreman of warehouse construction; D. W. Clark, superintendent of pile driving; James McMurray, captain of dredge "Cape Breton"; John W. Dickinson, captain of dredge "Freeport"; James Fennell, captain of dredge "H. F. Bothfeld"; Frank S Henrion, diver. Accompanying it was a gold headed ebony cane, suitably inscribed, also a silver ice pitcher. Thomas Thompson made the presentation of the pitcher and D. W. Clark the cane. Mr. Peters said it was usual on occasions of this kind to say it is unexpected and surprising. All can bear me out, he said, that this is utterly and absolutely true in this instance. For forty odd years I have been connected with the city's work, and sometimes have done good work, and always have had pleasant and cordial relations with the men, but never till now have they given expression to it, and that I appreciate it you must know. My schoolboy holidays were spent in Carleton from the time I was ten years of age, and I have had a great deal to do with Carleton from the time I put in the waterworks, and have always found the workmen competent and efficient. A report I prepared some time ago for presentation to the harbor improvements committee gives expression to my opinion of the excellent way in which you have worked. It gives all due credit to the foremen, but shows that the completion of the work is due to the men, who throughout have shown a friendly spirit and have worked with vigor and energy. Never was more work done, and better done, in five months; and every man who

used an axe or an adze has earnestly done his share in bringing it to a successful conclusion. Mr. Peters concluded by again thanking the men and assuring them of his good wishes, and declaring if the city undertook, as he hoped it would, the completion of the work on the other side of the slip, that they were the men for it.

—Every manufacturer of first quality paving brick is directly interested in establishing a uniform method of testing paving brick, as a matter of self preservation, for uniform tests mean impartial comparison. Hence, it behooves paving brick manufacturers, or municipal officers and city engineers to have a copy of the Report of the Paving, Brick Commission. It is a neat book of 110 pages, containing all of the comparative tables and charts compiled for the National Brick Manufacturers' Association of the U. S. by a special Commission, under the direction of Prof Edward Orton, Jr. The universal adoption of the methods recommended by the Commission will redound to the credit of paving brick and to the profit of the manufacturers. Copies may be had through THE CANADIAN ENGINEER at $1.00 per copy.

—We have received the fifty-first volume of the Canadian Almanac from the publishers, Copp, Clark Co. Limited, Toronto. Besides being a directory of clergy, militia, Government officials, members of Parliament, county and municipal officers, schools and colleges, barristers and solicitors, and other public men, it is a compendium of information of all kinds relating to Canada. Some of the more prominent departments are; Short History of Canada, Tariff of Customs Forms of Government throughout the world, Post Office Gazeteer Masonic Lodges, Miscellaneous Societies, Historical Diary, Life Insurance. Some new features for 1898 are: Short accounts of the British Army and the British Navy, with illustrations; also articles on the English Government, and Extraditions and Pardons. Besides the above, with every copy of the Canadian Almanac for 1898 is presented a map of North America, beautifully engraved and printed in five colors. The price, 25 cents.

—The annual meeting of the Atlantic and Lake Superior Railway was held in Montreal, on the 3rd inst. The President in his report said the arrangement made by Mr. Armstrong with the London syndicate was, for the present, a confidential document; but under the agreement, the company had constructed 20 miles of road between Caplin and New Carlisle, and trains are running on that section. Two parties of engineers are about to start locating the line between Paspebiac and Gaspe. The line as far as Port Daniel, 25 miles long, is an easy section, but between that point and Gaspe, several surveys will have to be made before the best route can be selected. The company has also done considerable work between Yamaska and Levis on the Great Eastern Division, grading being nearly finished between the St. Francis and Nicolet Rivers. Traffic will be open between Nicolet and St. Gregoire, and to St. Angele, opposite Three Rivers, this month. The directors have bought from the C.P.R. the section of the South Eastern between Sorel and Yamaska, including the Yamaska river bridge. This makes a connection with the South Shore Road, and the C.P.R. and United Counties Railway will pay for running rights over it. The section between Yamaska and Levis will probably be finished before the close of 1898, and wharves, warehouses, etc., will be constructed at Paspebiac, and the Government will be asked to assist in building this port. The section between Riviere du Loup and Metapedia will be 115 miles, or 60 miles shorter than the Intercolonial between the same points. This country is as yet unsettled, but is well timbered and watered, and the soil is rich. The following officers were elected: President, Hon. J. R. Thibaudeau; first vice-president, Hon. Wm. Owens; second vice-president, Hon. V. W. Larue; secretary, E. N. Armstrong; general manager, C. N. Armstrong. The three representatives of the Quebec Government, Hon. V. W. Larue, Jas. Baker, and Chas. Chaput, were continued in office.

Industrial Notes.

F. J. HENDERSON is building a butter factory at Gananoque, Ont.

THE town of Goderich is applying to the Ontario Legislature for authority to spend $50,000 in building a grain elevator.

THE E. B. Eddy Co., Hull, Que., has, it is said, entered the Diamond Match combination, and will greatly enlarge its premises as a consequence.

THE city of Hull, Que., has ordered 500 tons of pipe from the St. Lawrence Foundry Co., Toronto. The pipe will be in sizes running from 3 to 15 inches.

THE Victoria, B.C., Metallurgical Works Co., Limited, has been incorporated.

H. C. MCBRIDE, architect, London, Ont., won the competition by his plan of the Jubilee Hospital for that town.

THE Auburn Woolen Mills, Peterborough, are putting in an improved system of fire protection, and have ordered a number of hydrants, check and gate valves, from the St. Lawrence Foundry Co., Toronto.

THE Hamilton and Toronto Sewer Pipe Co. is now building an up-to-date factory, which will enable them to maintain in future the excellence of their product in the past; in the meantime, stocks on hand are sufficient for the trade till the factory is completed.

ACETYLENE gas is said to be making headway in many parts of Manitoba, particularly at Morden, where the apparatus is manufactured. The underwriters' regulations for the use of acetylene are, our readers will remember, much less severe in Manitoba than in Ontario.

THE E. B. Eddy Company, Hull, Que., is adding eight new 5x14 feet tubular boilers to the battery of 24 boilers. The new boilers are to be used as auxiliary to the present water and steam power plant, and will drive some of the small paper and printing machines, and the pumps and engines.

THE Verity Plow Company has decided to remain in Brantford. The company wants $15,000 for the old buildings, exemption from taxes and free water, an 8-inch main being necessary for the new works. The building they will erect is to cost not less than $40,000. The company will give $10,000 guarantee that they will remain in Brantford for five years, and a $5,000 guarantee for five years longer.

THE property of the Guelph Norway Iron and Steel Company was sold a short time ago for $9,700 to John Taylor, formerly employed by the company. Forty-eight thousand dollars was invested in the enterprise. Work on the building was commenced in May, 1895, operations began in January, 1896, and the mill ran off and on until May, 1897, when it was closed. The stockholders will lose everything, it is said, and the creditors get about eighty-five cents on the dollar.

A FLOOD was caused at Norwood, Ont., Dec. 15th, when the dam of the pond used to run Jas. Cummings' woolen mills gave way, and coming in contact with Nield's foundry, owned by J. L. Squier, it completely demolished it. Part of the stream entered the woolen mills and did considerable damage. The water carried away three bridges, and hundreds of cords of wood owned by J. Finlay & Son, Squier Bros., and James Cummings.

F. E. DUCKHAM, engineer of the Millwall Docks, London, England, was in Kingston, Ont., recently, with the view of getting the Canadian Engine and Locomotive Works for the building of two Duckham pneumatic grain elevators for the Montreal Pneumatic Grain Elevator Company. The pneumatic elevator, in addition to pumping grain, can transmit it horizontally 700 or 800 feet along a pipe to the warehouse and elevate it to a height of 80 feet to various bins. In loading vessels it can, it is said, handle grain at the rate of 180 tons per hour, screening, grading and weighing it in the transmission.

THE organization meeting of the Jacques Cartier Pulp Co. was held December 11th, 1897, when E. Golf Penny, Wm. Law, and W. Currie were elected trustees and Geo. McDonald, secretary, to carry on the business till incorporation is secured. This company will buy the pulp mill at St. Jeanne de Neuville, which has been sold to them by E. Bradley, C.E., for the owner, James Reid, of Quebec. The company proposes to put in new machinery to double the output. American and German experts have viewed this water-power and pronounce it unique, as nature has done most of the engineering work by a natural tunnel underground, about 600 feet long, producing a fall of 65 feet. The future capacity of the mill will be ten tons per day, mechanical.

THE terms of the agreement entered into between Abbott & Co., Montreal, and the city of Kingston, Ont., relative to the removal of the works to that city, have been made public. The company will be given a free site and a bonus of $50,000; the plant and machinery to be valued at $250,000 by a board of valuators, who will make their award ten days after the works are in running order. Abbott & Co. agree to carry on the business twenty-five years, and employ during the first year 125 to 150 hands. The pay-roll is to range from $40,000 to $50,000. Before the end of the second year the company will employ from 175 to 200 men, their pay-roll to range from $50,000 to $60,000. The city will have the first lien on the buildings and plant to the extent of the bonus for the period of twenty years, and the works must be operated 275 days in each year.

PARRSBORO', N.S., will spend $4,000 on firehall equipment.

A PEQUEGNAT'S bicycle factory, Berlin, Ont., is being equipped.

JAS. CAMERON, Fallbrook, Ont., is starting a sawmill at Harper.

A NEW market building is proposed for Brantford, Ont., to cost $4,000.

THE city of Ottawa purposes to spend $70,000 on buildings in Lansdowne Park.

E. R. SIMPSON & Co., engineers and machinists have begun business in Berlin, Ont.

WINNIPEG will spend $700,000 on a system of water works, to be supplied from artesian wells.

THE Welland Vale Bicycle Co., St. Catharines, Ont., is manufacturing a chainless bicycle for next season.

THE Rathbun Company, Deseronto, Ont., has been shipping carloads of doors, etc., to South Africa, recently.

W. P. NILES may build a roller flour mill at Wellington, Ont., the village having granted exemption from taxes.

A. E. CARPENTER has sold out his interests in the Hamilton and Toronto Sewer Pipe Company to Henry New.

E. L. PERKINS and W. H. Heine are interested in organizing a wood-working company, at Norton Station, N.B.

THE Canada Screw Co., Hamilton, Ont., is applying for an extension of the exemptions enjoyed for some years past.

H. & F. GIDDINGS & Co., Granby, Que., will build a new furniture factory, 50 by 100 feet, and five stories high, in the spring.

THE Exploits Lumber Co. is to be incorporated to do a large lumber business in Newfoundland. The capital is English.

IT is said that a combine including every wire rod, nail, and other wire product in the United States will be in operation before Feb. 1st.

GEORGE MCARTHUR, St. John, N.B., has been awarded the contract for building Doran's Hotel, Windsor. The contract price is over $20,000.

THE work of enlarging and improving the Rathbun Company's cement works, at Napanee Mills, Ont., is being pushed by a large staff of men.

THE town of Wardner, B.C., which has grown up where the Crow's Nest Pass Railway is to cross the Kootenay River, is experiencing quite a boom.

THE Dominion Elevator Company is now erecting elevators at the following points: South Edmonton, 20,000 bushels; Laduc, Wetaskiwin, and Red Deer, 15,000 each.

THE town of Welland, Ont., is to be piped at once for a natural gas supply. The rates charged will be the same as in Dunnville, Ont., *i.e.*, $35 a year for furnace; $24 for a cook stove; $19.35 for a heater.

AN order has been received at the C.P.R. car shops, at Perth, Ont., to build 20 first-class passenger cars and 10 sleepers. Hitherto only freight and box cars have been manufactured at the Perth shops.

INCORPORATION has been granted to M. M. Boyd, W. T. C. Boyd, Bobcaygeon, Ont.; G. Boyd, J. Wickham, Toronto; J. D. Flavelle, and J. G. Edwards, Lindsay, as the Cowichan Lumber Co., Limited. Capital, $150,000.

THE case of Dale *v.* the Riordon Paper Mills, Limited, Merritton, Ont., has been settled for $1,500 out of court. James Dale, who was severely scalded at the mill some months ago, brought an action for $2,500 against the company.

J. T. CHILD, C.E., of Child & Wilson, Calgary, N.W.T., was at Lethbridge recently making an estimate of the probable cost of a system of waterworks for that town. Medicine Hat is also looking for a waterworks system, it is said.

C. GUIMOND, Beauharnois; C. F. Lalonde, Montreal; J. Leduc, J. B. Roy, Delia Rochette, Beauharnois, Que, are applying for a Dominion Charter as the Star Iron Company, Limited, to manufacture furnaces, etc. Chief place of business, Montreal; capital, $60,000.

THOS. DOHERTY, Sarnia, Ont., the inventor of the famous iron casting process, is now engaged upon the invention of a further improvement in this process of iron production, of which great things are predicted by those who have been given an inkling of the new idea.

THE creditors of Robert Saxby, engineers' supplies, Toronto, met recently, when a statement was presented showing liabilities of $3,200, with assets of about $4,000. The chief claims are: John Herrington estate $1 700, secured by a $1,000 mortgage and $300 note, endorsed; E. E. Cooch $550, Bank of Commerce $100, Royal Oil Company $125, and Robert Saxbury, jr., $300. The assets consist of land $3,500 and the remainder stock and book debts.

THE company which is working the peat beds near Welland, Ont., is going into the manufacture of artificial marble from gypsum.

THE city engineer, Montreal, has asked an appropriation of over $1,000,000, chiefly to be spent on new sewers and enlarging old ones.

THE town of Magog, Que., has recently installed a municipal electric lighting plant, and now proposes to add a system of water supply, the same power plant being used as for the lighting system, and the pumping being all done during the day when there is no demand for electricity.

J. M. LAVOIE, E. Lavoie, O. Matton, Ottawa; A Lavoie, Donald, B.C.: J. M. McDougall, Hull, Que, have been incorporated under the Dominion statute as the Lake Deschenes Milling Company, Limited, with a total capital stock of $40,000, to build flour and other mills, and do a general milling business.

THE average nightly attendance at the Toronto Technical School was 230 during October and November. The building is to be enlarged for the use of the school by the University of Toronto, which owns it, at an expense of $26,000. The Technical School will pay a rental of $2,000 per year for 21 years.

PLANS have been brought forward for extending the Bonsecours market, Montreal. The plan would extend the market to Jacques Cartier square, and then take in property and land on St. Paul, Bonsecours and Leroyer streets, extending the latter street through to Bonsecours street; a large square would thus be added to the market.

THE Ontario Sewer Pipe Company, Mimico, Ont, has completed what is said to be the largest sewer pipe kiln in the world. It measures 36 feet 7 inches in diameter, seven inches larger than the one built by the Great Western Sewer Pipe Company, Ohio, and about 19 inches larger than those of the Black Horse Sewer Pipe Company, Virginia

THE Acton Tanning Co. and Beardmore & Co., Acton, Ont., are putting up new buildings. The carpenters are busy on two new hair houses, one for each establishment, 32 x 50. J. A Speight & Co. are finishing two large cedar water tanks for the Acton Tanning Co., fifty-seven feet in circumference and twelve feet deep.—*Acton Free Press*, Nov. 25.

A NEW company has been formed to operate the Coldbrook Rolling Mills, near St. John, N.B. The new company, which is styled the Coldbrook Steel and Iron Company, has appointed W. H. Thorne & Co., wholesale hardware merchants of St. John, as their selling agents, The company will manufacture bar iron, railway spikes, and wrought spikes.

A PRACTICAL demonstration of a new process of jointing pipes took place recently at the Caledonia Iron Works, Montreal, in the presence of some influential pipe-makers, contractors and others. The process of making and fixing the ring joint is an entirely new departure from the customary methods employed in jointing pipes, and overcomes the difficulties incidental to pouring and caulking lead into pipe joints in wet trenches. A full description of this process appears in THE CANADIAN ENGINEER. The inventor is D. J. Russell Duncan, C.E., 28 Victoria street, London, S.W. The ring joint is made with cold sheet lead, which is circumferentially contracted and indented by the pressure of a contractible tapering wedge and an external compression ring.

IN connection with the mention made in past issues of THE CANADIAN ENGINEER of the different appearances of strange aerial bodies, by many believed to be air-ships, the following press despatch, dated from Pittsburg, Pa., may be of interest: "It has at last been discovered who the incorporators of the Atlantic and Pacific Aerial Navigation Company are. The company, which is officered by C. A. Smith, president, and M. A. Terry, secretary, both of San Francisco, was organized to manufacture the air-ship of Hiram S. Maxim, inventor of the Maxim gun. It is said by persons connected with the company that last summer a trip was made in a Maxim air-ship from San Francisco to Cleveland and back in three days. Mr. Maxim furnishes the following description of his vessel: It occupies 106,000 cubic feet of space. The propelling power is a 105 horse-power naphtha engine. The cylinder engine and all other parts of the machine, so far as practicable, are made of aluminum, which was purchased of the Reduction Company here. The ship now weighs about 5,000 pounds, and will, its friends claim, carry more than a ton weight of provisions and passengers. The naphtha for the engine will be stored in cases, which are supposed to hold enough to drive the ship around the earth without replenishing the tanks. The tail that projects upwards from the stern of the ship is intended to direct it up or down as a bird directs its movements with its tail. The rudder is to change the course from right to left. Motive power is secured by the big aeroplane at the stern, which is driven by the naphtha engine. It is stated that a speed of one hundred miles an hour has been attained without straining the machinery."

MONAGHAN & SUTHERLAND, contractors, Halifax, N.S., assigned not long ago to T. Frank Courtney.

THE Strathroy Furniture Co. is building a sawmill in connection with its factory, capacity, 15,000 feet per day.

RICHARD SCHOFIELD, Toronto, recently put in an electric mail-marking machine in the Hamilton Post Office.

POWER & SON, architects, Kingston, Ont., are preparing plans for a new elevator for Richardson Bros., Kingston.

AN acetylene gas company is to be established in Carleton Place, Ont., and has already asked for street privileges.

THE Goldie & McCulloch Co., Galt, Ont., recently shipped a large boiler to the Ontario Rolling Mills Co., Hamilton.

THE Methodists of Brandon, Man., will build a $30,000 church next season. S A. Bedford is chairman of the building committee.

HARLAND BROS., Clinton, Ont., hardware, are putting in a 40-light acetylene machine and will furnish some neighboring firms with light.

THE Waterloo, Que., waterworks, owned by Gould & Wilson, will shortly pass into the possession of the municipality, which gives in the neighborhood of $21,000 for them.

Two carloads of screens from the Jenckes Machine Co., Sherbrooke, were received at the mills of the Chicoutimi Pulp Co. recently, and are now being set in place.

THE Montreal City Bill, now before the Quebec Legislature, proposes to give the city the right to borrow $250,000 for the extension and improvement of Bonsecours market.

THE Canadian Typograph Co , manufacturers of the well-known E. & D. bicycles, have received orders for 150 of their wheels from South Africa, nearly 100 of which have already been shipped.

FOUR municipal by-laws were voted on in Galt, Ont., Jan. 3rd, all of which were defeated, viz. : $7,000 for market extension; $8,000 for new fire hall ; $3,000 for hospital sewer ; $1,800 for electric fire alarm.

THE Windsor, N S., Plaster Co. commenced grinding plaster early in December, and is now able to supply the celebrated Selenic Cement. This is the first manufactory in Windsor to begin work after the fire.

THE plant of the Phelps Machine Co., Eastman, Que , has been bought out by the Jenckes Machine Co., of Sherbrooke, which will continue the manufacture of the Dake engine in the Sherbrooke works.

THE City of Belleville, Ont., owns its gas works. The original investment was $14.400. The dividends in twenty years have amounted to $28 224 in addition to two per cent. which has been put aside each year for repairs and improvements.

R. MACKIE has been appointed engineer of the new sewage disposal works, Hamilton, Ont., at a salary of $600. Mr. Mackie holds a first-class certificate, and has been engineer at the Hamilton Bridge Co., the Copp Bros., Limited, and the Rolling Mills.

AT the annual shareholders' meeting of the Dominion Wire Manufacturing Co., Montreal, the following directors were elected by the shareholders : James Cooper, president ; C. W. Vollmann, vice-president; J. C. McCormick, managing director ; F. W. Fairman, H. Horsfall.

AT the annual meeting of the Montreal Metal and Hardware Association the following officers were elected : President, George E. Drummond; vice-president, J. B. Learmont ; treasurer, J. W. Pyke ; directors, Charles Cassills, Frank Caverhill, Robt. Gardner, and C. L. Letang. A resolution was passed endorsing the limitation of credit to four months and 3 per cent. for cash.

WATER was let into the penstock at the pulp mills at Chicoutimi on the 15th ult. The mill, it is expected, will be in full operation by the 20th. The development of the water power in connection with the mill was undertaken by the Jenckes Machine Co., of Sherbrooke, Que., which used four special Crocker wheels for the purpose. The wheels give excellent satisfaction under the usual head of 70 feet.

DR. C. J. EDGAR, North Hatley, Que., has formed a partnership with W. O. Roy, of Montreal, and acquired a water power on the Massawippi River, a little below the village. They will furnish electric lights and power to North Hatley, Eustis and Waterville. A contract has been made with the Jenckes Machine Co., Sherbrooke, Que., for developing the power, and the whole plant will be put in at once.

J. P. CARRITTE, St. John, N.B., and J. W. Patterson, of the Patterson Manufacturing Company, Montreal, have contracted with the People's Heat and Light Company, Halifax, N.S., for the company's tar output, and will have erected as soon as possible a factory on the North-West Arm, for the manufacture of tarred roofing and building paper, and all bi-products of tar. They have bought plant in New York, and plans have been prepared for the buildings. The works will be ready for operation in the latter part of February, it is expected.

YARMOUTH, N.S., will build a $15,000 school.

THE reservoir of the Parrsboro, N.S., waterworks has been completed.

E. D. SMITH, Winona, Ont., fruit grower, is spending $5,000 on a cold storage warehouse.

THE Detroit Lubricator Co. has recently received orders for 100 locomotive lubricators, which are to be shipped to China and Japan.

MADISON WILLIAMS, who is now proprietor of the foundry and machine shop of the Paxton, Tate & Co. estate, Port Perry, Ont., is doing a good business.

THE new pulp mills of the Royal Paper Mills Co. at East Angus, Que., are rapidly nearing completion. The contract for the entire tank work has been awarded to the Jenckes Machine Co., Sherbrooke, Que.

THE Rev. D. B. Marsh, Black Heath, Ont., inventor of the Marsh stethophone, is now taking out patents in the United States and several European countries. Mr. Marsh has made a number of improvements on the instrument since the patent first issued in Canada

THE trouble between the Customs Department and the Canadian agents of the La France Engine Company has been settled by the payment of $441 additional duty and fine. The company, in a letter, gave the lowest price of the engine as $4,200. When it reached Canada it was entered at $3,570, that is 15 per cent. less than $4,200, This $630 was understood to have been the Canadian agents' commission at 15 per cent. The Customs authorities have now decided that the correct value for duty was $4 300, and has collected 35 per cent. on this $630 deducted, with a fine of 100 per cent. on the amount of undervaluation.

SINCE the publication of the article on towns' water supply in our June number, which points out the poisonous effects of lead pipe on drinking water, we have received from E. Walker & Co., water pipe manufacturers, Heckmondwike, Yorkshire, England, a sample of their wrought iron pipe lined to a thickness of over one-sixteenth of an inch with block tin, and a suitable connecting coupling lined so that the water cannot possibly come in contact with the iron, even at the joinings. They also make iron pipe with a non-conducting material or insulator placed between the iron pipe and the block tin lining, which they claim prevents frost penetrating the pipe and freezing the water. This overcomes the difficulty pointed out, and supplies a pipe almost everlasting in wear, and that cannot rust, or in any way destroy the purity of the water. The sample can be seen at the office of THE CANADIAN ENGINEER.

J O. LA FOREST, superintendent of the Montreal waterworks, has again called the attention of the city council to the danger that will attend further neglect of the long-needed waterworks extensions. The high level reservoir contains about 1,750,000 gallons, or less than 24 hours' supply for the district it serves ; while the only engine capable of duty at the McTavish street station is worked beyond its capacity, so that there is no time for overhauling in case of accident. The water supplied from the high level reservoir has increased enormously in recent years. In 1885 it was 48 986,086 gallons, while in 1896 it had risen to 662,572,822 gallons. A new engine is urgently needed at a cost of about $40,000, including erection, and an additional boiler at a cost of $19,650, including alterations to the buildings. The cost of connecting the two sections of the reservoirs to the suction pipe, and the continuation of the 20-inch main to the high level reservoir, will add about $10 000 more to the cost of the needed improvements.

To the first person sending us The Canadian Engineer of December, 1893, or March, 1894, we will pay 50 cents or one year's subscription, or we will pay $2 cash or three years' subscription to any one who will send us Volume I complete.—Biggar, Samuel & Co., 62 Church St., Toronto.

For Sale Cheap

A New 100 Kilowatt 125 Volt Multipolar, Direct Current Dynamo

Latest steel frame type, with iron clad armature.

A most complete set of Station Attachments. Suitable for Incandescent Lighting, with a capacity of 2,000 16-candle power lamps, or for power or electro-chemical purposes ; has never been used only for a test.

For particulars apply to E H. HILBORN, 74 Brunswick Avenue, Toronto, or to JOHN TOLMIE, Kincardine.

The Ontario People's Salt and Soda Company, Limited

The Canadian Engineer

VOL. V.—No. 10. TORONTO AND MONTREAL, FEBRUARY, 1898. PRICE, 10 CENTS $1.00 PER YEAR.

The Canadian Engineer.

ISSUED MONTHLY IN THE INTERESTS OF THE

CIVIL, MECHANICAL, ELECTRICAL, LOCOMOTIVE, STATIONARY, MARINE, MINING AND SANITARY ENGINEER, THE SURVEYOR, THE MANUFACTURER, THE CONTRACTOR AND THE MERCHANT IN THE METAL TRADES.

SUBSCRIPTION—Canada and the United States, $1.00 per year; Great Britain and foreign, 6s. Advertising rates on application.

RAILWAY ENGINEERING.*

BY CECIL B. SMITH, MA. E., MEM. CAN. SOC. C.E., ASSISTANT PROF. OF CIVIL ENGINEERING IN M'GILL UNIVERSITY.

CHAP. V.

ROADBED CONSTRUCTION.

ARTICLE 23.—MASONRY BRIDGE PIERS.

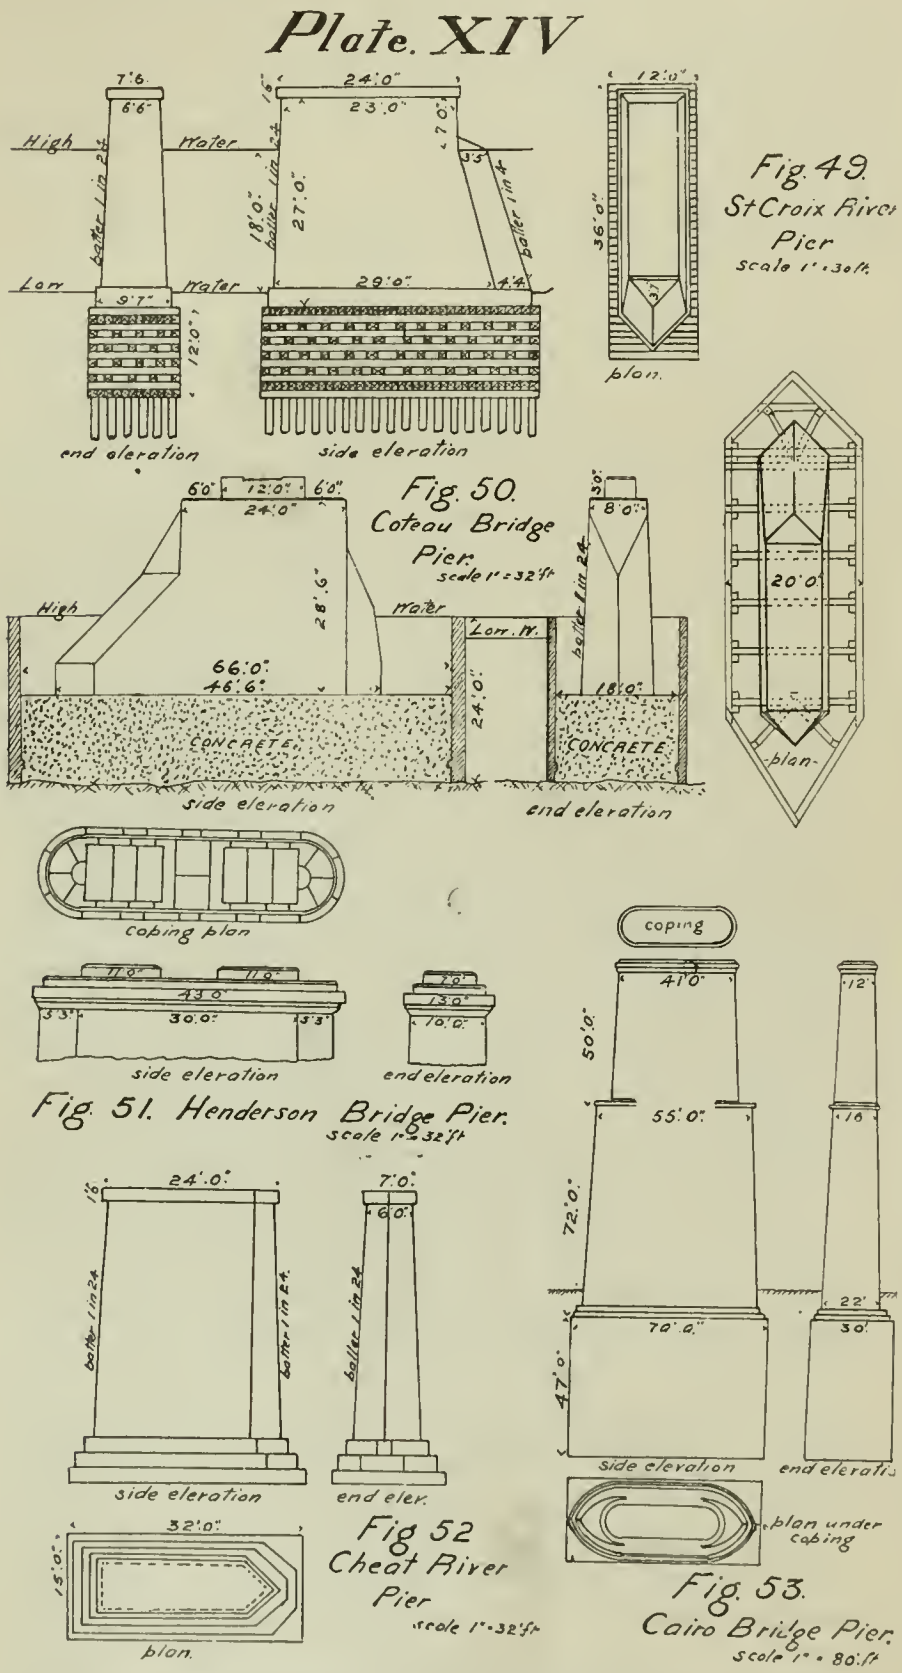
The material most commonly used for masonry pier construction is stone, although in certain cases brick may be cheaper and also satisfactory; but wherever there are strong currents of water or jams of ice or logs, brick is hardly suitable, as the individual pieces are liable to displacement; but concrete piers are becoming quite common in certain parts of America, the compact and simple form of a pier lends itself readily to concrete construction, the ebb and flow of tides will not affect well made concrete whereas it has a disastrous effect often even on the heaviest class of masonry, percolating through the many joints loosening the stones and mortar; concrete piers are usually much cheaper than first-class masonry work, and even the compromise of a pier with the sides and top of stone and the interior of concrete, offers considerable saving. In designing piers located in river beds we have three special questions to study, namely, the dimensions and construction of the coping, the batter of the sides to insure stability, and the design of the cutwaters; of course the question of foundations enters into designing this class of work even more seriously than with structures built on land, but the subject of foundations will be taken up in a more general way applicable to all structures.

(1) The coping dimensions will be determined by the width apart of the trusses, the size of the bed-plates, and the loads to be carried locally on the masonry work, the variation would be for single track roads, from say 4 feet by 16 feet under coping for small deck trusses to as large as 12 feet by 40 feet for long through spans. The coping should project two or three feet beyond the bed-plates at the ends, and six inches to two feet at the sides, depending on the weight of the span. Copings should consist of an 18-inch thickness of very strong carefully made concrete, surfaced with a layer of 1 to 1 mortar before the concrete has set, or if of stones, they should be large, well-bedded, cut all over the top surfaces by fine pointing, pean hammering, or in some way giving a good surface for the bed-plates; the vertical joints should be cut and preferably the beds also; but the faces look better with the quarry face left on, if the rest of the pier is rock faced ashlar. They should be dowelled into place, or clamped to one another, and so arranged that the pedestal plates of the bridge trusses will come *exactly* on the centre of a large stone, or if one stone cannot be found large enough to distribute the load, a large, deep pedestal block should be cut for the purpose and placed on top of the coping; for very large trusses, a steel pedestal is constructed to distribute the load over several coping stones (*e.g.*, new Victoria Bridge). Coping plans showing the exact size and position of each stone should be furnished the contractors, and it is a mooted question, whether better results as to exact surface, etc., can be obtained by bedding in mortar, or by shimming up the whole coping to an exact level on wooden chips, then pointing up all the outer bed and vertical joints, and pouring liquid grout into the receptacle of interior joints and beds thus formed until every crevice is filled, the latter plan is probably preferable, if care is taken to have the joints and beds open enough to secure their being thoroughly filled, particularly the beds.

(2) The batter of the sides is usually 1 in 12 or 1 in 24 and is a matter of appearance, as vertical piers would look top heavy, but in each case a calculation should be made for stability, under the most unfavorable circumstances; considering the stability in direction of the railway line, the forces acting would be (*a*) the wind blowing at 45° to the direction of truss, on the truss, train and pier, at say 40 lbs. per square foot, the force of a fully braked train covering one or two spans depending on the location of the expansion rollers, at say, 10 per cent. of the weight of the train, and vertical loads which would consist of a *loaded* span and the weight of the pier itself; the resultant of these forces should not fall appreciably outside the middle third of the base, (*b*) with the wind as before, but

*This series of papers will be issued in book form as soon as they have appeared in THE CANADIAN ENGINEER.

blowing on the truss and pier only, and the vertical loads of an *unloaded* span and the weight of the pier itself, the same criterion for stability should be applied as in (*a*), and in either case the remedy for instability would be to increase the batter, or introduce steps or offsets of, say, 6 inches every 10 or 12 feet, which would have the same effect. The stability of a pier at right angles to the bridge is practically never in question unless of very great height, in which case similar tests would determine what the necessary length of base should be.



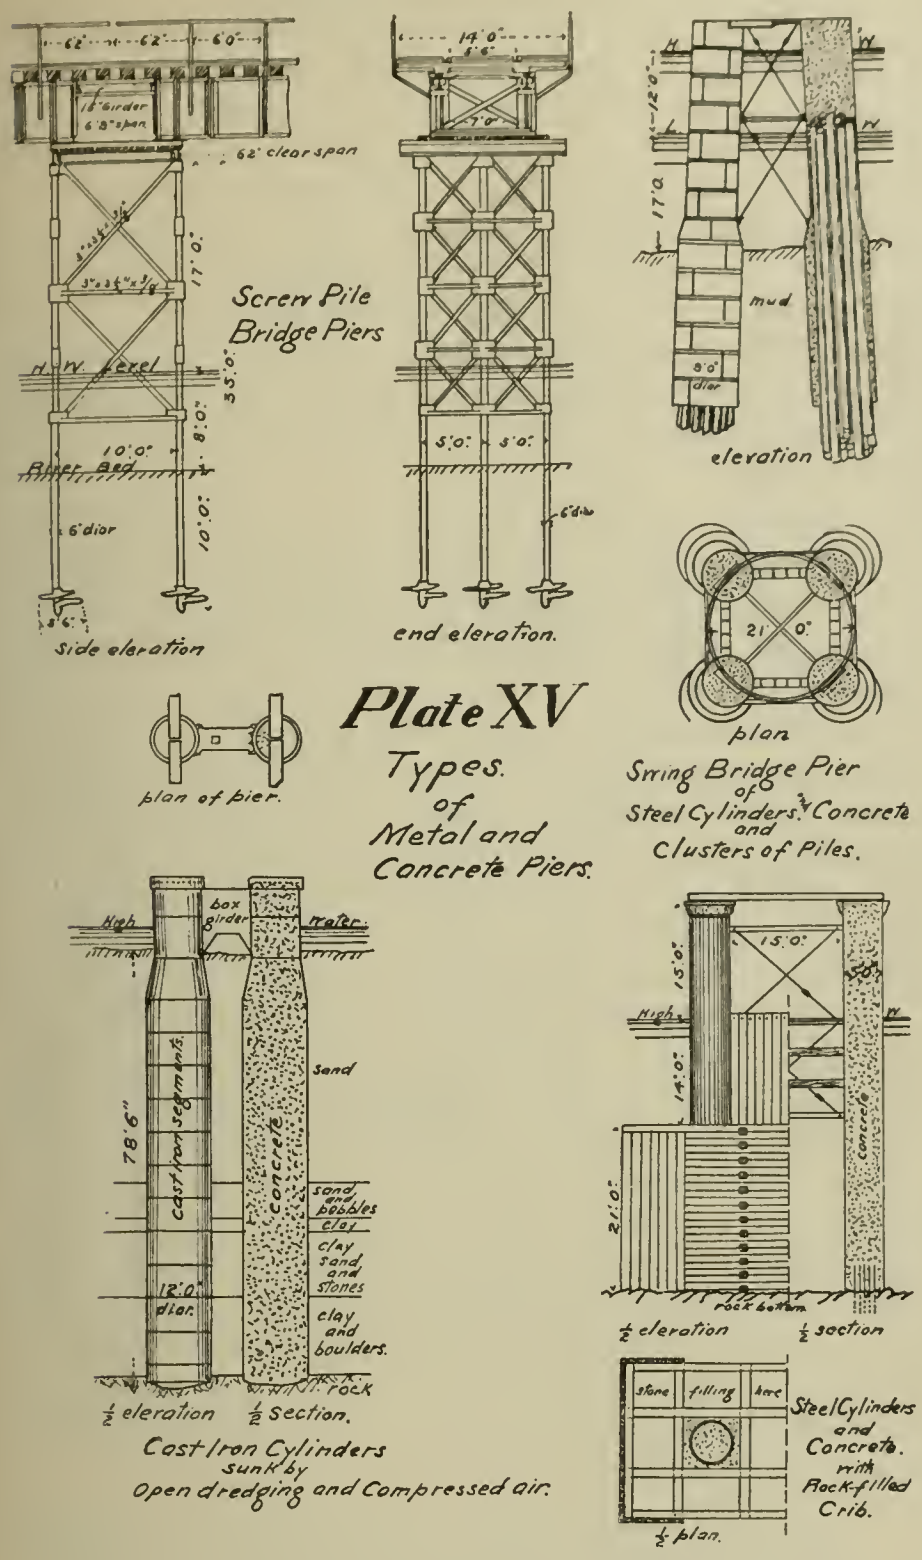
(3) Cutwater designs:—Wherever there is any appreciable current in a river, it is necessary to construct the up-stream end of the pier of such a form that it will divide masses of driftwood, ice, logs, etc., as well as the current itself. Probably the simplest form is that shown in Fig. 52, which will not cost appreciably more to construct than a square pier, as the nose is a right angle and the faces of ordinary quarry-faced ashlar, but such a form is suitable only for streams carrying light ice or moderate jams of logs; in place of this the more ornamental forms shown in Figs. 51 and 53 would be equally satisfactory, especially the latter, but cost considerably more, and should therefore be used only on very important structures.

Where piers are to be placed in swift currents, or in any stream carrying heavy jams of logs, or thick floes of ice, their cutwaters should be of designs similar to Figs. 49 or 50. The cutwater of the former hardly extends high enough and is not flat enough for Canadian rivers, and besides it lacks the valuable addition of a small pointed lower end, which is introduced to eliminate an eddy at that point in swift currents, which tends to undermine the end of the pier, unless on solid rock. Probably the St. Croix pier and cutwater are suitable for the conditions they were designed for, but the intention of the design on Fig. 50 is that the jams will rise on the nose and split in two, passing on harmlessly.

Stone masonry bridge piers will cost from $9 to $15 per cubic yard, depending on their height, size and the cost of quarrying, transporting and cutting suitable stone. If expensive cutwaters are needed this will add to the cost; those used under severe conditions being of a first-class cut stone construction of large dimensions, clamped together and dowelled also, with a strip of boiler plate added to the nose to prevent dislodgement of stones. The following specification of first-class bridge masonry will apply to both abutment and pier construction, but in many cases a less severe specification has resulted in satisfactory and durable work.

Specification for First-Class Bridge Masonry.—"This class of masonry will be ranged rockwork of the best description, from stone of approved weathering qualities, and will be laid in suitable cement mortar (1 to 2 natural, or 1 to 3 Portland). The face stones will be accurately squared, jointed and bedded, and laid in courses not less than 12 inches thick, decreasing in thickness from bottom to top of walls; the joints and beds to be less than half-inch and joints well broken, no break to be less than nine inches. The stretchers to average at least $3\frac{1}{2}$ feet in length with 3 feet as a minimum, to have at least 16 inches bed, and always at least as much bed as rise. The headers to have a width of not less than 18 inches, and to hold the size back into the heart of the wall that they show on the face; they shall occupy at least one-fifth of the area of the face of the wall, and be practically evenly distributed over it, so that the headers in each course shall divide equally or nearly so, the spaces between the headers in the next course below. When the walls are not more than $3\frac{1}{2}$ feet thick, the headers shall run entirely through, and when between $3\frac{1}{2}$ and 6 feet thick, there shall be as many headers of the same size in the rear as the front of the wall, and the front and rear headers must alternate and interlock at least 12 inches with each other. In walls over 6 feet thick, the headers shall be at least $3\frac{1}{2}$ feet long, alternating front and back as just described, their binding effect being carried through the wall by intermediate headers of a similar character. The stretchers in the rear of the wall, and the stones in the heart of the wall shall be of the same general dimensions and proportions as the face stones with equally good bed and bond, but with less attention to vertical joints, and must be well fitted to their places, and carry the course evenly quite through the wall; a header shall in no case have a joint directly above or below it, but rest entirely on a stretcher at the face; any small interstices that may remain in the heart of the wall shall be carefully filled with mortar and spauls. The face stones shall be left rough on the face, with no projection of more than three inches from pitch lines, and two-inch drafts will, in general, be carried up and around all projecting angles. In the construction of piers, it is understood that the description above given for face work shall apply to both ends and both sides of the pier. Copings are to be cut and dowelled or clamped according to coping plans furnished, the top shall be crandalled and pean-hammered,

or otherwise brought to a smooth surface, and so arranged as to bring the pedestal plates of the trusses exactly on the centre of especially large coping stones of dimensions given on the plans."



ARTICLE 24.—METAL OR METAL AND CONCRETE PIERS.

On Plate XV. are shown several applications of metal and concrete for bridge piers. The method by screw piles founded in mud is quite unique and has not been attempted in America for railway bridge piers, but the steel cylinders filled with concrete and founded either in mud on piles or anchored to the rock by iron dowels are more familiar. For light highway bridges this method is quite suitable, but it is probable that, except in the form of one large cylinder, as a cofferdam to a pneumatic caisson, both filled with concrete and sunk in waters not needing cutwaters, their use for railway bridge piers will be exceptional, as the more massive forms shown on Plate XIV. will be better able to withstand the vibrations of trains and impacts of ice, etc.

ARTICLE 25.—IRON VIADUCTS OR TRESTLES.

The features usually under the control of the railway engineer are the general lay-out, the design and construction of masonry, and the erection of iron work; the detail designing of the iron being essentially a branch of bridge-work.

(*a*) *General lay-out.*—This has resolved itself in America to be, in general, a system of braced independent towers and suspended spans (see Fig. 54); the towers are usually about 30 feet spans, with posts vertical in side elevation; and, in end elevation, the girders are spaced 8 to 10 feet centres, and the posts battered at 2 to 3 inches per foot, depending on the allowance for wind, the aim being to avoid tension in the windward pedestals at the most unfavorable instant. The suspended spans are usually also plate girders of 30 feet to 60 feet span, depending on the height, the greatest economy being claimed when the cost of girders and longitudinal bracing is equal to the cost of towers and pedestal masonry. The usual design is with diagonal rods acting in tension and the girders resting on top of the posts, with slotted holes for expansion, but some late designs are for rigid, riveted bracing and posts extending to the tops of the girders, which are riveted to the webs of the posts, temperature changes being taken up in expansion pockets every 100 to 200 feet. This system is theoretically more rigid, but costs more and demands a perfect system of pedestals, any settlement being dangerous to a proper distribution of stress.

In estimating the weight of iron for approximate work, the following rule may be useful:

The weight of metal in the towers and bracings, in pounds, is equal to about $8\frac{1}{2}$ times the longitudinal section area in square feet of the ravine below the line of girders and between the faces of abutments; this is based on a 100-ton consolidation engine and a high viaduct, say 100 feet, this will be changed to say $9\frac{1}{2}$ times for a viaduct 50 feet high, and $10\frac{1}{2}$ for a viaduct 35 feet high with the same weight of engine. The weight of girders, in pounds, may be estimated at $(9l+100)$ pounds per foot run of a span, where l = length of span. The price of iron varies considerably, with cost of erecting falsework, if any, and cost of erection and freight in general, but is about four cents per pound, in place, as a minimum. The floors of viaducts usually consist of say 8-inch by 10-inch oak ties about 12 feet long on their edge, boxed one-inch over the girders, and fastened to them by hooked bolts which pass through the guard rails and hook under the upper girder flanges; the spacing should be not more than six inches clear, and guard rails either double or with an inner guard rail of ordinary flanged rail. Some recent designs, however, call for solid floors of steel troughs filled with ballast and with ordinary track ties, which, certainly, would lessen vibration and increase safety in case of slight derailments.

(*b*) *Pedestal Masonry.*—The greatest care must be exercised in laying out and building the abutments and pedestals, as any error in position or appreciable one in height is very serious, because the iron work, being manufactured at a distance contemporaneously with the masonry, is shipped to the spot partially assembled, and cannot be afterwards altered except by a slight shimming up of pedestals built too low. The shoes of the columns are always bolted down to the copings, and in high structures these bolts should be built into the pedestals 5 or 6 feet, by passing through the stones as they are laid in place (see Fig. 54), the bolt holes are afterwards filled tight with sulphur, lead, or neat cement grout, while if the structure is not very high or subject to heavy winds, the anchor bolts are only sunk into the coping stones, dovetailed by wedges and cemented as before. Pedestal masonry is sometimes built of well burnt brick covered by a stone coping, and the use of monolithic concrete is especially adapted to this class of work, as it permits of the anchor bolts being buried in the concrete to any depth during construction. In any case the best class of work must be done, as the strains and thrusts acting are of higher intensity than in ordinary masonry, and the pedestal is not only under considerable vibration for so small a

mass, but may be put in tension on the windward side of high structures. The cost of stone pedestal masonry will vary with the conveniences for handling small quantities of large stones at each spot, and with the amount of cutting required, from $10 to $15 per cubic yard, whereas a very high class of concrete may be done for at the most $8 per yard as there is nothing to move from place to place but the plank molds and mortar box. The coping of concrete pedestals should be made very strong, say, 1 cement, 1½ sand, 3 stone, with a layer of 1 to 1 mortar for 1½ or 2 inches thick on the top and sides, put on at the same time as the rest is being built, and incorporated with it by vigorous trowelling and ramming, etc.

Plate XVI

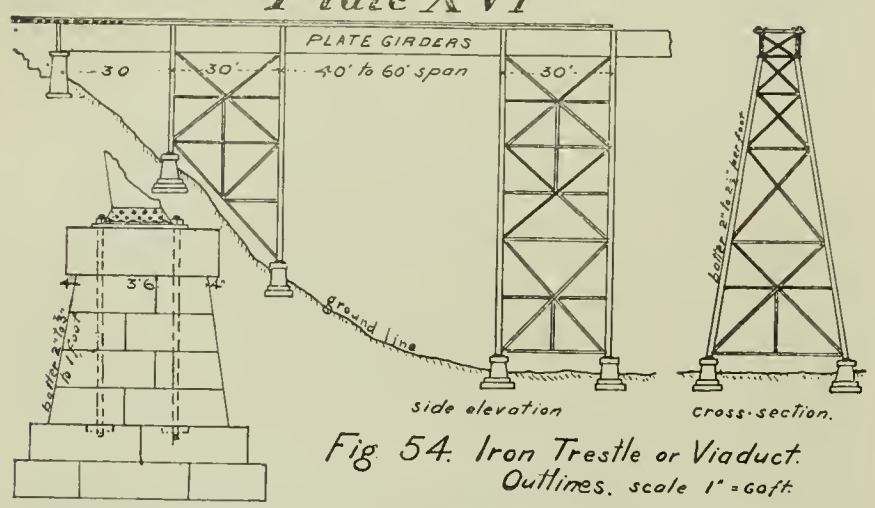


Fig. 54. Iron Trestle or Viaduct. Outlines. scale 1" = 60ft.

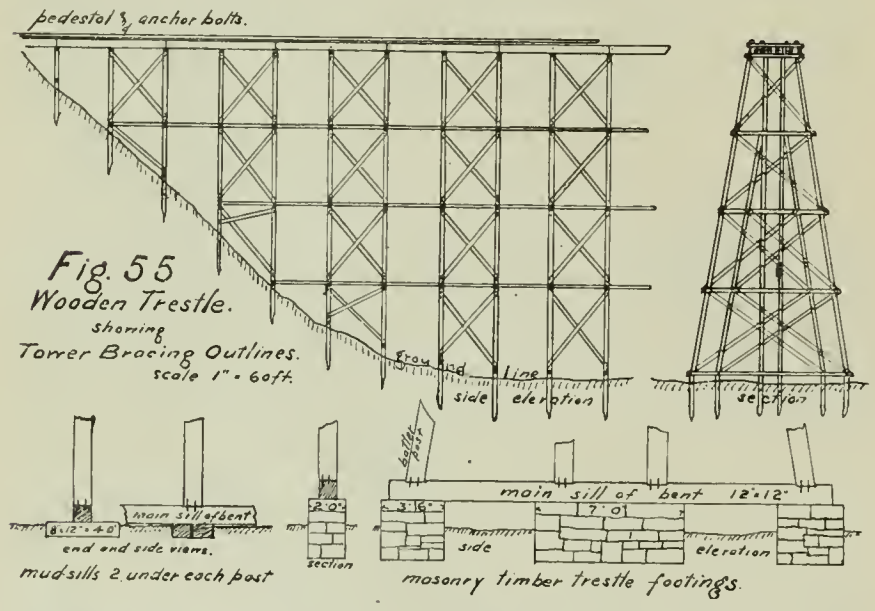

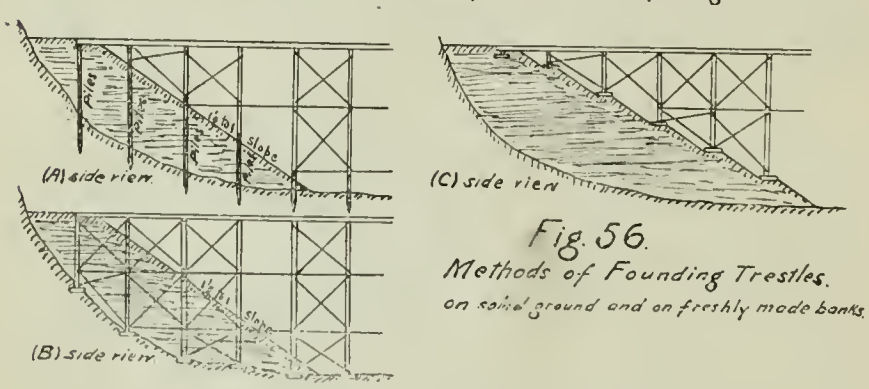

Article 26.—Wooden Trestles.

In America where timber is plentiful, cheap and widely distributed, where capital is often limited and construction hurried, and in inaccessible regions, the use of wooden trestles has been of great economic value. It is yet a factor not to despised; and although their design is apparently not very difficult, yet it should be thoroughly understood by the young railway engineer in its many phases at an early date in his practice. We have probably 100 feet per mile of railway in Canada, or about 300 miles altogether, and we may safely figure on a continual renewal of at least half of this every seven or eight years, which represents an annual drain on our forests for this purpose of perhaps 40,000,000 F.B.M., while the other half will be replaced by earth, stone or iron as fast as it decays. Gradual separation and sizes of timber available have produced several distinct types, each of which has its advocates; the greatest diversity exists in every detail from floor to foundation, and will be discussed somewhat, in order to obtain a broad view of the various methods in use.

(*a*) *Foundations.* — These may be classed as (1) masonry footings, (2) piles, and (3) mudsills.

(1) Stone work suitable for culvert walls is used for the masonry footings and will cost about $4 per cubic yard; the heaviest and longest stones should be used for the top course, and the sill well bedded on it in mortar. It is not necessary to bolt the sills to the masonry if the timber bents are braced longitudinally; and, sometimes, where it is anticipated that an iron viaduct will replace the wooden one at the first renewal, it may pay to build the batter post pedestals under every alternate bent, of first-class pedestal masonry, which will serve as pedestals for the columns of the iron viaduct when needed (see Fig. 56).

(2) When foundations are deep or soft, or less expense is desirable, a pile is driven under each post of each bent, and the sills rest on and are drift-bolted or tenoned to the piles; for 15-foot bents and a 100-ton engine, a pile will carry one-quarter of the load on a bent when it penetrates less than about two inches under a blow from a 2,000-pound hammer dropping 25 feet; but if such a penetration cannot be obtained without great depth of pile-driving it may pay to use more piles. (See Fig. 55.) Whenever a trestle is less than 15 feet high, framed bents may be dispensed with, and the piles left driven up to the bottom of the caps on which the stringers rest, in which case the outer piles are driven to a slight batter, and then pulled in, as the cap is drifted on, to a total batter of two or three inches per foot, or if the bent is only five or six feet high the piles may be all driven vertical; in either case, the centre piles are five feet apart and directly under each rail; usually a pair of × or sway-braces is bolted onto each bent, but no longitudinal braces are necessary. It is not good practice to build these pile trestles over 15 feet high unless for temporary work, as the vibration from traffic loosens the piles, and the rot at the ground surface is rather rapid and wasteful of material cut off, in case of renewals.

(3) *Mud Sills or Bank Sills.*—These consist of six or eight short cross-sills under the main sill of each bent, the usual dimensions are 8x12 inches by 5 feet long laid on flat, unboxed, which facilitates shimming by means of planks or boards under the main sills, and the bents will not get out of plumb if longitudinal braces are used. (See Fig. 56.) Other special foundations are:—Cribwork filled with stone where there is a current of water, a grillage or floor of timber in case of soft submerged ground, and holes cut in the rock, carrying the ends of the posts without any sill on steep solid rock side hill.

(*b*) *The founding of end bents.*—This is generally a difficult problem, as the freshly made embankments at each end of the trestle settle rapidly. Fig. 56 shows the three methods in ordinary use. Of these (*A*) is undoubtedly the best, but most expensive, as pile driving on sloping banks costs considerable; such piling should be done after allowing the bank to settle as much as possible, and the piles should be well driven into the solid ground to prevent them being shoved out of place longitudinally. (*B*) This method is pernicious, the embankment always contorts the trestle, no matter how well braced, the posts rot off at the ground surface, and it is also expensive and often delays the construction of the embankment; it has little to recommend it, unless the whole trestle is to be soon filled in. (*C*) This is seemingly a flimsy method, but is found very satisfactory in mild climates at least. Each

bent is supported on eight or ten mudsills, and as the bank settles a bridge gang surfaces and relines the trestle by shimming between the bents and bank-sills; after a few months, when the bank has become firm, very little attention will be required, and it is always convenient for repair or renewal, and nothing rots but the mudsills. It has also the especial merit of providing an elastic and gradual approach from the rigid trestle to the sinking fresh bank, which the first and second methods do not present. It is the cheapest method, and its only demerit is that it is affected by frost in the spring in cold climates.

Bent for narrow deck trestle with separate stories and deck-stringers.

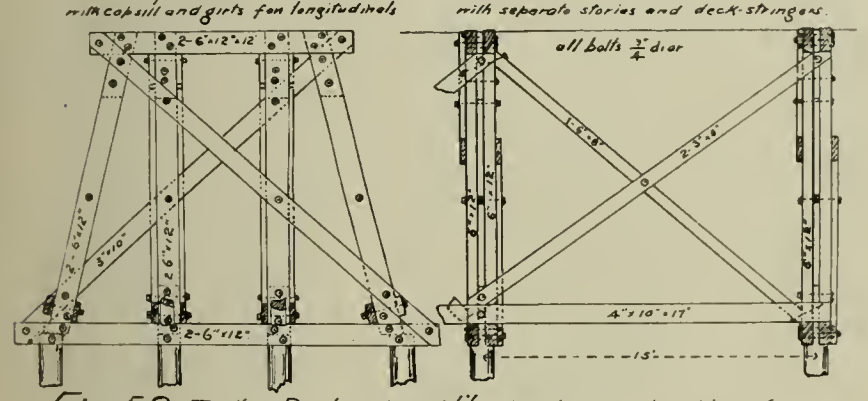

Fig. 58. Trestle - Bents using split cap sill and posts 2 pieces 6"x12"

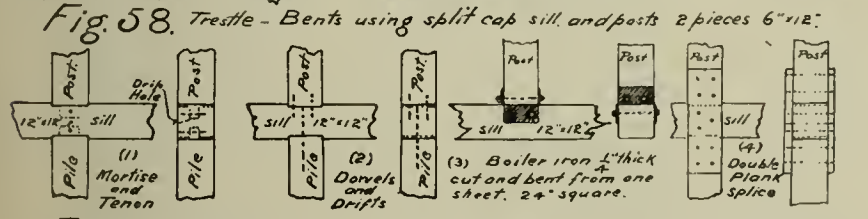

Fig 59. Methods of connecting posts with caps and sills.

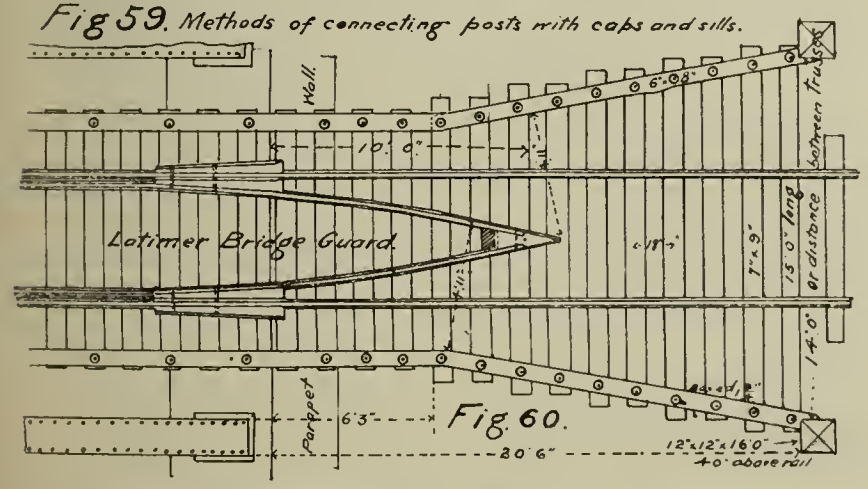

Fig. 60.

(*c*) *Trestle Bents and Systems.*—The ordinary styles of bents are with four posts, which are increased to six posts in very high trestles, each story or deck being braced by one or two pairs of cross or sway braces—the plumb posts being five feet apart, and batter posts sloping at from two to three inches per foot.

The longitudinal braces consist of cross braces and horizontal ties. The former are so grouped as to form towers and spans alternately, but the horizontal ties run the entire length of the structure. Speaking generally, low trestles on tangents need very little longitudinal bracing, while high ones on sharp curves need very much; between these two, the extent, disposition and sizes of such bracing will be a matter for the judgment of the designer, but all such braces should be bolted and not spiked, as vibration from trains will soon loosen the latter, and even bolts from the same cause and from shrinkage of timber need to have their nuts tightened two or three times before the rust locks them into place. Sway braces may, however, be partially bolted and partially spiked with pressed spikes.

The posts, caps and sills are usually of solid timbers 10 inches by 10 inches, 10 inches by 12 inches or 12 inches by 12 inches in section, the latter being most common. (See Fig. 57.) And such timbers make the best structures; but large timbers are often hard to obtain at reasonable prices, and in such cases, the style shown in Fig. 58 is found satisfactory and is easy to repair and renew. The split caps, sills and posts are usually 6 inches by 12 inches well bolted together; but the cost of such bolting, and danger of some of the bolts working loose are objections to the system. On the other hand, water is not so apt to lodge or rot where timbers are so narrow. An extension of this system is the "cluster bent" trestle, the posts being of four pieces of 6 inches by 6 inches, breaking joint and bolted to split caps and sill, with the cross braces acting also as separators. This style is advisable only in localities where timber is obtainable only in small dimensions, and of poor quality, its advantage being facility of repair; while the trestle itself is not so stable or durable as if made with larger timbers.

(*d*) *Joints and Fastenings.*—Fig. 59 shows the best methods in use. The advantage of mortise and tenon work is the easiness with which repairs can be effected, but it is a favorite lodging place for water and one of the first points to rot in a trestle—a drip hole partly obviates this; mortise and tenon work costs about $1 per M.B.M., more to frame than other methods shown. The drift bolt and dowel method is superior to the first one in rigidity, durability and easiness of erection, but is hard work to tear down, while the third method, although not in common use, appears to be a very sensible joint; the fourth method is for temporary work only, and is fastened with 6-inch pressed spike which would work loose very soon; it is an expensive and clumsy joint, but saves timber from mutilation for a second using. Probably the best combination is a tenon at the top of posts and 2 dowels 8 inches by 1 inch diameter at the bottom, such a system avoids rot and enables posts to be easily renewed and replaced.

(*e*) *High Trestles.*—When trestles are higher than 20 to 25 feet more than one story or deck will be needed (see Fig. 57), these may be either in separate bents locked by deck stringers, or they may be in a continuous bent in which the sill of one bent becomes the cap of the one below, etc.; in the former case the four lines of deck stringers, about 8 inches by 12 inches, overlap and are boxed onto the caps and sills and gained into them, giving a lock joint. The structure is very rigid, is simple of erection and easy to repair, but needs more material than the latter method, in which the longitudinal bracing consists of four lines of girts or wallings about 6 inches by 8 inches, which are butt-jointed and boxed about 3 inches on to the caps or posts and also bolted; this method saves one cap and some timber in the longitudinals also, and the upper and lower sway braces may be fastened by the same bolt at the cap-sill, but the trestle is a little harder to erect and much harder to repair, it is, however, on the whole probably the preferable method of the two.

(*f*) *Floor Systems of Trestles.*—The floor consists of stringers, ties and guard rails, and should be completed by adding some form of bridge guard like that shown on Fig. 60, by which trucks not too far off centre may be brought back to direction and probably placed again on the rails, or, at any rate, carried safely across the structure.

In Canada the wide-decked trestle, with two main

nests of stringers and two jack stringers supporting ties 12 feet to 14 feet long, is generally used on standard gauge roads, partly to give room for snowplows inside the guard rails and partly for additional safety; this is nowadays further supplemented by two lines of guard rails, of which the inner ones are faced with angle iron fastened by countersunk screws.

The sizes of guard rails and ties are shown in Figs. 61 to 65; but it is a growing feeling that ties cannot be spaced too close for safety to prevent bunching in case o derailment. They should not be more than 6 ins. apart clear at most and preferably 4 ins., and every fourth or fifth tie should be spiked to the stringers, and all boxed from $\frac{1}{2}$ in. to 1 in. on to them. There are some, however, who claim that if ties are kept spaced by the guard rail, and are boxed down on to the stringers, that any further fastening is unnecessary; ties should be of oak or some durable hardwood, which will hold track spikes.

Plate XVIII

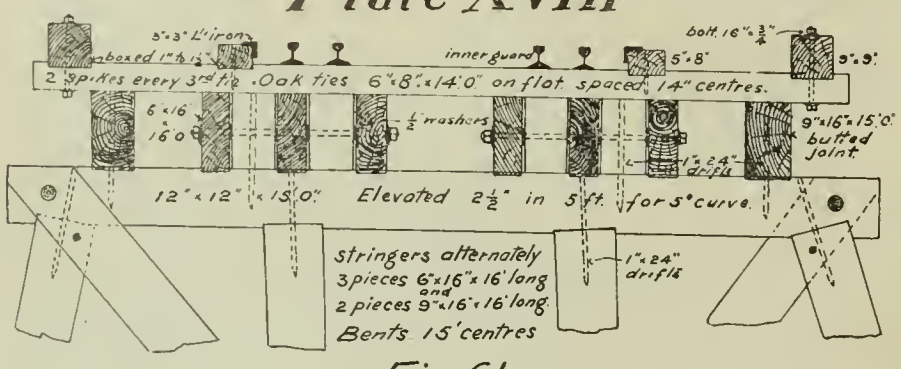

Fig. 61

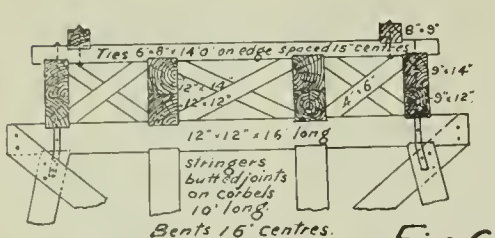

Fig. 62.

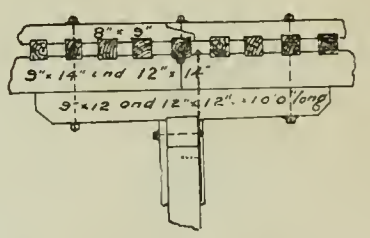

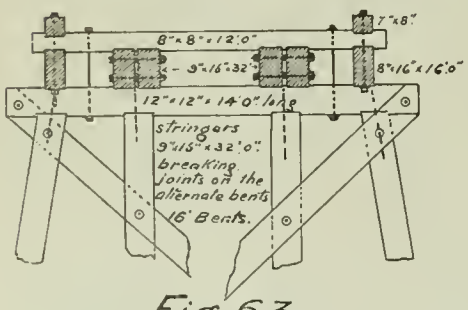

Fig. 63.

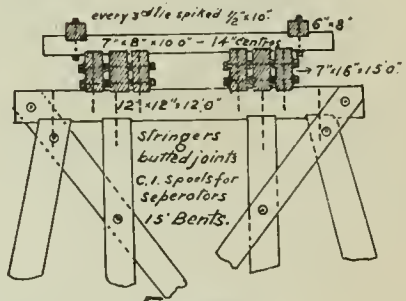

Fig. 64.

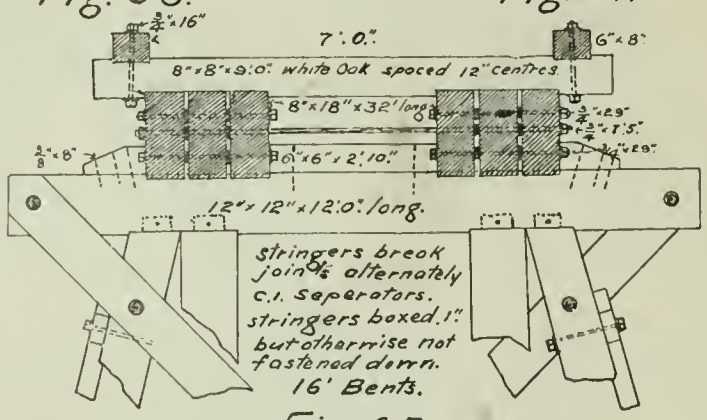

Fig. 65.

Cross Sections of Trestle Floors.

The guard rails should be of pine, or some durable wood that will not warp, and boxed down about 1½ inches on to the ties, so as to hold them apart, as well as to act as guard rails. They should be bolted on outer ones and spiked on inner ones to about every fifth tie. There are various styles of stringers; that shown on Fig. 61 is now almost standard for Canada. It consists of alternate groups of two and three stringers in two nests, one under each rail. These stringers are long enough to lap one foot and rest twelve inches on the caps, and are bolted together, but separated by cast washers to prevent rot, and each nest is drift bolted down to the caps. The outer or jack stringers carry very little of the load and are butt jointed, and also drift-bolted to the caps. The style shown in Fig. 62 is practically obsolete, being considered rather top heavy and demanding too heavy timbers; the corbels also give a very uncertain aid to the strength of the stringers. The style shown in Fig. 63 is used considerably in the United States. The stringers are 32 feet long, alternating with butt joints, and make a very stiff floor; but such large timbers are hard to obtain and harder to take in and out during renewals. One advantage, however, is that all ties will have the same boxings, while in Fig. 61, the length of boxing varies with each alternate bent—but the method of fastening the ties to the caps by long bolts is objectionable, such bolts will spring loose, and the heads would be cut off by the wheels of a derailed train. In the greater part of the United States, the narrow decked trestle, such as shown in Figs. 64 and 65 is very much used, there is an evident economy, the bents being narrower, the jack stringers omitted and only one guard rail, and that one close to the steel rails. It is claimed that such trestles with rerailing guards at each end, close spaced ties, and with an inside steel rail guard, are as safe as wider ones, and that a train which would derail so badly as to get outside the inner guards would leave the trestle anyway. Such floors are sometimes drift bolted down, or as in Fig. 65, held in place by a system of braces and rods—such a method having the advantage of facility of renewals.

(*g*) *Elevating Trestle Floors on Curves.* — This will amount to from a half-inch to five-eighths inch in five feet per degree of curve, and may be accomplished in various ways which are given in order of merit.

(1) Framing the bent with cap inclined to the required slope.

(2) Inserting an elevation or secondary cap on top of a level bent cap, and notching it down to suit the curve.

(3) Notching the main cap on light curves to receive the stringers.

(4) Placing blocks longitudinally under the ties and on top of the stringers.

(5) Sawing specially sloping ties.

(6) Placing strips or blocks under the steel rail but on top of the ties.

The sloping ties are, apparently desirable, but in renewals such a varied assortment is needed for trestles on various degrees of curve that it is an intolerable nuisance.

(*h*) The cost of trestle work is about as follows:

Cast-iron washers, etc.	2c. per lb.
Iron bolts, etc.	5c. per lb.
Framing and erection	$6 per M.B.M. (drift bolted).
" "	$7 " " (mortise and tenon).
Cost of timber	$17 to $27 per M.B.M.

A very ordinary price for timber now being $30 per M.B.M. in place, including iron; but in designing structures of this nature, by having due regard to the dimensions of timber which can be most readily obtained in any locality, the price may be held down, often somewhat lower than this, while sometimes a special price is put on stringers, which should be designed for the loads intended, and carefully inspected to see that they are up to the requirements, as they are the only members of the structure ever strained to their limit.

(*k*) *Quantities of Timber in Trestles.*—For very important and high structures, tables are of little value; but for ordinary use the following will give quite approximate quantities:—

TABLE XVI.

APPROXIMATE QUANTITY OF TIMBER IN TRESTLES PER 100 LINEAL FEET FOR VARIOUS HEIGHTS.

Narrow Deck, Timbers 10 in. x 10 in.			Lake Erie and Western.		Wide Deck, Timbers 12 in. x 12 in.	
Height.	F.B.M.		Height.	F.B.M.	Height.	F.B.M.

WILLIAM OGILVIE, THE CANADIAN EXPLORER.

William Ogilvie, Assistant Astronomer to the Dominion Government, was born in Ottawa, April 7th, 1846, when that city was known as Bytown, and before it had become the capital of Canada. In early life he had very slender opportunities of education. Apart from the fact that the family were not in affluent circumstances, his father, though a worthy and sturdy Presbyterian, had imbibed the idea that every boy should not merely be self-made, but self-made without school education. He had read in a favorite book of the Smiles' "Self Help" order, of a

The Lancefield Abell Co. Photo.
WILLIAM OGILVIE.

poor boy who could not afford a lamp at night, and studied with a borrowed book, standing under the light of a corner lamp, and he fancied that his son should go through the same process in order to achieve success in life. The mother, however, took a more sympathetic view of her son's difficulties and ambitions, and it was through her influence that the youth, when he made up his mind to become a surveyor, was given a chance to devote his whole time, for about three months, to home study to prepare himself for his future profession. He apprenticed himself to a local surveyor, and in spite of poor and insufficient text-books, and his service under a man who having obtained a surveyor's commission at a time when the standard of qualification was very low, had no literary instinct, and rather discouraged book learning in those under him, Mr. Ogilvie successfully passed his examination, and was commissioned as surveyor on the 12th July, 1869. From the proceeds of his own labors the young man was enabled to continue and extend his self-education, and the small local practice he obtained showed such intelligent and correct work that he attracted the notice of Surveyor-General Denis. At this time a number of long-standing disputes among landowners near Ottawa came to a head. There had been a good deal of vagueness in the law bearing on these cases, and the tangle was rendered worse by differences in the interpretation of the law between the officials of the Department and the Cabinet. Mr. Ogilvie, who had already been instrumental in settling a number of disputes between neighboring land owners for whom he had done professional work, was now called in by the Government, and his interpretation of the law was not only sustained by the Minister of Justice, but his plan for settling the disputes among the aggrieved farmers was accepted on both sides. In spite of jealousies and intrigues against him, the intelligence and sound judgment shown by Mr. Ogilvie in the cases in question resulted in his being called on in 1875 to do regular work for the Government, and in 1882 he began that career of exploration which has reflected honor on the Canadian nationality and placed his name in the very first rank of modern explorers. His first work was done in connecting the great Peace River region with the Dominion Land Survey system, which occupied the years 1882 and 1883. In 1884 he made an exploratory survey of the Athabasca and Peace rivers and in the following year he surveyed the Canadian Pacific Railway at British Columbia as a base line for the land surveys of the railway belt. In 1886 he was engaged on longitude work by electric telegraph. In the years 1887 and 1888 he made the exploratory survey of the Yukon, Porcupine and McKenzie Rivers which was to add so much to his fame by reason of the gold discoveries, of which, at that early date, he realized the value. In 1890 he was engaged in astronomical work in connection with the northern boundary of the Province of Quebec. In this expedition a canoe journey of 1,500 miles was made to James Bay and the East Main River, a great deal of valuable geographical information being added to our knowledge of these regions by Mr. Ogilvie, who at the same time carried on astronomical work by observations of the lunar culminations there. The importance of his geographical work in opening to the ken of the world new tracts of country of continental vastness became recognized in Great Britain as well as in Canada, and in the spring of 1891 he was awarded the Murchison medal of the Royal Geographical Society for having made the most important explorations in the world at that period; his services in surveying the Canadian North-West Territories being particularly mentioned in the award. In the same year he made an exploratory examination of the north-east portion of British Columbia, and in the following year was occupied with surveys around Prince Albert, Sask. In 1893 he was engaged on important work in connection with the delimitation of the international boundary line between Canada and Alaska, and this work, with the Taku expedition in Northern British Columbia in 1894-5, and the projection of the 141st meridian through the Yukon in 1896-7, gave him a wide knowledge, not only of the great alluvial gold fields of the Canadian Yukon, but of the conditions of life among the miners and traders, and a greater insight into the general resources of this great northern land than is possessed by any living man.

In these later expeditions, Mr. Ogilvie was called on to do all sorts of work for all sorts of people. If a miners'

dispute arose, he was appealed to as umpire; if any man was suffering wrong, he besought Ogilvie's aid in obtaining his rights. His decisions were accepted without dispute, and the secret of his influence throughou this time of gold madness was that his motives were above suspicion, his judgments always founded on common sense, and that he took no part in the universal grab for wealth. In all the wild excitement following the fabulous finds of gold, there was one man who kept his head and went on with his scientific work as if all the gold lying about him was accounted, like silver in the days of Solomon, of no more value than the stones of the street It is one of the admirable traits of this noble type of Canadian official that he has remained impregnable to the sinister suggestions of avarice though confronted with so many temptations; and one of the highest tributes paid him in this respect was by a New York paper, known for its anti-Canadian prejudices. A strong sidelight is thrown on this phase of his character by a British Columbia paper, which thus speaks of Mr. Ogilvie's relations to the miners.

"While admitting that the investment of three hundred dollars a few months ago in a grub stake for two men, taking in exchange a half interest in their claims, would have resulted in his being worth a million dollars to-day, Mr. Ogilvie modestly disclaimed any credit for refusing to invest, and it is almost certain that had he known at the time, beycnd any possibility of doubt, tha the investment of the $300 would have been as profitable as it has proved, his course of action would have been the same. 'I had to act up there as a sort of arbitrator, and I was not willing,' said he, 'to place myself in a position where my personal interests might have influenced my judgment." 'Regret it?' Mr. Ogilvie continued, 'no, not for a moment. As for money, I have plenty to satisfy me during my life, and I cannot take any away with me out of this world. As for my boys, they must work their way, as I have done, and they will be all the better men for it.'"

An interesting testimony to his perfect fairness to all the miners, irrespective of nationality, was recently given at San Francisco, when he was on his way home from the Yukon. A number of returned American miners sought him out and presented him with a valuable gold watch, in gratitude for his just administration of the affairs of he Klondyke.

A study of the accompanying portrait reveals a face indicative of great determination and administrative ability tempered with benevolence. We believe that Ogilvie is a greater explorer than H. M. Stanley. Without any of the harshness and arrogance that marked Stanley's methods, Ogilvie has, though not making any noise in a literary sense, accomplished greater work, and posterity will be brought to admit it.

In the twenty-two years during which he has been in the Government service he has traveled 75,000 miles by rail, 14,000 by steamer (mostly by the crude river crafts in use in the Canadian North-West), 8,500 by canoe, 9,500 on foot and 4,000 by cart or buckboard, making a total of 111,000 miles traversed on his official journeys. Difficulties such as Stanley and other travelers have depicted in dramatic colors have been passed over by Ogilvie without a word in his reports, and if the full story of his vast and lonely journey could be told it would make most valuable material for the future history of the great north land of Canada. It is very distasteful to him, however, to dwell on his own achievements, and it is only from his official reports, made as a matter of duty to the Government, that we can piece together some notion of his deeds. Once only did Mr. Ogilvie condescend to give a popular record of some of his work, and this was in the *Canadian Magazine*, for which he wrote a series of sketches under the heading of "Down the Yukon and up the McKenzie," and "In North-West Wilds," which appeared in 1893-4. The narrative of these remarkable travels is so simply told and yet so instructive and entertaining that all who have read them have wished for more. In one part of his first ketch he pauses in one of those days of 20 hours Arctic

WILLIAM OGILVIE, FROM PHOTOGRAPH TAKEN ABOUT 1889.

darkness to reflect "more than 2,500 miles were still lying between us and the nearest railway station, nearly all of which had to be got over on foot or by paddle"—a simple statement, but how eloquent of trial adventure, and enduring patience! In his sketch of the exploration of the great Mackenzie basin, he gives us a picture of daily life at Fort Nelson. One of the incidents is best told in his own words:

"There were two very old Indian women living at the Fort on such food as they got from the (Hudson Bay) Company's employees. One was totally blind, and the other nearly so. A half-witted Indian boy cut their wood and attended to their wants, and by way of compensation they shared their food with him. No one knew their age, but they had lived a long time for natives, as evidenced by their wrinkled faces, lustreless eyes, and toothless mouths. Their clothing was very scant and very dirty, their hut 'a thing of shreds and patches,' little better than none; their food was often scant, and their fire low. You fancy them utterly miserable, but they were not. I called on them daily with some food, a bit of tobacco, and a few lumps of sugar. This would put them into wonderful humor, especially the sugar. The blind one would hold her sugar in her hand, occasionally licking a lump, and exclaiming, 'Eh, Shugow,' (sugar) in a tone which bespoke complete ecstasy. The feast always wound up with a jocular discussion by these ancient dames as to which of them would secure me for their sweetheart. They invariably appealed to myself to decide between them, each meanwhile affecting all the airs of a pronounced flirt, displaying her charms with the most ludicrous poses, which convulsed me with laughter. The manner in which I parried these requests for a choice between them amused them highly, and who could refuse to brighten the lives of such poor old creatures with a little harmless pleasantry? Once the blind one, through the aid of the interpreter, told me her life story, how she had lost several husbands and all her children by death, had no friends alive that she knew of, and was waiting patiently

to join the lost ones in the Great Beyond. Her poor old wrinkled face and sightless eyes bespoke acute sorrow during the recital, especially when she expressed her desire to lay down the burden of her life. I have never elsewhere seen such squalid poverty accompanied by such childish cheerfulness."

This is an admirable bit of word painting, which, while it brings before us a vivid view of aboriginal life as it really is, to us reveals the tenderness and sympathy of the man.

One who knows Mr. Ogilvie intimately, gave the writer this estimate of his character: "He has a high sense of honor and strong judicial mind; careful practical generalship, enabling him to execute difficult undertakings and secure large results where most men would utterly fail; faithfulness to trust and scorn of anything underhand; energy and endurance, especially a capacity for protracted, constant labor. Add to these qualities his genuine good nature, his great knowledge of men and life, especially frontier life, and you have a man who is easily first among Canadian explorers, and I believe that only his modesty and disinclination to be 'boomed' has kept him from world-wide fame."

SILVER IN THE OTTAWA VALLEY.*

On Calumet Island, in the Ottawa River, some research work was done last year on the deposits of blende and galena, noted there for some years, and mining licenses were granted on several lots. On lots IV½, N.W. 10 and 11, the old Russell property, Charles B. Watts and others, of Toronto, have prospected from the end of last winter, with 10 to 15 men; some work was done on this mine by the first proprietors, who established the presence of important deposits of blende and galena, an assay of which gave zinc, 40 per cent.; lead, 12 per cent.; silver, 15 ounces per ton. The actual works have brought to light new indications, especially on lot 10 near the line of 11, where at a depth of 45 feet a deposit of blende several feet thick can be followed for a distance of 80 feet, from which 200 tons were extracted, 50 of which are still at the mine. It was on lot 11, near the line of 12, that a deposit of galena was worked two years ago.

Charles Meyer and others, of Belgium, under the name of the Grand Calumet Mining Co., control the properties IV½ S. 9 ½, S. 10 and 12, and have prospected since spring with six or seven men. On lot IV., 12, in the vicinity of the pocket of galena above mentioned, they sank a trial shaft, which was not more than fifteen feet down in September. The surface indications show a band carrying blende and numerous specks of galena. The same company has also prospected on lots 9 and 10, where some blende was found. On 10, galena in fine grains is found in the diorite. I understand that if the prospects are satisfactory this company will arrange for the regular working of this mine, and will establish concentration works. It intends to work this winter with steam engines and drills. On the central part of lot IV., 9, Colin Campbell has cleared away the surface and laid bare a remarkable exposure of solid blende, with a width of 40 feet by 12. It is probable that this ore body has greater extension, as the rock has only been laid bare on this part, and the walls are not visible. In the southeast part of the same deposit there is also a fine indication of galena, of which a sample, taken by J. Obalski, and assayed, gave 103.82 ounces of silver and strong traces of gold, the whole representing $60 worth of precious metals. On lot 8 of the same range he also prospected and found indications of blende disseminated in the quartzite. He has worked since this summer with four men only.

The southern part of Calumet Island where these deposits are found, belongs to a strip of rock called the Upper Laurentian by the Geological Survey; the northern part is Laurentian. A mineral band seems to exist there, accompanying an eruption of diorite running in a N.N.W. direction, as shown by the croppings and rusty rocks, and by the few prospects above mentioned. The width of this band does not seem to be less than 200 to 300 feet, and it is claimed that indications have been found between lots IV, 8, and VII, 27, where the seam ores have been noted, thus giving a course of about four miles. The ore body is of blende, slightly mixed with galena, and carrying a percentage of silver to the extent of about 15 ounces to the ton. Occasionally, the galena occurs alone, as on lots IV, 8, 11, when its proportion of silver rises to 146 ounces per ton, according to assays which I caused to be made, and even more according to other assays; small threads of native silver are also found. It is impossible to say to what depths these deposits extend, but it is possible that the galena grows more abundant, when they would become profitable to work. The shipping points are at Clark Station and at Campbell Bay, on the Pontiac and Pacific Junction Railway, at six or eight miles from the mines. The ground is not very rough, is partly occupied by farmers and supplied with good roads. The Government still owns the mining rights of a portion of this territory, as well as the rights everywhere to the precious metals.

* Extracted from the report of J. Obalski, C.E., to the Commissioner of Colonization and Mines of the Province of Quebec.

THE MOTOR CAR INDUSTRY.

The interview with Dr. Doolittle, which was published in the January issue of the ENGINEER, gives a very valuable outline of the present condition of the motor industry in Britain. None of the points he touched upon were elaborated, as the subject is such a many-sided one that it would require too much space. One criticism he made, however—namely, the exploitation of the industry by professional promoters for revenue purposes only—deserves fuller mention.

The Great Horseless Carriage Company, one of the off-shoots of the British Motor Syndicate, has been the victim of the most malign manipulation by promoters, and as a result its affairs are in a tangle. It is difficult to understand how level-headed Englishmen could have been wheedled into investing their money in a concern which had no business basis, the agreement upon which the company was formed having been so worded that it had no right to new patents issued since May, 1896. This means that, with their charter powers, the company must make carriages only from old patents that have been superseded; that it cannot make Daimler motors nor De Dion motors—these two being the most popular at the present time in Britain; nor can it make any cycle motors whatever. It is doubtful whether it can make a motor carriage to-day that would sell. In the course of litigation it has appeared that H. J. Lawson was the promoter and the sole acting director of the Great Horseless Carriage Company, and he had virtually also control over the British Motor Syndicate.

A committee of the Great Horseless Carriage shareholders has been formed to consider plans for the future of the company. Their report is lengthy and intricate, and need not be followed, except so far as it touches the main point dealt with in our interview in reference to the position of the motor car industry. For the purpose

of enquiring into the future of the industry some members of the committee went to Paris, where (never having been under government restrictions) the industry was making progress at the time prior to the passing of the English Act in Nov., 1896. They went through several large factories, each employing some hundreds of hands, and in most cases with order books full for many months ahead, and preparations for many large motors to increase the output. The principal motors in use were the Daimler, manufactured for vehicles by Panhard-Levassor & Peugeot, and the De Dion for tricycles, in which latter much business will certainly be done. A little attachment to their tricycles to hold two people is just out and becoming popular. It is also said that motor traction is being adapted to the French navy, postal service and army. The members of the committee returned quite satisfied with the progress and future of the industry in France. A visit was then paid to Coventry, where the Daimler Co. is now turning out several motors weekly; the Beeston Cycle Co. are making the De Dion tricycles, and the Humber Co. is starting with a regular output. Electric cabs are running satisfactorily in London, and a mail motor van is now undergoing long distance tests. In Scotland a line of motor cabs at Hamilton is working successfully, another at Blackpool, England, and cars are now under construction for two other lines to be opened in Scotland. There is of course a great deal of prejudice to contend with, but notwithstanding this the facts showed to the committee's satisfaction that the industry has come to stay; and the committee expresses the conviction that so soon as motor vehicles with all the latest improvements are turned out in quantity from the regular patents to enable them to be put on the market at reasonable prices, a motor manufacturing company will pay.

For The Canadian Engineer.

DISPOSAL OF TOWNS' REFUSE.

BY W. M. WATSON.

(Continued from last issue.)

At Liverpool, Eng., the refuse destructors are of the Manlove, Alliott & Fryers slow combustion type, divided into cells (as the furnaces are called in England) about $2\frac{1}{2}$ feet wide and 5 feet from front to rear. The refuse, which is of a very objectionable and filthy kind, is fed from the top, through holes at the rear end of furnace; the smoke and fumes from the fire are drawn off at the same place and pass over the damp, green refuse before entering the flues, for the purpose of drying the rubbish prior to arriving at the fire grate to be burnt. Only natural draught is applied by using a long chimney, and the temperature of the fires seldom exceeds 700° Fahr. On this ground the gases and fumes drawn off the fires must be cremated by passing them through a high temperature furnace, called a Jones' cremator, before being allowed to pass up the chimney to be discharged into the atmosphere. The weight of refuse, or garbage, which consists of mixed night soil, ashes, sweepings from paved streets, and house garbage, is reduced by 67 per cent. by the process of burning, yet the residue of clinker and ashes is not burnt sufficiently hard, and, therefore, of small value for ballast, etc. They have the same type of furnaces at Birkenhead, but have so altered the designs of the smoke flues that in place of being discharged at the rear end and the heat passing over the wet rubbish to assist in drying it, preparatory to being placed on the furnace, the fumes and gases are drawn out at the front near the clinkering door, with the object of compelling the fumes cast off by the roasting refuse to pass over the body of fire on its way to the collecting flues. This method partly consumes the poisonous gases. At Salford they also use the Manlove & Co. type, which they have so altered that they have increased the daily consumption of refuse by making a slight alteration in the feeding holes, and constructing their flues in a way that the flames and gases are collected and pass out at the centre of each cell or furnace, in place of being discharged at the rear or at the front end, as before explained. This method is stated by visitors and experts to be the most perfect low temperature, slow combustion furnace, working by natural draughts. But a great many of these furnaces are being made into high temperature furnaces of over 2,000° F., by applying forced draughts. Sometimes fans are used, but raw air is not the draught suited to burn rubbish, because the dry air forces part of the foul fumes forward past both the fire and combustion chambers, unburnt. When a mixed steam and air blower is used, the steam attracts and absorbs the poisonous fumes, and together with the heat of the furnace, destroys or purifies them, so that the gases can be freely discharged into the atmosphere without the aid of a fuel-burning cremator or a tall chimney.

By the slow combustion process, only seven tons can be burnt in 24 hours. When a strong forced draught is properly introduced with a few detail alterations, as much as 15 tons can be burnt in the same space of time, making a harder and better burnt clinker and ash, and reducing the weight of the residuum to about 25 per cent., while the low temperature process can only reduce it to 33 per cent. At the rural village of Withington, the destructors were built from their own surveyor's designs. They consist of six low temperature furnaces, a fume cremator, a chimney 150 feet high, engine, boiler, dynamo, motor mill' etc., the total cost being £3,400. At the bottom of the chimney stack double wire screens are fixed to prevent anything unburnt from being drawn up the chimney. At Cambridge they use Manlove's Destructors, and use the heat for generating steam that creates power sufficient to pump the town's sewage. They also have a dual system at Baildon. Their refuse destructor is of a slow combustion type, with a low temperature, so that the rubbish, ashes, night soil and garbage are only carbonized *and not burnt to an ash.* Each cell or furnace place is fed in at the rear of the fire bars, the rubbish sliding down an inclined plate from the tipping floor. The air or smoke pipes are carefully and mechanically adjusted in a way that the fire is almost smokeless, because loss of smoke means loss of carbon. They are fixed in the side walls near the front door, drawing sufficient to give the furnaces the right quantity of air to allow the refuse to carbonize, but not to burn sufficiently to make smoke. The residuum is a mixture of soft clinker, cinders and powdered charcoal, which are carbonized in this way under a patent for the purpose of using the residuum for a filtrate to purify the town's sewage, it being found to be the most suitable material. In this way Baildon cleans and purifies the town's sewage with the foul refuse, thus using one public nuisance to destroy another.

The Bradford corporation has the Manlove, Alliott & Co. furnaces, improved and altered to come up to the times, and as I before pointed out in the January issue, the fumes from the drying refuses pass over the fire, up through holes in the firebrick screen (which forms the arch over the fire) near the door, then through its own combustion chambers, passing along to the large collecting vault, thence through the flues to the steam boilers, from them through the economizers, afterwards finally passing out at the chimney. The combustion chambers and large vault

being always near a white heat, the gases from all the twenty furnaces get reburnt and well mixed together, causing a high temperature and an increase in the number of units of heat useful for steam raising purposes, proving that plenty of good brick work, well put together, scientifically arranged, so that it divides the particles and mixes the gases, expanding and increasing them, is a good investment because it largely assists in extracting all the injurious fumes from the discharged gases and nearly doubles the number of units of heat used for raising steam.

(*To be continued.*)

CANADA HOLDS HER OWN.

The question of how best to reach the golden North has been decided by the Dominion Government, after consideration of the reports of engineers W. T. Jennings, Wm. Ogilvie, and others. The press of the United States has been most active in suggesting methods by which Canadians might be harrassed on their way to mine Canadian gold on Canadian lands. It has been found possible to make entry through United States ports troublesome and expensive—the people of Seattle and other western towns have thought that in this way they could capture the outfitting trade. The natural result has followed, and the Dominion Government has chartered a railway which will give us an all Canadian route to the Yukon country. Reference to the accompanying map of Alaska and the Yukon territory shows us the stretch of 150 miles between Telegraph Creek and Teslin Lake, which the McKenzie and Mann railway is to cover. The mouth of the Stikine River, as it is now officially known, is in the United States, but the free and uninterrupted navigation of the river, and every other on the coast, is guaranteed to British subjects by treaty.

metals produced from the lands alienated to the company, as compared with 10 per cent. imposed upon ordinary placer mining. The contractors are not to receive a cash subsidy, but, on the other hand, are required to put up a deposit of a quarter of a million of dollars as a guarantee for the execution of their contracts. No portion of the beds or of the banks for 25 feet on each side of high-water mark shall pass to the contractors under any selection of lands to be made under the agreement. The shores and all landing places, few and far between in that rugged, rock-ribbed country, and therefore very valuable, are withheld, and the free rights of passage and use along all navigable or floatable streams may not be impeded or obstructed by the company, and are absolutely reserved to the people. In case the contractors divert any stream from its natural channel, they must provide an equally convenient navigable or floatable channel in lieu. All mining claims held and recorded by free miners within any block of land selected by the contractors, shall be excepted from the grant, and shall not pass to the contractors. The tolls to be collected on the railway between Stikine River and

The details of the agreement between the Dominion Government and McKenzie & Mann, as given to the public, is summarized below. The agreement provides for the construction of a railway from the Stikine River, in British Columbia, near the mouth of Telegraph Creek, Glenora, or the mouth of the Clear Water River, northward to Teslin Lake, a distance of about 150 miles, thus giving connection with the Lewis or Yukon River, and an all-Canadian rail and steamboat route from a port on the Pacific coast to Dawson City. This road must be completed and in operation by September 1 next The contractors must also construct a practical sleigh road from the mouth of the Stikine River to Teslin Lake, and provide suitable shelters and stopping places for travelers at intervals of not more than 25 miles along this road, and the road and shelters must be available for use not later than six weeks from now. The contractors must also provide steamboat transport of freight and passengers between Teslin Lake and Dawson City. The Government proposes to grant 25,000 acres a mile of mineral lands, or 3,750,000 acres in all, to the contractors. The lands shall be selected from the Klondyke provisional district, and from that part of the North-West Territories lying west of the Mackenzie River and Liard River and north of the 60th parallel of latitude But it is provided that all arable land shall be reserved. It is also provided that in determining the selection of lands for the contractors, each alternate block shall be reserved for the Government. In addition a royalty of 1 per cent. will be laid upon all the precious

Teslin Lake will be first fixed by the Governor-General-in-Council, and, as so fixed, shall not be liable to reduction for four years. They shall then be reduced by 25 per cent., and after the road has been operated for seven years there shall be a reduction of 25 per cent. on the tolls as previously reduced, and after the road has been ten years in operation the tolls shall be subject to the general railway law of Canada in that behalf. The lands granted shall be free from taxation for ten years, except municipal taxation by an incorporated city, town or village within the Klondyke provisional district. When any ten continuous miles of the railway have been completed, the contractors may select 92,168 acres, or two blocks of land, and these blocks shall thereupon be reserved from sale or location, or free miners' claims, and on completion, from time to time, of any other ten miles, the contractors shall have the right to select two additional blocks, and on the completion of the railway, the blocks so reserved shall be granted to the contractors, with the exception of any existing free miners' claims, which shall be held inviolate. For five years from Sept. 1st, 1898, no line of railway shall be authorized by Parliament to be constructed from Lynn Canal, or from any point near the international boundary between Canada and Alaska into the Yukon, nor shall any aid in money or land be granted to any other contractors for this purpose. Moreover, during ten years from Sept. 1st, 1898, the contractors shall be given the preference in any aid the Government may see fit to grant towards the building of a line of railway from the Stikine River to an ocean port in British Columbia, provided they are willing to undertake the construction within a reasonable time.

MACHINES.*

A machine is an instrument by means of which a force applied a one point is able to exert at some other point a force differing in direction and intensity. It has been usual in treating of simple machines to call the force applied power; but the word power is now in use with an entirely different meaning, and so we shall accordingly speak of the applied force as the effort. The force exerted, or effective resistance overcome is usually called the weight. This resistance may be the earth's attraction, as in raising a heavy body, or it may be the molecular attractions between the particles of a body, as in stamping metal or dividing wood, or it may be friction, as in drawing a heavy body along a rough road. Besides the effective resistance, the effort is employed in overcoming the internal resistances, chiefly due to friction between the different parts of the machine. The effort may be just sufficient to overcome these two kinds of resistance, or it may be excess of what is necessary, or it may be too small. If just sufficient, the machine once in motion will remain uniformly so, or if it be at rest, it will be on the point of moving, and the force applied or effort will be in equilibrium with the effective and internal resistances. If the effort be in excess, the machine will be set in motion and continue to move with an accelerated motion. If the effort be too small, it will not be able to move the machine, and if the machine be already in motion it will gradually come to rest. When the effort is just sufficient to overcome the resistance, the ratio of the resistance to the effort is called the modulus of the machine. In this case, it is evident from the law of conservation of energy, that the work done by the effort has its equivalent in the work done against the effective resistance to be overcome, and against the resistance due to the friction between the parts. This is the general law of machines in motion or in equilibrium.

The ratio of the effective resistance, which we call simply resistance to the effort, is equal to the ratio between the distance through which the effort acts, and the distance through which the resistance is overcome in the same time, or, in other words, is equal to the velocities of the points of application of the effort and resistance; or, if we take equal distances and uniform motion, we see that what is gained in force is lost in time.

Simple machines, sometimes called the mechanical powers, may be considered under three heads: 1. A solid body movable around a fixed point; 2. A flexible string; 3. A hard inclined surface. Under No. 1 come machines acting on a lever, and wheel and axle, such as the crowbar, etc. In this case the difference between the power and fulcrum is greater than the difference between the fulcrum and weight. In the case of the wheelbarrow, row boat, etc., the power is at one end, the fulcrum at the other, and the weight between the two. In the human arm the weight is at one end, the fulcrum at the other, and the power between. Under No. 2 come pulleys. In the case of the single pulley the power exerted must be equal to the weight; it simply changes the direction of the force. Where more than one pulley is used, as in one block, the first one would support the whole weight, which we will say is 100 lbs.; the second pulley would support one-half of what is supported by the first, or 50 lbs.; the third would hold or support one-half of what is supported by the second, or 25 lbs. The force, therefore, required to lift the 100 lbs. would only be equal to 25 lbs., but, as it has been already said, what is gained in force is lost in time. No. 3, inclined surfaces, including the wedge and screw. To take a weight up an inclined plane, the weight and height must be equal to the power and length. In the screw the power and circumference equals the weight and distance between threads.

* A paper read before the Hamilton Branch, C.A.S.E., by Jas. Gill, teacher of Physics, in the Normal College and Collegiate Institute, Hamilton, Ont.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the metal imports from Great Britain during December, 1896, 1897, and the twelve months to December, 1896-1897.

	Month of Dec.,		Twelve months ending Dec.,	
	1896.	1897.	1896.	1897.
Hardware and cutlery	£3,557	£4,327	£62,382	£68,144
Pig iron	60	225	28,026	9,434
Bar, etc.	386	263	15,540	8,892
Railroad	36	..	174,470	45,789
Hoops, sheets, etc.	2,473	112	49,435	77,935
Galvanized sheets	1 606	5,185	56,013	57,955
Tin plates	31,217	7,149	184,043	224,570
Cast, wrought, etc., iron	1,528	4,625	49,286	36,604
Old (for re-manufacture)	..	170	15,758	7,854
Steel	3,001	3,946	88,394	55,902
Lead	1,777	978	18,128	28,370
Tin, unwrought	1,152	3,356	21,103	20,725
Cement	8	2,701	32,731	22,498

TESTS OF CAST-IRON COLUMNS.*

We present herewith a report of the tests of full-sized cast-iron columns recently conducted by the Department of Buildings of New York city at the works of the Phœnix Bridge Co., Phœnixville, Pa., under the direction of W. W. Ewing, of the department. The tests began on Dec. 15th at 1 p.m., and were finished on December 21st. The machine used was the testing machine at the Phœnix works. To ensure the accuracy of the tests, the Building Department arranged a comparison of the Phœnix machine with the famous Emery machine in the United States Arsenal at Watertown, Mass. On December 30-31, 1896, a series of compression tests was made at Watertown upon a soft steel Phœnix column built by the Phœnix Iron Company especially for these tests. It was made of eight segments riveted together, forming a round column 21 feet long, inside diameter 14⅝ inches, thickness of metal 1⅛ inches, area of section 75 3 square inches, total weight of 5,485 lbs. The calculated safe load was 530 tons. The column was shipped to Watertown Arsenal and carefully tested in the Government machine shops at that place. Marks were made 26 inches from the ends, that is, 200 inches between marks, and a form of roller extensometer reading to 1-10,000 inches, was employed, to take all measurements. In applying the load constant increments were used. Certain additional loads were applied, corresponding with those to be applied later in the Phœnix machine. The column was then returned to Phœnixville, and the tests repeated in the Phœnix machine. The conditions were reproduced as nearly as possible; the same series of readings were taken, using the same extensometer. The results of the two tests are shown in Tables I. and II.

The gauge used to calibrate the Phœnix machine was a mercury column instrument, manufactured by Thomas Shaw, of Philadelphia, Pa., and numbered 5,447, was calibrated to read in pounds per square inch, and ranged from 0 to 220 lbs. The pressure used in the cylinder of the hydraulic testing machine is received on a diaphragm and transmitted to the lower end of the double-headed piston, whose upper end, of much greater diameter, is surmounted by another diaphragm, above which is a reservoir of mercury, and a mercury column of small bore. The actual tests were made with a higher reading mercury column which was compared with instrument No. 5,447 at the time of the tests, and afterwards by the maker of both instruments.

From the figures thus obtained the following computation of the calibration of the Phœnix testing machine was made and included in Mr. Ewing's report:

Let P = unit load in Watertown machine.
l = compression in ins. due to P.
P' = unit load in Phœnix machine.
l' = compression in ins. due P'.
P = 1 lb., l = .0000000891, and l' = .0002432916.
If $P : P' = 1 : l'$

then $\frac{P}{P'} = \frac{l}{l'}$, and $P' = \frac{P\,l'}{l}$

$$P' = \frac{.0002432916}{.0000000891} = 2{,}730.54 \text{ lbs.}$$

* Reprinted from the *Engineering News*.

This figure indicates that each unit on the gauge must be multiplied by 2,730, to obtain the pressure exerted in lbs.

TABLE II.

COMPRESSION TESTS OF CAST-IRON COLUMNS MADE FOR THE DEPARTMENT OF BUILDINGS, NEW YORK CITY, IN 1896, BY GUS. C. HENNING, M. AM. SOC. M. E.

No.	Length.	Outside diameter, inches.	Thickness — Maximum.	Thickness — Minimum.	Thickness — Average.	Breaking load, actual gauge-reading, lbs.	Sectional area, sq. inches.	Breaking load per sq. in. lbs.	*Corrected breaking load per sq. inch.
1	147¾ inches.	8	13-16	⅝	¾	520,000	17 08	30,400	25,840
2	150 "	9	1⅛	¾	1	630,000	25 14	25,100	21,340
3	162 "	12	1	1	1	1,250,000	34·55	36,200	30,770
4	159¾ "	14	1⅛	¾	1	1,226,000	39.84	30,700	26,100

* The figures in this column are obtained by deducting 15 per cent. from those in the preceding column, for friction of the machine.

We come now to consider the results of the breaking tests of the cast iron columns. Ten columns were tested, six of them being 15 feet 10¼ inches long, 15 inches diameter, and from 1 to 1 3-16 inches thick; two were 13 feet 4 inches long, 8 inches diameter, and two were 10 feet long and 6 inches diameter. A condensed table of results, Table III., is given herewith, the last two columns of which are from our own calculations, and are not given in the Building Department report, which gives only the actual data obtained without drawing any conclusions.

From the observations reported by Mr. Ewing, we quote as follows:

Column 1—Column suddenly broke under a total load of 1,356,000 lbs. into 10 pieces; the fractured surface began about 3 feet 4 inches (average) from the bottom.

The quality of metal was medium grain; foundry dirt and blowholes were quite numerous; in one place the foundry dirt extended half way through the metal; in another place, there was a thin layer of foundry dirt and honey-comb midway between the inner and outer surfaces; between this layer and the two surfaces, the metal was perfectly sound: this layer of foundry dirt contributed to the weakness of the column, as was evident from an inspection of the fractured surface.

The column sheared at an angle of about 30° with an element of the surface, and about 45° with a normal to the surface, inside of the layer of foundry dirt, above referred to only. This layer of foundry dirt extended about 6 inches around (circumference) on column. At another fractured surface where no defects occurred, the metal sheared along a spiral course about 45° with an element of the surface, and at an angle of 45° with a normal to the surface; this surface was about 15 inches long.

Column 2.—The column crushed near the lower end, many of the pieces being quite small; the bottom flange was left intact, the fractured surface beginning at the top of the flange or 1¾ inches from the faced end of the column and extending around the shaft in an irregular manner, reaching 5 inches away from bottom flange in one place

The shaft of the column above the fractured portion was found to be permanently sprung ½-inch in a distance of 9 feet 4 inches along shaft. The quality of metal at bottom of column, where fracture occurred, was medium grain and quite uniform in grain. Considerable quantities of foundry dirt was found at fractured surfaces and where the column crushed into small pieces, the foundry dirt extended all the way through in many spots.

The shaft sheared in several places at an angle of about 45° to the elements of the surface of the column parallel with its axis, the fractured surface following a sort of spiral path around the shaft. The metal at the same time sheared through at an angle of from 30° to 45°, with a normal to the surface of column.

Column B 2.—The fractured portion of column was below the centre, beginning 3 feet 9 inches from bottom and 6 feet 6 inches from top of column. Quality of metal rather course, but quite uniform. Flaws occurred in spots, but not bad. There was evidence of shear at 45°, the same as in preceding columns.

Column B 4.—The quality of metal was rather coarse in centre of shell, and somewhat finer toward the surfaces. Cinders and slag in considerable quantity, two bad spots nearly opposite at bottom of column where metal was poor; one of these was 5 inches long on outside (around column) and extending about half way through the metal On the opposite side the defective portion was 4 inches wide on inside, and extended for one third to two-thirds the way through the metal. There were indications of shear at about 45°, similar to cases previously noted, at the bottom, where the column broke into

TABLE I.

RESULTS OF BREAKING TESTS OF CAST-IRON COLUMNS.

Column No.	Length.	Outside diameter.	Thickness — Maximum.	Thickness — Least.	Thickness — Average.	Location of break.	Breaking load, lbs.	Compression.	Character of metal at fracture.	Sectional area.	Breaking load per sq. in. of area. lbs.
I.	190¼ ins.	15 ins.	1	1	1	About 3 ft. 4 ins. from bottom.	1,356,000	.....	Medium grain; *a* blowholes and dirt.	43.98	30,830
II.	190¼ ins.	15 ins.	1 5-16	1	1⅛	Bet. 1 and 5 ins. from bottom.	1,330,000	.....	Medium grain: *b* fairly uniform, spots of dry dirt.	48.03	27,700
B 2.	190¼ ins.	15 ins.	1¼	1	1⅛	Bet. 3¾ feet from bottom and 6½ ft. from top.	1,198,000	2½ ins. bet. 150,000 and 1 108,000.	Coarse, but uni- *c* form; a few flaws.	48.03	24,900
B 4.	190¼ ins.	15⅛ ins.	1 7-32	1	1⅛	Betweeen bottom and one-third up from bottom.	1,246,000	2¼ ins, bet. 150,000 and 1,246,000.	Coarse in centre; *d* finer on outside; cinders and slag.	49.48	25,200
5.	190¼ ins.	15 ins.	1 11-16	1	1 11-64	At bottom flange.	1,632,000	2 5-16 ins. in 8 ft. 3 ins.	Fine grain and *e* uniform where no flaws occur'd.	50.84	32,100
6.	190¼ ins.	15 ins.	1¼	1⅛	1 3-16	No break; permanent set of 1 3-16 ins. in 8 feet.	Over 2,082,000	⅜-in. betw'n 232,000 and 1,108,000	No break. *f*	51.52	Over 40,400
XVI.	160 ins.	Bet. 8¼ and 7¾ ins.	1¼	⅝	1	Where chaplet was placed at middle and at ends.	651,000	.....	Metal g'd; me-*g* dium grain.	21.99	31,900
XVII.	160 ins.	8 ins.	1 3-32	1	1 3-64	At middle and ends.	612,800	.....	Fine grain, uni-*h* form, and free from flaws.	22.87	26,800
7.	120 ins.	6 1-16 ins.	1 5-32	1⅛	1 9-64	At middle and each end.	400,000	.....	Good even grain, *i* no flaws.	17.64	22,700
8.	120 ins.	6 3-32 ins.	1⅛	1 1-16	1 7-64	At middle and each end.	455,200	.....	Fine grain, uni-*j* form, and free from flaws.	17.37	26,300

REMARKS.—*a*. One place, foundry dirt extended half way through; another place, foundry dirt and honeycomb between inner and outer surface.

b. At a pressure of 1,302,000 a slip of some kind occurred, which dropped the pressure to 1,275,000; again run up until break occurred. Upper portion sprung ½-inch in 9 feet 4 inches.

c. At 1,108,000 column sprung badly; movement recorded under compression.

d. Bad spots, cinder pockets and blowholes near middle of column; small cracks in necking near top; column given a permanent set.

e. Flaws and foundry dirt at point of break; load was carried as high as 1,803,000. The dummy head against which column rested was found broken after the test; this may have had something to to do with character of break.

f. Pressure run up to 1,108,000 and released. It was again run up to 2,082,000, released and run up to 2,033,000. Column could not be broken; capacity machine reached.

g. At time of breaking, column had a vertical deflection of 3 9-16 inches and a horizontal deflection of 1⅛ inches; fracture seemed due to flexure.

h. Vertical deflection, 4¼ inches; horizontal, 7-32 inches.

i. Vertical deflection, 3¼ inches; horizontal deflection, 1 11-32 inches.

j. Vertical deflection, 3 inches; horizontal deflection, ⅞ inch.

small pieces, The total number of pieces was 15. The fractured surface revealed many cinder pocket and blowholes near middle of column. Small cracks were observed in the necking near top of column.

Column 5.—Column broke into 14 pieces; all fractures occurred below the lower necking on column and broke through bottom flange. The permanent set in the shaft between the upper and lower necking was $2\frac{5}{16}$ ins. in 8 ft. 3 ins.; the upper part of the shaft above the necking remained perfectly straight after the test. Flaws were found in fractured surfaces near bottom, of foundry dirt. One bad flaw about 5 ins. wide and 4 ins. high (long) on outside, extending three-fifths of the way through. Quality of metal was rather fine grain and very uniform where no flaws occurred. Part of the shaft remained intact to end, and part of flange was left on. After the test, it was found that a dummy head against which the end of the column bore, was broken in such a way that the load on the column was eccentric after the head gave out; the nature of the fracture sustains this belief.

Column 6.—The test was discontinued when a load of 2,033,000 lbs. had been reached, the capacity of the machine having been reached. The permanent set of the column after it was removed from the testing machine was $\frac{3}{16}$-in. in a length of 8 feet 5 ins. The concave side, after the test, was about 90° from the joints of the flack, and undoubtedly was the top of the column as cast in the mold.

Column XVI.—One fracture occurred at a point where the chaplet for holding down the core was imbedded into the metal of the column. the metal outside of the chaplet was $\frac{7}{8}$-inch thick, and the chaplet 3-16-inch metal. The cast metal did not adhere to the chaplet. The column broke into six pieces (at middle and at each end). The fracture at the middle was nearly square off, and very near the exact middle point between the two ends. The fractures were about one foot from each end and irregular in outline. The metal was good, of medium grain. Wires were attached to the shaft of the column, 6 feet 6 inches from bottom, and ran perpendicular to the axis of the column, one horizontally and one vertically. These were carried to the outside of the building in which the tests were being made, and the actual vertical and horizontal deflections of the column were observed in conjunction with the corresponding loads. There was no evidence of shear at the fractured surfaces, as in the case of the larger columns. Failure seemed to result primarily from flexure.

Column XVII.—The column broke into eight pieces, the fractured points being at the middle and near each end. Quality of metal at fractured surfaces was fine grain, uniform and free from flaws.

Column 7 was broken into four pieces, the fractures being 3 inches to one side of the middle of the column and near each end. The quality of the metal was good, even medium grain, with no flaws.

Column 8.—The quality of metal was fine grain, uniform and free from flaws. The column broke into four pieces, fractures being at middle and near ends; broke off nearly square at each point; no signs of shear in metal.

Two of the 15-inch columns tested, Nos. B 2 and B 4, were taken from the Ireland Building, which it will be remembered, collapsed August 8th, 1895. The four remaining 15-inch columns were made from drawings prepared by the Department of buildings of New York city, and were as nearly as possible duplicates of the Ireland columns.

The columns marked I. and II. were made by the Jackson Iron Works, New York city, of their ordinary run of metal. They were cast while other columns were being cast, with no knowledge of their ultimate use. The two marked 5 and 6 were made by the Healy Iron Works, Brooklyn, N.Y., who were informed of what the columns were wanted for. The drawings for the 6-inch and 8-inch columns were also made by the department.

All the columns broken were, we understand, fair samples of the ast-iron column used in buildings in New York city, and regularly passed by the Building Department as coming within the provisions of the law.

The building law of the city of New York says:

"The strength of all columns and posts shall be computed according to Gordon's formulæ, and the crushing weights in pounds, to the square inch of section, for following materials, shall be taken as the co-efficient in said formulæ, namely: Cast-iron, 80,000. . . . The factors of safety shall be as one to four for all posts, columns and other vertical supports when of wrought-iron or rolled steel, and as one to five for other materials, subject to a compressive strain."

Applying Gordon's formula* with the co-efficient 80,000, as above required, in the numerator, and 400 (which is not given in the law, but is given in Haswell's Pocket Book, to which reference is made) in the denominator, we have

$$S = A \frac{80{,}000}{1 + \frac{l^2}{400\, d^2}}$$

* Mechanics' and Engineers' Pocket Book, Chas. H. Haswell, 1897, p. 768.

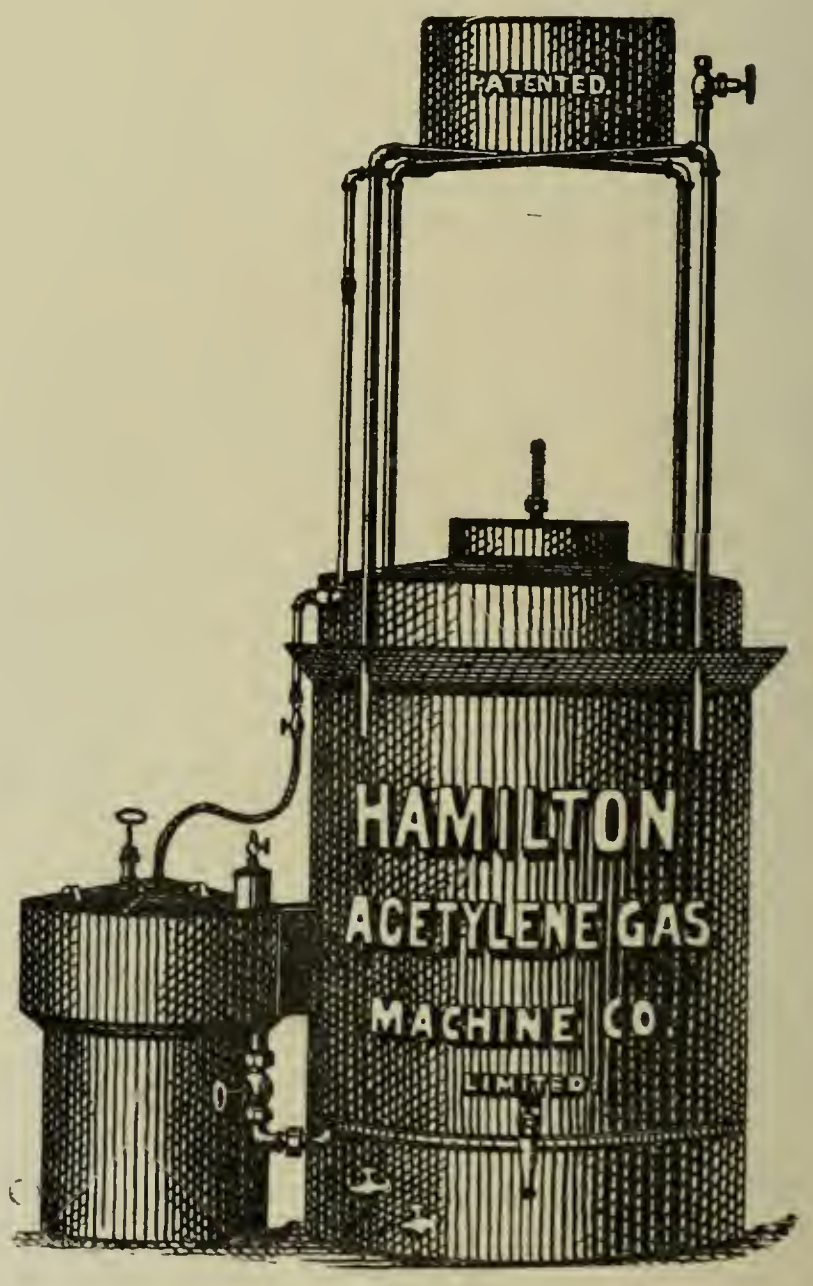
in which S is the breaking load, A = sectional area in sq. ins., l = length, and d = diameter of the column in inches.

For the 15-in. columns we have l = 190 ins., d = 15 ins., S = 57,143 A. For the 8-in. columns, l = 160 ins., d = 8 ins., S = 40,000 A. For the 6 in. columns, l = 120 ins., d = 6 ins., S = 40,000 A. That is, by the New York law, the 15-in. columns would be calculated to have a breaking strength of 57,143 lbs. per sq. in., while the actual tests show that their strength was only from 24,900 lbs. to something over 40,400 lbs. per sq. in. The 6 and 8-in. columns would be calculated to have a breaking strength of 40,000 lbs. per sq. in., while their actual breaking strength was only from 22,700 to 31,900 lbs. If such columns as these are loaded in buildings with the loads which the law allows, the factor of safety, instead of being 5, as required in the law, is actually in some cases more than 2. This is also borne out by the results obtained during similar tests conducted about a year ago by the Department of Buildings with full-sized cast-iron columns. The dimensions and results of these tests are given in Table IV. The values given in the column headed "Breaking load" are in round numbers, hence the breaking loads per square inch of area are correct to the hundreds as given.

A NEW ACETYLENE GAS GENERATOR.

The Hamilton Acetylene Gas Machine Co. having acquired the rights of a new acetylene gas generator invented in Welland, has established a factory at 228 King Street East, Hamilton, where it is now turning out large numbers of the machines, for which there is an active and growing demand.

A rough sketch of this machine is presented herewith. The water for feeding the carbide is taken into a tank above the gas holder, and this tank is kept full by means of a ball-cock attachment such as is used in a water closet tank. From here the water is fed to the car-



bide chamber shown to the left of the foot of the gas-holder. The holder is much the same in principle as a coal gas holder, and has the usual water-seal. As the gas is exhausted from the holder, a small bar which projects over the edge of the roof of the holder, catches the arm of a lever valve, and as it descends the valve is opened and the water starts to flow from the upper tank through a rubber pipe into the carbide chamber. The jet of water does not fall in one spot on the carbide, but is distributed over the material in a spray on all sides from a nozzle. When gas is thus generated by the water, the acetylene fills the holder, but when full the excess of pressure is relieved either by the top of the holder striking a spring valve and so

opening an outlet to the waste gas pipe which leads outside the building; or by an internal pipe, the lower end of which is lifted above the water-seal before the holder is full to excess. Two small cocks at the bottom of the holder let off the water that may gather from condensation; and when the carbide chamber needs re-charging a cock is turned in the gas supply pipe to prevent the gas from returning out of the holder. The carbide is held in the chamber by a wire cage in which receptacle it may be agitated by a shaker which can be operated by an outside handle.

The following are the special claims put forth for this machine by its manufacturers: (1) It is perfectly automatic in its action, and makes gas equal to the consumption only. This they claim above all other machines that are in the market. (2) It is not dependent upon the gas pressure to regulate the supply of water to the carbide, consequently the pressure upon all parts of the machine is at all times equal and does not exceed the amount necessary to supply the burners, viz, one and one-quarter ounces per square inch; it is therefore absolutely safe. (3) It mechanically regulates the quantity of water that is from time to time automatically brought in contact with the carbide, as the consumption requires, so that gas cannot be generated beyond the capacity of the machine. (4) The generator is so constructed that the carbide can be added and the ashes instantly removed without loss of gas, without shovelling any ashes, and without unscrewing any parts of the generator with a wrench or otherwise. All we have to do is to lift the cover off the generator and lift out the vessel and dump contents, then re-charge with carbide. Joints are all water joints. We challenge any other machine on these points. (5) A generator holding from 30 to 50 pounds of carbide will supply gas for a large dwelling house or store sufficient to last two or three weeks, and will require little, if any, attention.

The company is in possession of a number of very gratifying testimonials from users of the machines, and claims to have the cheapest machine in the market.

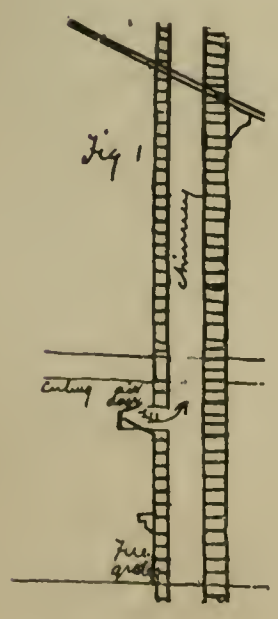
The president of the company is Dr. George S. Bingham, and the secretary, A. J. Seguin.

For The Canadian Engineer.

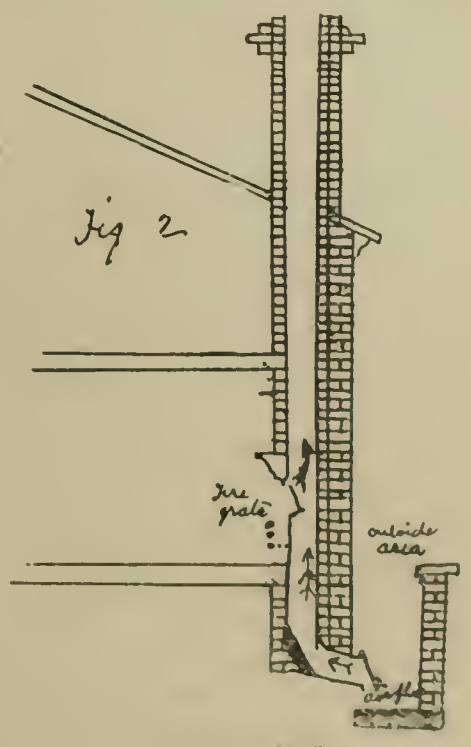
DOWN DRAUGHT IN DOMESTIC CHIMNEYS.

BY W. M. WATSON, TORONTO.

In answer to your query—what will prevent cold air passing down the chimney into your parlor, through the open fire-grate? I may first state the reasons for air doing so, are, because the room is of higher temperature than the outside atmosphere, or even the air contained in the chimney shaft, and the brick work forming the inner

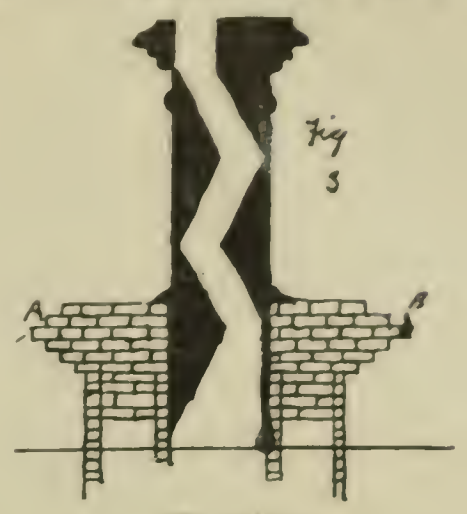


DOWN DRAUGHT.



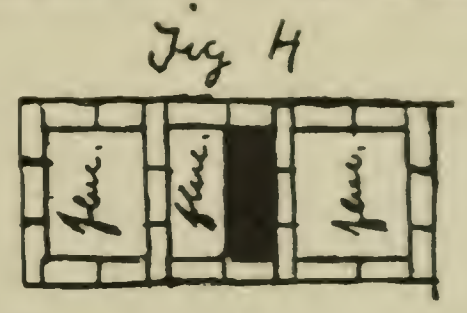
DOWN DRAUGHT.

wall of the shaft. Second, because probably your chimney is built straight and vertical from your grate to the head of the flue, without having any proper bend or goose neck offset, to prevent weight of the heavy, cold, outside air from passing down the full length of the chimney; thus providing an easy route for the outside atmosphere to secure heat by entering and mixing with the air of the parlor. You might possibly prevent it by ventilating your room near the ceiling, through and into the offending flue. This would cool your room, but supply warmth to the inner brickwork of the flue and its contents of air. Your opening, if you adopt that plan, should have the mouth or opening looking up towards the ceiling. If your flue extends down to the basement or cellar where the air is near the same temperature as the air above the roof, then you can stop the nuisance by making an opening that will circulate the air from the cold basement to the housetop by way of the chimney flue causing always an upward current through the shaft. By fitting proper doors, when a fire is needed in



DOWN DRAUGHT.

the parlor, the door at end of flue in basement or outside can be closed, and the one behind the fire grate opened and again reversed when no fire is needed, see figure 2 or third, it might be remedied by making



DOWN DRAUGHT.

a chimney top of galvanized sheet iron similar to sketch 3 and 4 with a bent flue, to take the weight and pressure of the heavy outside air, and act in place of the goose-neck or offset, that should always be constructed near the head of every chimney-flue serving a dwelling-house.

CANADIAN SOCIETY OF CIVIL ENGINEERS.

The annual meeting of the Canadian Society of Civil Engineers was held in Montreal, January 11th. The first business was the election of scrutineers. J. W. Heckman, T. W. Lesage and James Ewing were elected scrutineers of the ballot for the election of officers and members of council; H. B. Stuart and W. G. Matheson, of the ballot for the nominating committee; F. L. Somerville, J. S. Vinden and L. G. Papineau, of the ballot for amendment and by-laws, proposed by members, and J. W. McCarthy, L. J. Maven, and L. A. Amos, for the ballot for amendment to by-laws proposed by the council.

The meeting was then adjourned in order that the members might avail themselves of the invitation of the Royal Electric Co. and the Chambly Power Co., to visit the works, now nearly complete, at Chambly, Que. The Grand Trunk and Vermont Central railways provided a special train, and upwards of 130 members of the society took part in the excursion. On their arrival they were received by S. T. Willet, president of the Chambly Co., and Senator Thibaudeau, president, and W. H. Browne, general manager, of the Royal Electric Co. It is unnecessary to add anything to the illustrated description of this plant in our December number, except that the visiting engineers expressed their high approval of the work, and their sense of its commercial importance. After the inspection luncheon was served in the switchboard chamber, where speeches were made by the Mayor of Chambly, S. T. Willet, G. H. Duggan, Senator Thibaudeau, W. H. Browne, P. St. George, J. A. L. Strathy, and W. McLea Walbank. While at Chambly some of the visitors took the opportunity to visit the old fort built by Mons. de Chambly, in 1711. On the return journey to Montreal, the train was stopped at the Victoria Bridge, so that the members might have an opportunity of inspecting the superstructure in process of erection there. In the evening, the annual banquet was held at Windsor Hotel and was largely attended. C. E. W. Dodwell, of Halifax, acted as toast master, and his genial originality and ready wit contributed much towards making the dinner, what it certainly was, the most successful and enjoyable one ever held. The adjourned meeting was resumed at about 10.30 a.m., on Wednesday. In the

absence of T. C. Keefer, C.M.G., President, and Messrs. Jennings and Thompson, vice-presidents, G. H. Duggan occupied the chair. The secretary, Prof. C. H. McLeod, read the report of the Council for 1897, which was as follows :

ROLL OF THE SOCIETY.

The elections comprised eight members, fourteen associate members, one associate, and fourteen students. Ten associate members have been transferred to the class of members, and four students to the class of associate member. Resignations have been received from two members, one associate and one student. The deaths have been:

Members—Alan MacDougall, H. F. Perley and D. A. Stewart.

Associate members—James R. Peddar and H. L. Langevin.

Associate—John H. R. Molson.

At present the membership stands as follows:

	Non Res.	Res.	Total.
Honorary members	6	2	8
Members	231	53	284
Associate members	115	30	145
Associates	28	13	41
Students	99	35	134
Total			628

At the same date last year:

	Non Res.	Res.	Total.
Honorary members	6	2	8
Members	218	53	271
Associate members	115	30	145
Associates	27	15	42
Students	94	31	125
Total			591

It will be seen that the number of members, associate members and students, i.e., the active membership of the society, has increased during the year. The total increase in the membership of all classes is thirty-seven. At the time of the last annual general meeting there were eight new applications, and at the present time there are nine applications for admission into the society.

The eleventh annual meeting was called to order at 10 o'clock a.m. Tuesday, Jan. 12th, 1897, Herbert Wallis, president, in the chair. Fifteen ordinary meetings were held during the year, at which the following papers were read : A New and Cheap Method of Dressing Car Wheels, by R. Atkinson, M. Can.Soc. C.E.; Fraser Valley Reclamation, by R. E. Palmer, Assoc. M. Can. Soc. C.E.; The Old Albion Mines Railway, by the late D. A. Stewart, M. Can. Soc. C.E.; The Separate System of Sewerage in Ontario, by Willis Chipman, M. Can. Soc. C.E.; Fortifications, by C. R. F. Coutlee, Assoc.-M. Soc. C.E.; Results of Experiments on the Strength of White Pine, Red Pine, Hemlock and Spruce, by Prof. H. T. Bovey, LL.D., M. Can. Soc. C.E.; Sewage by Subsoil Irrigation, by E. Mohun, M. Can. Soc. C.E.; Impulse Water Wheels, by J. T. Farmer, student Can. Soc. C.E. Abstracts have also been read on the following subjects: 1. Water Power, its Generation and Transmission; 2. Water Power of Caratunk Falls; 3. The Transverse Strength of Beams; 4. The Underpinning of Heavy Buildings; 5. Methods and Results of Stadia Surveying; 6. The Liverpool Water Works; 7. Relative Tests of Cast Iron and Strength of Cast Iron; 8. The New Water Scoop of the Pennsylvania Railway; 9. Water Power and Compressed Air Transmission Plant for the North Star Mining Co.; 10. Foundations of Tall Buildings; 11. Solar Work in Surveying; 12. Through Barren Lands; 13. Comparative Tests of Steam Boilers with Different Kinds of Coal; 14. Paint as a Protection for Iron; 15. Inclined-Plane Railways; 16. 100 Feet Standard of Length of Boston Water Works; 17. The Manufacture and use of Sand Cement; 18. Some Experiments on the Condensation of Steam; 19. An Electrical Method of Measuring the Temperature of a Metal Surface on which Steam is Condensing. A series of lectures on the "Transmission of Power by Compressed Air, Gas and Steam," by Prof. J. T. Nicolson, B.Sc., M. Can. Soc. C.E., and Prof. R. J. Durley, B.Sc., Assoc.M.Can.Soc.C.E., were delivered during February and March of this year. The lectures were illustrated by lantern projection, and attracted very large audiences. They are now published in condensed form in Vol. XI., Part I., and constitute a valuable contribution to the published transactions of the society. An illustrated lecture on "Cantilever Bridges," by Mr. J. A. L. Waddell, Ma. E., bridge engineer, of Kansas City, Mo., was delivered at the meeting of October 28th.

The accommodation of the society has been enlarged during the year. The council at its first meeting appointed a committee on Dominion Legislation, but the committee has not deemed the time opportune to take any action. The several provincial committees on legislation, as constituted last year, were re-appointed. During the year additions have been made to these committees owing to the death of two of the members and the resignation of others. The committees are now constituted as follows: Nova Scotia—M. Murphy, C. E. W. Dodwell, W. R. Butler, W. G. Matheson and H. S. Poole. New Brunswick—P. S. Archibald and Hurd Peters. Quebec—St. George Boswell, L. A. Vallee and E. Marceau. Ontario—W. T. Jennings, M. J. Butler, Willis Chipman and W. G. Thompson. Manitoba—H. N. Ruttan, G. H. Webster and J. Woodman. N.-W. Provinces—W. D. Barclay, G. A. Stewart and W. I. Thompson. British Columbia—G. A. Keefer, H. J. Cambie, A. J. Hill, H. Abbott and F. C. Gamble.

In October the council appointed H. Wallis, W. J. Sproule and C. H. McLeod, a special Central Committee on Legislation with power to add to its number H. Irwin has been added to the committee. Since its appointment this committee has, in conference with the Quebec Provincial Committee, given a large amount of time to the promotion of legislation in Quebec. In Nova Scotia the Provincial Act was, in January last, passed through the Lower House, but consideration of it was deferred in the Legislative Council, and it will be necessary to reintroduce the bill during the session which will open some time in January.

At the first meeting of Council W. J. Sproule resigned, and his place was filled by the appointment of E. Marceau. On June 8th C. H. Rust was appointed a member of council to fill the place made vacant by the death of Alan MacDougall. On October 12th G. H. Duggan was appointed a vice-president in the place of Prof. H. T. Bovey, resigned, and W. J. Sproule was elected to the council to replace G. H. Duggan.

Signed. T. C. KEEFER, President.
C. H. MCLEOD, Sec'y.

This, together with the treasurer's report, and that of the Library Committee, was adopted. Some discussion on the arrears in subscriptions followed the treasurer's report, motions were made and withdrawn, and finally the council was left to use its own discretion in individual cases as formerly. K. W. Blackwell, the treasurer, referring to the legacy of $500 left by the late H. G. C. Ketchum, said that the council felt it had no power to dispose of it, and thought that the meeting might specify the purpose to which it was to be devoted. Herbert Wallis, in reporting progress on behalf of the Committee on Legislation, said that after a great expenditure of time and energy in Quebec, the Close Corporation bill had passed and, notwithstanding some alterations, the bill was now substantially in the form they had labored for all along. This scheme is not a selfish thing. It will benefit those who come after us, said Mr. Wallis, by materially raising the status of civil engineers. Our secretary (Prof. C. H. McLeod), has labored splendidly, and our connection with McGill University has been of undoubted value. Nor must we forget the great credit due to Messrs. Marceau, Boswell, Vallee, Irwin and Sproule. The bill awaits only the sanction of the Lieutenant-Governor to become law. He heartily congratulated the society. Some desultory remarks followed on the subject of the bill, and the secretary announced that some copies of it had been printed, and could be seen at any time by members of the society. The chairman, G. H. Duggan, said he thought the incoming council would like some instructions how to proceed in other matters connected with legislation.

The chairman then called on Prof. Butler for his report on standard measures. The secretary then asked simply that the powers of this committee be continued. The report of the Committee on the Gzowski Medal was received. It recommended that the medal be awarded to Prof. S. L. Fortier, B.Sc., Montreal, for his paper on "The Storage of Water in Earthen Reservoirs."

W. J. Sproule then proposed the following resolution : "That it is in the interests of the engineering profession that the method of doing professional work, for giving advice, for a remuneration estimated by a percentage of the cost of the work to be constructed, is not in the best interests of the profession, nor for the clients of engineers; that its tendency is

immoral, and that this method should be discontinued as soon as possible; and that the attention of all the members be directed in a special manner to this resolution." He said: This is a big question, I know, but not new to many engineers. I believe that the practice is wrong in every respect. That the engineer should be influenced by the idea that the more he makes the work cost, the more comes into his pocket, is only human after all. I do not pretend by any means that all are influenced by mercenary motives, but since the way is open, it is not surprising that weak individuals sometimes fall into such a natural trap. In the case of many small muncipalities where possibly some member cannot even read or write (and there are such), what would be the effect of such a known fact on a designing engineer? This motion was opposed in a fluent and vigorous speech by J. M. McCarthy, who said that such enormities as Mr. Sproule wished to render impossible were no more common in the civil engineering profession than in any other, and might be left to work their own punishment from the popular judgment. He gave some pertinent reasons why the present method should continue to govern professional services. The motion, which was seconded by F. F. Miller, was lost on division.

The scrutineers of the ballot for amendments to by-laws announced the result of the ballot for the amendments proposed by the council. Article 28 was the first attacked. It is as follows: There shall be a council, consisting of the president, vice-president, treasurer, secretary, honorary councillors and councillors, and of this council five shall constitute a quorum. The members of council shall retain their position until their successors have been appointed. It was proposed to leave out the word "secretary" in the second line, and to add to the article "the secretary to be appointed by the council." Lost. Article 35 was the second. It provides that the nominating committee shall draw up a list of voting members qualified to fill the various offices, specifying that of secretary amongst the others, the entire list to consist of 34 names. It was proposed to leave out the word "secretary" and exclude that position from the list of councillors. Lost. Article 19 was the third. This provides that each student shall pay $2 per annum. It was proposed to amend this so that each non-resident student should pay $2 and each resident student $3 per annum. Lost. The fourth proposal was for a new by-law, as follows: Every new member as associate member shall upon admission to the society, pay a fee of $20, but no additional payment other than the increased annual subscription shall be due from an associate member upon his transfer to membership, which was adopted.

The amendments proposed by the members were all carried. The first referred to by-law No. 27, which is: -The officers of the society shall consist of a president, three vice-presidents, a treasurer, a secretary, a librarian; the past presidents, who shall be styled honorary councillors; and fifteen councillors. Of the fifteen councillors, not more than three may be associate members. The words "last three surviving" are to be inserted before the words "past presidents," and the words "who continue to be members," inserted immediately after the words "past presidents." Article 34 provides for the appointment by the council of committees of five each on finance and the library, without regard to the number which shall form a quorum on each committee. The amendment is that three shall form a quorum. By-law No. 35 is amended to agree with the amendments to No. 27, and will be as follows:

"A nominating committee of eight voting members elected annually and of the last three surviving presidents, who continue to be members, shall draw up a list of names of such voting members as in its opinion are qualified to fill the offices of president, vice-presidents, treasurer, secretary, librarian, and councillors for the ensuing year, and who shall previously to their names being entered upon the list, have signified to the committee in writing their willingness to accept their several nominations."

H. Irwin said that from time to time outside members had complained that they were not represented on the council. This ought to be remedied. Members all over the country should send in a list of those whom they thought ought to be on the committee It is very difficult for the local committee to choose. H. Peters thought that there might be some difficulty about this. Still, while all acknowledge the rights of Montreal, other societies move their annual meetings from place to place. Would it not be desirable for the civil engineers? It would undoubtedly extend their influence. He gave notice that at the next annual meeting he would move that the annual meetings be held in different places. W. J. Sproule thought that this object would be sufficiently met by a summer convention, one of which had been held. An important consideration is that all the records of the society are in Montreal.

The scrutineers then announced the result of the ballot for the election of officers, which resulted as follows: President, W. G. McN. Thompson, of St. Catharines; Vice-Presidents, K. W. Blackwell, P. W. St. George, H. D. Lumsden; Secretary, Prof. C. H. McLeod; Treasurer, H. Irwin.

Members of Council—H. N. Ruttan, Duncan McPherson, C. E. W. Dodwell, G. H. Duggan, E. H. Keating, St. George Boswell, J. H. Shanley, C. B. Smith, J. D. Barnett, F. C. Gamble, J. Galbraith, Hurd Peters, W. McLea Walbank, J. L. N. Coste.

P. W. St. George expressed the thanks of Mr. Thompson, who was unavoidably absent, and also his own for election to their respective honors. The secretary then announced that the retiring president, T. C. Keefer, C.M.C., had sent an address on "The Progress of Engineering Works during the last ten years, and of Water Works in particular." This was read by C. S. W. Dodwell, and will be found reported upon another page.

In proposing a vote of thanks, Jno Kennedy said: "I have much pleasure in proposing a vote of thanks to our president, Mr. Keefer, whose absence we all regret very much. We owe him a great deal. The society honored itself as well as Mr. Keefer in electing him as president for the second time, and much of the success of the society to-day is due to his kind interest in it during the past ten years. Mr. Keefer has been honored by our Queen and by his profession, and I am sure I am speaking for every individual member, not only of the society, but of the profession at large, when I say that all the honor and more is due to him. I say again, therefore, that it gives me great pleasure to propose a vote of thanks to Mr. Keefer for his very interesting address just read, and for his services as president of our society. This was seconded by H. Peters and carried by a standing vote. The meeting terminated with votes of thanks to the Royal Electric Co. at Chambly, the G.T. and C.V. railways, the scrutineers, the Hon. Messrs. Attwater, Duffy, and the other gentlemen who assisted in passing the Close Corporation bill at Quebec, to Prof. C. H. McLeod for his valuable services in the same direction, to the treasurer, K. W. Blackwell, to the St. Lawrence Cement Co., and to the curator of the fort at Chambly.

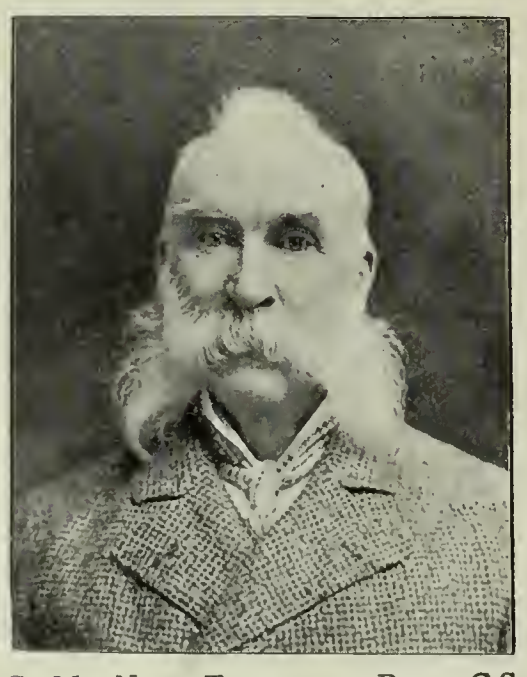
At the regular meeting, held January 20th, P. W. St. George, vice-president in the chair, the secretary announced applications for admission from Chas. Biggar, of Ottawa; H. F. Duck, Toronto; J. W. Fraser, Ottawa; Lewis Skaife, Montreal: for transfer from W. P. Morrison, Halifax; C. C. Wonsfold, New Westminster; students, G. A. Beauchand, E. Lorne-Bond, H. D. Pariseau, L. F. Gagon, H. L. St. George, F. T. St. George, all of Montreal.

A letter was read from Herbert Wallis, announcing the gift of a fire basket and fender for the accommodation of members in the new smoking-room, which, together with a reading-room, has recently been added. It was suggested that something should be done to celebrate the opening of these rooms. Prof. Nicholson suggested an exhibition of slides, illustrating great engineering works. Other members wished this to be followed by something free and easy for once, and in consequence a committee, composed of Profs. McLeod, Nicholson, and Durley, and Messrs. McCarthy and Loveless, was appointed to make the necessary arrangements for a smoking concert.

Prof. Nicholson then read the abstracts of two papers on "Some Experiments on the Condensation of Steam," and "An Electrical Method of Measuring the Temperature of a Metal Surface on which Steam is Condensing." The former by Profs. Callendar and Nicholson, and the latter by Prof. Callendar alone. Prof. Durley said that these papers were likely to impress any hearer of them with the great care and skill displayed by the experimenters, but he thought that the results would hardly appeal at first sight to the practical man. He would ask under what circumstances is the rate of condensation less than that given, and what would be the probable effect if the steam had been allowed to pass through as a current of considerable speeds. To which Prof. Nicholson replied that he could not say off-hand what was the velocity of the steam. The speed was considerably varied, and he could not say that

he found the rate of condensation attributable in any way to the rate of velocity.

J. Farmer, Ma.E., was then called upon for his paper on "Impulse Water Wheels." H. Irwin said he had not much to do with this class of work, but that it was fast coming to the fore, especially in mining districts. Prof. Durley had hinted that Prof. Nicholson had not shown the immediate practical advantage of his experiments. He (H. Irwin) greatly objected to the careless use of the word "practical." Very many men who claim to be considered practical are not practical at all. The theorist may be in advance of the customs of the day, but often the more practical for that very reason. Water wheels had been in use in older countries by "practical men," for a hundred years, and during all this time they had been losing half their power. The advance made in recent years was due largely to such comparatively isolated investigations. Prof. Durley quite agreed with H. Irwin, and meant not that Prof. Nicholson's investigations were without practical value, but it would have been interesting if Prof. Nicholson had shown their direct effect upon the practical use of water wheels. Mr. Farmer says that the higher the speed of the wheel the greater the arc of action. Has the high-speed wheel a greater arc than the low-speed one? Mr. Farmer replied that the arc of action was intended to refer to the time during which the water really acted on the bucket. Prof. Nicholson expressed his appreciation of the value of the paper. He had seen much written upon this subject, but the paper under discussion was the first to give accurate information. On the subject of the arc of action: did Mr. Farmer say whether a number of jets —say three or four—were ever used on the same wheel at different angles to get rid of the friction of the bearings? Mr. Farmer: "Yes. It is given in the Pelton catalogue." Prof. Nicholson: "Could not the defect of these wheels be got over by—say 15 jets?" Mr. Farmer: "It has its limits. He doubted whether more than five or six could be put in advantageously." Prof. Nicholson: "It would be interesting to make experiments with the throttling gate close to the jet." He again thanked Mr. Farmer. Prof. Durley proposed a vote of thanks to the writer of the paper. Mr. Farmer expressed his thanks, and wished that the experiments had been more complete, and the results more definite.



W. G. MacNeil Thompson, Pres. C.S.C.E.

W. G. MacNeil Thompson, who has just been elected president of the Canadian Society of Civil Engineers, is one of the best-known of Canadian engineers. He was from 1852 to 1856 engaged on surveys and construction of Grand Trunk Railway, Canada, from Toronto westward; from 1856 to 1859 he was resident engineer surveys and construction of Welland Railway. From 1859 to 1860, contractors' engineer and agent on River du Loup section Grand Trunk Railway, Canada; from 1860 to 1863, contractors' engineer and agent on reconstruction of Northern Railway of Canada; from 1863 to 1864, engineer and manager for Dyphusys Cassen Mining Co. of North Wales; from 1864 to 1868, engineer and agent for contractor of Ceylon Government railway from Colombo to Kandy; from 1868 to 1872, engineer on surveys and construction of Intercolonial Railway, Canada; from 1872, engineer in charge of survey of Lake St. Louie; from 1872 to 1889, resident engineer southern division Welland Canal enlargement to 14 feet; from 1889 to 1891, resident engineer Sault Ste. Marie Canal, Ontario; from 1891 to 1894, superintending engineer Sault Ste. Marie and Welland canals. At present Mr. Thompson is superintending engineer Welland canals. Mr. Thompson was elected M. Inst. C.E., 1877; M. Am. Soc. C.E., 1879; M. Can. Soc. C.E., 1891; Associate Am. Inst. E.E., 1887.

J. L. N. Coste, C.E.

Jean Louis Napoleon Coste, Chief Engineer of the Department of Public Works, who was elected member of council of the Society of Civil Engineers for the year 1898 at the annual meeting, held on the 12th of January, was born in Amherstburg, Ontario, on the 31st July, 1867. He is the eldest son of N. A. Coste, one of the collaborators of M. de Lesseps, in the construction of the Suez Canal, and of Mathilde Robidoux, a descendant of one of the men who came from Brittany with Jacques Cartier. Mr. Coste received his technical education in France, and was afterwards articled to the late Sir James Brunlees, past president of the Institution of Civil Engineers of England, with whom he remained several years on various maritime works, returning to Canada in 1883, when he was immediately employed on the staff of Mr. Smellie, then Chief Engineer of the Canadian Pacific Railway in Montreal. In November of that year Mr. Coste was appointed on the staff of the chief engineer of Public Works, and was placed in charge of works in Ontario, Quebec, and Manitoba. In July, 1892, Mr. Coste was appointed to his present position, that of Chief Engineer of Public Works, and as such has charge of the following works: (1) Construction of, and repairs to, wharves, piers and breakwaters built by the Federal Government in the Dominion of Canada. (2) The construction and repairs of all river works. (3) The dredging in harbors and navigable rivers. (4) The construction and administration of graving docks. (5) The construction, maintenance and administration of the slides and booms on the Ottawa, St. Maurice and Trent Rivers. (6) The construction and maintenance of inter-provincial bridges, and of all federal bridges in the North-West Territories. (7) The direction of all hydrographic surveys made by the department. (8) The preparation of all reports on the proposed construction by private enterprise of all works in or over navigable rivers.

WATER POWER IN CANADA.*

Having been honored by re-election to the presidency, after an interval of ten years, I desire to thank you most heartily for this renewal of your confidence, and at the same time to congratulate the society upon its record in this the first ten years of its existence, during which total membership and revenue have increased about fifty per cent. Unlike our predecessors in England and America, we, as the offspring of later times, have encountered no early period of suspended animation, but have advanced steadily, if not rapidly, in numerical strength, and maintained satisfactory financial stability. If we have not progressed proportionately in public usefulness or mutual enlightenment, it may be ascribed (in some measure at least) to the fact that some from whom much could be expected are too closely occupied with daily duties to contribute, as they might otherwise do, to our "transactions." Some may be too modest, and some too old, or possibly too indolent.

If, however, we have held our own as we have done in these recent years (which embrace several of world-wide depression), our prospects for the future seem brighter than when we began our organization in 1887. Then our great railway systems were practically completed; and, although this was the case with our enlarged canal systems only as regards the Welland, the work on the St. Lawrence was in an inert condition. Ample leisure was then afforded Canadian engineers for organization, amusement or foreign travel.

Now, however, there is a decided change in our position at home and abroad. Canada is now a colony of national importance, the largest independent member of a world-wide Empire, and none have contributed more to this advanced position than engineers of every class embraced in our society, which, while it excludes none, is composed almost entirely of the constructive rather than the destructive order.

In 1887 Canada was not a mining country; now, recent discoveries over a wide extent of our vast Dominion have brought the mining engineer to the front, and with him the hydraulic and electrical engineer, because water power is almost

* Being the president's address at the Annual Meeting of the Canadian Society of Civil Engineers, Jan. 12th, 1898.

universal in our mining regions from Labrador to Alaska. Our vast prairies, where is grown the most valuable quality of the most important cereal, have hitherto been unable to attract much foreign interest, though accessible to all nations; but the recent discovery of gold has been of such a character as to invite world-wide attention. Its influence (however temporary) cannot fail to produce increased agricultural development in our great North-west.

Since the birth of our society water power has attained a position of immense importance, owing to electrical transmission, which has given rise to new industries only possible where there is cheap and abundant water power, which also secures cheap intense electricity.

The rapid extension of the pulp industry in Canada is one of the results of cheap water power coupled with our abundant supply of raw material, easy reach of navigation, of rail, and the best markets; but the more recent electro-chemical industries are the exclusive products of cheap intense electricity. Here (as in mining) is a new field for the chemical, electrical, hydraulic and railway engineer. I include the chemist among the engineers, because I regard him as such, with the electrician, the hydraulic or mining engineer, producers though not creators of power, and, it may be, the chemical force is more potent than any other. If dynamite is a chemical compound the power-maker or discoverer is worthy to be numbered with the power user.

An electro-chemical industry of recent origin has been established in Canada by the discoverer, a Canadian chemical engineer, Thos. L. Willson. This is the manufacture of calcic carbide for the production of acetylene gas by means of electricity produced by the abundant water power of the Welland canal at Merritton, where the manufacture in commercial quantity was first started in 1896, and from whence the product has already been shipped to England, France, Germany, Italy, Australia and South Africa.

Another electro-chemical manufacture in which our profession is interested (on water power ground), which also depends on cheap electricity, is that of aluminum, for which the raw material is so widely distributed, but for which, as with the carbide, abundant and cheap water power is indispensable.

In view of its importance, owing to its wide distribution over Canadian territory, from the Atlantic seaboard to the Rocky Mountains, where no coal is found, and on account of its vastly enhanced value since the discovery of high voltage transmission, even where it is within the coal fields, I have chosen water power as the subject of some observations for the annual address.

I have heretofore drawn attention to this widely-distributed power outside of our coal regions, as to some extent a substitute for coal, upon the assumption of local application of power in both cases, whether water or steam, and then the vast difference presented itself that with the last the power could be taken to the work, while with the other the work must be taken to the power; for there was no thought then of electrical transmission. The utilization of water power would be very slight and very slow if under the old conditions of advance into the forest (as in the agricultural portions of the valley of the St. Lawrence), because our greatest extent of water power is in the mountainous and sometimes barren regions, not inviting to agriculture, though most favorable for the accumulation, maintenance and uniform distribution of water power throughout the year.

In considering the question of water power generally, and in comparison with steam, it may first be mentioned that while electrical transmission (where practicable) has enabled it to take the place of steam in many situations, the choice in others depends upon the work to be done, as well as upon the cost of fuel. For transmission purposes there are only the questions of the sufficiency and permanence of the power and its superior economy; but for lumber manufacture, although ample water power is at hand, and there is with it no question of ice difficulties, it is found in many cases that steam is preferable, because the mill site may be chosen in the best position for manufacture, shipment and storage of logs, and the waste material furnishes fuel for power. The cost and maintenance of a mill dam in many situations, with the necessary piers and booms for the logs, the damage and risk to mills, etc., during floods, are reasons urged (in addition to the questions of site and fuel) in favor of steam for this industry. But for other purposes the site of the water power (perhaps in a gorge) is unfavorable for many industries on account of difficulty of access and want of service ground; and here is the value of electric transmission of water power.

When adopting water power, one of the most important considerations is the possible need of future enlargement. Where all the water power of a stream of any point is secured by a dam, and this power can be drawn upon from time to time until the whole is applied, we have only to consider cost, and maintenance in the first place, even though the additional power must thereafter be obtained by coal, or transmission (when this last is commercially practicable), not only because the water power is sufficient for many years, but as far as it goes, it is more economical than any other. But if only part of the available water power is needed, and provision for the future must be postponed for financial reasons, then the question of how any future addition can be made without interruption becomes important in proportion to the purpose for which the power is required. If for water supply or electric light, either the original dimensions must be far beyond present wants, or there must be the power of duplication without interference with existing conditions, or else temporary power for this purpose on a sufficient scale, or permanent, if made auxiliary for future deficiency of water. Such considerations affect the question of the economy of water power for certain purposes and under certain conditions where a periodical increase of power must be provided for. It altogether depends upon local conditions whether an artificial water power, as it may be called, will be worth what it costs for any purpose; and more particularly if this is one in which power must be reserved for future needs. Temporary employment of surplus power could not be counted upon to build up permanent industries.

Electrical demand and transmission have created a "boom" in water power, under which in some cases the schemes proposed may become financial failures. There is evidently a limit to the distance to which water can be artificially conducted in order to reach a fall under the most favorable conditions of route. For power purposes the only useful portion of the aqueduct is that which lies below the surface level of water in it, and the value of this is in direct proportion to its size, and therefore, its cost, which includes the cost of all required work above this level. The longer the aqueduct the higher must be the fall which it secures, and the lower the fall the larger must be its dimensions and cost if it is to be efficient. Whether it will be profitable in either case depends upon the cost. Such natural dams of rock as those of Niagara, Sault Ste. Marie, Rat Portage, the Chaudiere, the Chats and others on the Ottawa are natural water powers of the first order; but the artificial powers created by our canals (apart from cost of every canal adjunct to the water channel) would never have been undertaken for water power purposes. There is a popular superstition that there is more in water than its weight, because that weight is felt "all over" as well as on the bottom, and a tendency to ascribe to it a fictitious value. This has possibly something to do with some projects.

In water power the discovery of lowest possible head level is of the first importance, and the one often of the greatest difficulty where this is not controlled by a dam, which (wherever practicable) is the only certain means of fixing it. When a dam does not exist, or is not obtainable, recourse is had to legend and the "oldest inhabitant," who has seldom proved old enough for the occasion. Our canal engineers have, with the best information, found their mitre sills in many cases very much higher than they intended them to be, because the river had gone very much lower than it had ever been said to have done. To secure at all times a required depth it seems necessary to add about three feet to the "oldest inhabitant." When, over fifty years ago, the Government first constructed timber slides on tributaries of the Ottawa, in the absence of any knowledge of the local range of water level, the mouths of these were found so high after the first flood that the timber could not be floated into them until a dam was built for this purpose.

The high-water level is more easily provided against, and is often more important in connection with the tail-race in fixing the wheel level, where the discharge is into a reach subject to great variation, like that below the Chaudiere Falls, where the extreme range between high and low water exceeds twenty-five feet; which, though of short duration, is about three times as great as the same range above these falls. Where the wheels

would be affected, as this is always the case at the season when the rise is greatest at the head, provision may be made to utilize this temporary increase of head level so as to maintain the necessary power during back water.

Where unceasing operation of power is required in our climate, duplication and separation of flumes (and it may be in some cases of tail-race) may, where practicable, warrant the additional cost in thus securing reserve power (as well as of machinery) when any particular channel has a surfeit of ice; as well as by so much contributing to a future enlargement.

Except upon our canals (where the least winter difficulties are experienced), our great water powers have been chiefly used as summer ones. in which the two independent questions connected with water power, viz.: the power of enlargement and extension without interruption, and the possible ice difficulties of a northern site, do not come in question. The large saw-mills have not worked in winter because their logs are frozen in. Before the railway reached them the mills stopped sawing when they could no longer ship their output; but, where they depend upon the water for their logs, whether they are worked by water or steam, they are idle in winter.

The coming of electricity, bringing with it the demand for winter power, has produced ice difficulties where they did not before exist, and were therefore not anticipated and not provided for, although winter water power, to a limited extent, had been in use. Increased power brought increased current, and this under certain conditions brought the submerged ice.

There is no question of more importance to our water powers than this one of uninterrupted operation in our northern districts where nearly all are located, and where (with perhaps the exception of the southern portion of our Pacific coast) ice in one form or another must be dealt with. It assails the moving water sometimes both from above and below, and, if undiscovered, chokes off the motive power.

In artificial channels the fixed surface ice above may diminish the water power by its increasing thickness and depression from superincumbent weight of snow saturated by winter rains and thaws, and, where these channels are fed from open water in which floating slush ice is moving, the latter may be drawn in to increase the throttling of the reduced water-way. The situation is greatly complicated by winter fluctuations of the open water from which the mill-race is fed, and in which the "slush" or "anchor ice" is running, a not uncommon situation in northern rivers which cannot be conveniently dammed or where sufficently large receiving basins cannot be created so that "slush" or "anchor ice" will not enter and travel through the mill pond to reach the flumes.

The ice question can be more fully appreciated by what has taken place in connection with water powers at Montreal and Ottawa. In the first case, the aqueduct of the Montreal water works, five miles in length, almost entirely in excavation, is fed from the St. Lawrence above the Lachine Rapids, where there is a smooth, swift current which prevents the freezing over in winter, but is often covered with "slush" or "anchor ice" when that is running. The Lachine Rapids below the intake of this aqueduct are of that ragged character that temporary ice dams often form and break away during the winter. These dams produce a sudden rise which extends to the aqueduct two miles above.

From the setting in of winter until March the river level steadily lowers, except when temporarily elevated by the ice dam, so that in the early spring there is the least depth of water at the intake, and the greatest depth of surface ice and saturated snow over the aqueduct, and the only water-way left is at the bottom where the width is least. The ordinary action of snowfalls, winter rains and thaws (the accumulations of three or four months) would of themselves seriously encroach upon the water-way in the widest part of its earth section, but these are (in this case) enormously increased by the sudden rise of the river while the ice is frozen to the aqueduct banks. This ice is overflowed before it can be lifted, and as these winter floods always occur during the severest weather, the overflowing water is immediately frozen, forcing the ice covering of the aqueduct further down until the half of more of the area of its water-way may be closed off.

These winter inundations seldom last long enough to send the river water far down the aqueduct, but their action at its mouth is all that is necessary to affect its power. The first one experienced was during the first winter the works were in operation. Nothing like it has taken place in the forty years which have since elapsed, and it was the only one which extended throughout the five miles of the aqueduct. In January, 1857, after nearly five days of below zero weather, in the middle of the night the water suddenly poured over the flumes in the wheel-house, sending an icy stream over the frozen surface of the ground for miles beyond. This ice-dam on the rapids caused a rise of four feet in a few hours at the aqueduct entrance. Years later this flood might have destroyed the usefulness of the aqueduct for the remainder of the winter, but the power then required was so small that winter difficulties did not arise until a later date, when the conditions were aggravated from another direction—below instead of above, and from another description of ice insidiously creeping into the winter-diminished water-way, due to the causes above described, and producing gradual suffocation. This did not take place until the combination of extreme low water in the river, extreme accumulation of surface ice and snow and increased draught to the wheels so quickened the current at the intake that it attracted the floating frasil or "anchor ice," which immediately that it touched the solid bordage ice at the aqueduct entrance was sucked under and soon arrested where the strangling process was slowly but surely closing the gap.

The lesson of this history is that in such situations, where anchor ice is wont to pass an intake basin is indispensable where possible, so large, wide and deep that the necessary supply for the power channel coming into it from the river will never create a current sufficient to attract the frasil. Anchor ice is only begotten in open water, and this in our climate always means water too swift to become self-freezing; and it will not leave this until enticed from the old paths by stronger currents. It is, therefore, only a question of cost to form a mill pond which it will not invade. Where this is limited, the boom which separates the river from the basin (forming a bordage to the ice cover of the latter) should be made deep enough to prevent the ice which is passing and crowding outside from being forced under it.

An enlargement of the aqueduct was undertaken twenty-five years ago, but it was not carried farther than seven-eighths of a mile from the entrance. It has prevented the incoming of anchor ice and enabled the aqueduct in high water winters to pump its full summer average. But, as the strength of a chain is that of its weakest link, so, for this purpose, the minimum power must be equal to the maximum wants, and auxiliary power will be required until the completion of the enlargement. Enlargement is not likely to be completed until the consumption is so increased that it will become cheaper to pump the whole by water power.

In high water mild winters when there is the minimum of ice obstruction, and an increased depth at its widest section, the aqueduct pumps its full summer average. Thus in March, 1890, it pumped 350 million gallons, while in March, 1893, it only pumped 46 millions, because when the river falls to a certain level all wheels are stopped to prevent further lowering of the ice in the aqueduct. This result would go to prove that, to meet our winter conditions in some situations, an increase of at least fifty per cent. on the necessary summer dimensions would be needed.

Until water power was required for pumping the city water supply, in 1874, there had been no important winter use of the power of the Chaudiere Falls. The large saw mills did not work after November. The few establishments on either side of the river where winter water power was used had no effect on the ice question, nor did the larger demands for the city pumping change the conditions in this respect. The advent of electricity, however, in which three large users of power engaged, revealed the fact that winter difficulties existed where they had not been anticipated. Fortunately, they have not yet seriously affected the city aqueduct, where, in the absence of auxiliary power or reservoir, they might produce a calamity.

The conditions at Ottawa differ from those at Montreal inasmuch as the aqueduct is fed from Nepean Bay, which is ice-covered in winter, and all the other mill-races upon the Ontario side draw under similar conditions. About a mile above these the foot of the Little Chaudiere Rapids is reached, and this is united with another rapid higher up, so that there is over a mile of open river in which anchor ice is manufactured and sent below in successive and frequent crops in severe winters. On the north, or Quebec side of the river, runs the only deep channel between the Little and Great Chaudiere. This is generally open water throughout the winter, and in it much of the anchor ice is carried into "the Kettle" and away from the mill ponds on either side. From this a subsidiary channel of considerably less depth crosses diagonally to Nepean Bay, discharging

into a depression in which there is a depth much greater than that of the channels leading into and out of it, and therefore a slower current. This is the point from which the supply to the city aqueduct is taken, and, in leaving it, the aqueduct begins between piers sixty feet apart placed in twenty feet of water, whereas the section through the rock after it leaves the river bank is only twenty feet wide with about thirteen feet depth of water. The excavation being entirely in rock, this aqueduct has the great advantage, for winter work, of having as great a width at the bottom as at the surface.

It was not known that any frasil passed through this bay under its ice covering, but it was believed that, if, and when it did, the slower current into the aqueduct would not attract it, and that it would pass outside in the main channel leading to the mills below. This has proved to be the case in the twenty-three years of the aqueduct's history, although there has been some frasil in the later years, causing a stoppage of the wheels on one occasion, for a few hours, by which stoppage its presence was first made known.

Unless anchor ice is expected and watched for, the first indication of its presence may be a sudden collapse of the water power. When the Montreal Aqueduct was first corked up at its mouth by anchor ice the wheels ran on until the five miles of canal was emptied, and the ice tumbled in, ruining it, as an aqueduct, for the time being. The same experience overtook the electrical power at Ottawa, and from the same causes, but under different conditions, emphasizing the necessity of local knowledge of bed as well as of the surface of the channels near and above the site of the power.

The whole Ontario side of the river bed is a submerged rocky plateau ten to thirty feet or more above the bottom of the north channel, so that if the river surface here at low water were lowered ten feet it would lay dry the greater portion of the southern half of the river bed, while there would still be deep water in all the north channel above the rim of "the kettle." As at Montreal, in a moderate and high water winter ice difficulties are not experienced, but, in very severe and low water winters, the thickened ice settles down on top of the shoals, reduces the depth and increases the current in the channels between them until one after another is invaded by frasil, coaxed in by the increasing draft towards the water power, and gradually shut off.

In these winters the output of anchor ice is a maximum, while the storage room beneath the field ice is reduced to the minimum. Moreover, as channel after channel is closed, the velocity in the remaining ones is so increased that the anchor ice is carried under miles (it may be) of an ice-covered surface, until it reaches the mill-races.

That anchor ice is carried long distances under the surface of an ice-covered river (or shallow lake with sufficient current) is proved by watching air holes near Montreal, where this ice is seen hurrying past, having come over the Lachine Rapids, below which none is formed after the river becomes ice covered.

On the other hand, in mild and high water winters there is the minimum of ice of all kinds, and the maximum depth of channel, and therefore the slower currents in them, so that anchor ice is arrested by friction under the field ice and frozen thereto, leaving some water-way underneath it.

The best way to fight anchor ice (which is the sole cause of the winter floods in the St. Lawrence) is to abolish it wherever this is practicable. It cannot be got rid of in the St. Lawrence, but could be at Ottawa by a dam at the Little Chaudiere. This could also be done in the Back River behind Montreal by a succession of dams, creating slack water (and water power) if this can be accomplished at a profitable outlay. On most of our tributary rivers this hoary enemy of water power can often be got rid of and a valuable water power created at the same time by means of one or more dams.

THE STEAM ENGINE GOVERNOR AND ITS REGULATION.*

The matter of governing steam engines for a uniform speed under the greatest variation of load and steam pressure, and the economy in the use of steam, is no doubt one of the principal features in steam engineering, and I believe the same is absorbing more thought and receiving more attention from the engineer and engine-builder than any other subject connected with the steam engine to-day. I will now endeavor to point out the fundamental principle upon which the governor acts, and why it acts. There are two principles on which governors are constructed, one known as the centrifugal, and the other inertia action. The ordinary centrifugal fly-ball governor consists principally of a pair of cast iron balls or weights, suspended on an arm and at an angle of about thirty degrees from its vertical axis, and made to revolve round its axis as free as possible, generally driven by a pair of mitre gears. This principle of fly-ball or centrifugal governor was embodied in the first governor invented by James Watt, which has been more resorted to than any other, but aside from this the governor has been so improved and altered, and reconstructed since his time as to be almost unrecognizable, but still the old principle is there, and nearly, if not all, the prominent defects which so materially interfere with its efficiency.

The three principal defects are: First, friction; second, unbalanced force, caused by the different position of the levers and arms; third, unequal resistance, offered to counteract the centrifugal force. Now we will take friction, the first. It may be said it has been fairly well overcome for the most practical purposes, so far as the builders are concerned, but much depends on the engineer, as it is his place to see that no excess friction is allowed through improper lubrication of the working parts and poorly packed valve stems, etc. Second, unbalanced force: This defect appears to be much more difficult to overcome, and is certainly a greater detriment to the action of the governor. Like other parts of the steam engine, some governors are designed much worse than others in this respect, but the best of them are a long way from being perfect, and the reason may be explained in this way: Suppose we take, for example, the ordinary centrifugal fly-ball governor, and assuming the balls are traveling around in their normal plane, and say the arms are now at an angle of 45 degrees and traveling through the path of a 12 circle. The engine is now running 100 revolutions per minute, and the mean effective pressure is 40 pounds. Now, so long as those conditions are left that way, and there is no change in the load, the speed of the engine will be most perfect, but we cannot maintain this, so we will suppose the first change to be that the steam pressure shown by the gauge is allowed to increase. Now then, the mean effective pressure shown by the gauge becomes greater, and the engine then begins to move faster, and the governor in turn. Now there has been a change. The balls have moved to a higher and wider plane. This change simply means that the line of force has become closer to right angles with the vertical axis of the governor, therefore traveling through a greater radius, and the line through the point of gravitation has become further away from the fulcrum, therefore the speed has to be increased to overcome the increased weight of gravity, caused by the change of angularity, and so the engine continues to increase in speed until enough momentum has been stored to balance the balls in their new position. So then it is quite consistent that the force that will support the balls in one plane will not support them in a higher one. Therefore, the speed of the engine must vary when controlled by such a governor. Third, unequal resistance offered to counteract the centrifugal force. This is sometimes applied by a lever and ball, and sometimes by a spring. Where the ball is used we still have the same trouble as in the fault of the second, namely, angularity; and where the spring is used it is much worse than the ball, because the tension of the spring increases as the spring is drawn out. For example: If we have a spring attached, and offered 20 lbs. resistance, when it was drawn out, say one inch. Supposing now that part of the load was thrown off, the balls would then have to be speeded up to a higher plane, say enough to cause the springs being drawn out another inch; then the spring would be holding 40 lbs., and of course the balls would have to be speeded fast enough to support this extra 20 lbs.; possibly this might mean two or three revolutions faster for the engine.

The object of applying resistance to the governor may be said to have two purposes. First, to assist the gravitation of the balls when coming to a lower plane. Second, to permit the changing of the speed of the engine by adjusting the ball or spring until the required speed is maintained. This resistance, however, has been made automatically adjustable by several inventors in the last few years. This has bettered matters considerably, but still the speed of the engine must

* A paper read before the Hamilton branch of the Canadian Association Stationary Engineers, by H. G. Mitchell, President Ontario Association Stationary Engineers.

change before the attachments are caused to act. So as it is, the engine has first felt the change of load, causing it to slow up in speed, then the governor feels the change, which in turn causes the attachment to act; therefore it is just a little too late in acting, as the speed has already slowed up, but if the governor had felt the change before the engine, then things would have been different; and so it is with the centrifugal governor that the momentum has to be increased to act one way, and decreased to act the other way. Now, I will leave the centrifugal governor and take up the other principle of governor, called inertia. As it would make this paper very lengthy to go fully into this, I will only endeavor to touch on a few principal points.

First, we will suppose the inertia to be connected on a shaft governor. The principal part of this apparatus consists of one straight arm with a fixed weight on each end, and pivoted in the centre to a fixed point of the wheel near the centre of the shaft, thus allowing the balls to move in a rotating direction only, and always in the same plane, thereby doing away with the troublesome change of angles, as well as the use of the centrifugal action. There is a spring attached to the arm about the centre of its radius and the other end to the rim of the pulley which surrounds the governor. This spring is used to offer resistance to the acting energy of the rotating weights, and also to assist the momentum in opening the valve. Now, it will be seen that when this apparatus is put in motion the pulley and engine will gradually advance ahead of the suspended weights and continue on so until the valve is adjusted to the proper cut-off to balance the load, and when any extra load is felt by the engine the weights will continue to go on in advance of the engine, thereby increasing the travel of the valve, and permitting a later cut-off. So with this apparatus there is no reversing of motion before the governor responds.

THE TORONTO CITY HALL.

There are some people of so critical a nature that they are invariably opposed to the course of action pursued by all those who are in authority over us. Like the Scotch elder, they can "aye object." These are useful, if objectionable people. They occasionally cause an arrest, which is a public service, and to be commended, even though the everlasting cries of "Stop Thief" disturb our after-dinner nap. The opposite class in the community believes that everything that is is right. He believes in the divine right of kings, aldermen and pickpockets. He always votes for the Government, whatever it may be and is a man such as Cæsar likes, who "sleeps o' nights."

Between the critic who is never satisfied and the man whose creed is, "All's well in the world," THE CANADIAN ENGINEER wishes to pursue a middle course. To praise where we believe praise is due, and to blame where we believe cause for blame can be found; and there is the rub. To the end that we may discover if any cause for blame anywhere exists, we intend to ask a few questions, the answers to some of which would determine the fact. In another issue we will take up the question of praising the praiseworthy features, and they are many, of the city hall.

When Elliott & Neelon accepted the contract for the masonry work on the city hall at $838,061, did they expect to make a profit? If they did, how is it that the architect has spent all but a small sum of this amount, and has not yet quite completed the work called for under this contract?

Are we correctly informed that the execution of the work on the lines laid down in the specification upon which this contract was let would have left a very large profit?

Assuming that this profit would have been made by Elliott & Neelon, why has it not been made by the city?

Has the fact that there would have been some question as to whether Mr. Lennox would have been paid his 4½ per cent. on the amount of the profit anything to do with the fact that it has disappeared?

The specifications call for a wall, which was practically a brick wall with a stone facing. As it stands to-day, the building is a stone building, whose walls are of stone with a brick lining.

Are we correctly informed, when we are told that there is 10,000 feet less radiating surface now in the building than the specifications for the heating plant called for? Such a change as this would, of course, only make a small difference in the total, amounting to between $3,000 and $4,000, and we understand that Mr. Lennox is empowered to make any changes that he may see fit.

Of course, such changes will be allowed for and may offset other changes which would otherwise figure as extras.

A short time ago when the architect was instructed to forthwith prepare plans for the dado of the entrance hall, he declined to do so on the ground that he had to accompany a contractor to the United States to select some appliances for the building. In the ten years in which the plans have been in course of alteration, it would appear possible to have prepared even alternative sets of such detailed drawings as these.

Does the architect journey to and fro, assisting all contractors to select their material, and if so, at whose expense?

THE NIAGARA POWER COMPANY.

We have all along expressed the hope that the Ontario Government would take some decided action to undo the great wrong which they committed when they handed over the water-power at Niagara Falls to an alien company, and one whose best interests were served by the least possible development on the Canadian side of the river The session has been allowed to pass and nothing has been done. The only indication of any intention or desire on the part of the Government to make of the resources of Ontario anything greater than a pleasure ground for the United States tourists, or dividend earners for United States capitalists, is the following letter written by the Hon. A. S. Hardy, Premier of Ontario, to F. W. Hill, mayor of Niagara Falls, Ont., a short time ago:

Toronto, Jan. 19 1898.

DEAR SIR,—In reply to your question as to whether it is the intention of the Government to grant to the Canadian Niagara Power Company an extension of time for either the beginning or completion of their work on this side of the Niagara River, I beg to say that in April, 1897, in reply to an application, the company was informed that the agreement made no provision for an extension of the time for either the beginning or the completion of the work, and that it did not appear possible to the Lieutenant-Governor-in-Council to grant such an extension. This appeared to be accepted by the company as final and conclusive, and no further application has been made since then I feel quite at liberty to say that there is no change in the policy of the Government on this point, and that should a further application be made for an extension it is the intention of the Government to adher to this policy and to the terms of the contract.

I am, etc.,

Very truly yours,

A. S. HARDY.

F. W. HILL, Esq., Mayor Niagara Falls, Ont.

The question still remains an open one, for so far the Company has complied with the terms of its contract, work was begun within the stipulated time, and the only hope of the promise contained in this letter being carried out, that the company does not carry out the work within the date set within the contract. It is merely a question whether it wishes to hold the monopoly or not; with the resources in men and money which the company can command, it would be possible to deliver the required number of horse-power within the time specified, but the performance of the work in the time which is now left would be exceedingly expensive, and could not be done to the best advantage

If the Niagara Falls monopoly wishes to retain the industry of southern Ontario in its death dealing grasp, it can do so. If it does not so wish, Premier Hardy will not compel it. That is what the letter may be said to mean.

LITERARY NOTICES.

"British Columbia and the Canadian Yukon Year Book" for 1897, by R. E. Gosnell, Librarian and Secretary, Bureau of Statistics, Victoria, B.C., has just been issued. It is one of the most comprehensive works on British Columbia published in recent years. It contains over 500 pages, eighty of which are occupied by representative illustrations. There is a series of specially engraved maps, and eight lithographic diagrams illustrating British Columbian progress. A special chapter is devoted to Klondyke and the Canadian Yukon, with latest map issued, showing routes. The table of contents is arranged under headings, such as Historical Review, Parliamentary and Judicial, Municipal, Educational, Indians, Physical Characteristics, Forests, Fisheries, Agricultural, Mining, Sociological, Trade, Railways, Canadian Yukon, etc., etc. Price (postage free), in cloth, $2 50; in paper, $2.25. R. E. Gosnell, Librarian Legislative Assembly, Victoria, B.C.

We find in the Methodist Young People's paper *Onward* the following expressions about the Canadian press. Our readers will have no difficulty in recognizing the *Montreal Witness* as the paper specially referred to: "Nowhere, we think, is there a press of higher moral tone than that of our beloved country. It possesses, we think, the unique distinction of having a leading journal in its largest city which for over fifty years has been a moral crusader, a champion of reform. In all that time it has not published one liquor, or tobacco, or theatrical advertisement. At the sacrifice of much money it has stood true to its high principle, and stands foursquare, a tower of strength, against all the winds that blow."

ASSOCIATION OF ONTARIO LAND SURVEYORS.

The following papers are expected to be read at the annual meeting of the Association of Ontario Land Surveyors: "Drainage," John H. Jones, O.L.S., Sarnia; "Irrigation Works on Dominion Lands," A. W. Ponton, O.L.S., Regina, Ass.; "Unrecorded Original Field Notes," J. J. Murphy, Crown Lands Department, Toronto; "Acetylene Gas and its Uses," V. M. Roberts, O.L.S., St. Catharines; "Evidence," M. J. Butler, O.L.S., LL.B., Napanee; "Lake Erie Survey, Otto J. Klotz, O.L.S., D.L.S., Ottawa; "Sudbury Water Works," S. V. Rorke, O.L.S., Sudbury; "Use of Field Tile for Large Drains," W. M. Davis, O.L.S., Woodstock; "The Economic Resources of the Hudson Bay District," J. W. Tyrrell, O.L.S., Hamilton; "Assessment Plans," P. S. Gibson, O.L.S., Willowdale; also papers by Jas. Hutcheson, O.L.S., Guelph; F. W. Farncomb, O.L.S., London, and several others. The date of annual meeting of the association is fixed for 22nd February, but arrangements are being made to meet on that date *pro forma* and adjourn to 8th March. The Board of Examiners will hold its annual meeting at the Department of Crown Lands, beginning 14th February.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

On Saturday evening, January 15th, in Temperance Hall, Bathurst street, Toronto, Toronto Branch, No. 2, C.A.S.E., was duly opened and the following officers installed by Executive President E. J. Philip, assisted by the officers of Toronto No. 1: Past President, P. Trowern; president, John Dixon; vice-president, John H. Venables; recording secretary, Thomas Graham, 570 King street west; financial secretary, J. Richardson; Treasurer, Joseph Hughes; finance committee, F. Tushingham, E. Thomas, T. L. Holmes; trustees, John Dixon, J. McMulken, P. Trowern; conductor, M. Connolly; doorkeeper, H. Brown. Immediately after the installation ceremonies were over President Dixon delivered his maiden speech, and, in conclusion, invited the visiting brethren from Toronto No. 1 to partake of refreshments, which were duly appreciated and ample justice done to the elaborate supper, which was served by the wives and daughters of the officers. After the usual toasts, speeches and songs, the gathering dispersed with the singing of "Auld Lang Syne."

The regular meeting of Toronto No. 1, C.A.S.E., was held January 19th. There was a large attendance, and one initiation. The committee appointed to get up the annual At-Home and reopening of the hall reported that all arrangements had been completed to hold the At-Home on Thursday evening, Feb. 3rd. A general good time is guaranteed. Tickets, 25 cents. There is to be a concert, refreshments, dancing, and other amusements. The trustees reported that they would have to draw on the association funds, the insurance allowance not being enough to finish furnishing and decorating the hall, but when complete the engineers will certainly have one of the finest suites of rooms in the city. Bro. Wickens will continue his paper on the "Indicator" at the regular open meeting on Tuesday, February 8th. All engineers and manufacturers are invited to be present.

—We have received the fifty-first volume of the Canadian Almanac from the publishers, Copp, Clark Co., Limited, Toronto. Besides being a directory of clergy, militia, Government officials, members of Parliament, county and municipal officers, schools and colleges, barristers and solicitors, and other public men, it is a compendium of information of all kinds relating to Canada. Some of the more prominent departments are: Short History of Canada, Tariff of Customs, Forms of Government throughout the World, Post Office Gazetteer, Masonic Lodges, Miscellaneous Societies, Historical Diary, Life Insurance. Some new features for 1898 are: Short Accounts of the British Army and the British Navy, with illustrations; also articles on the English Government, and Extradition and Pardons. Besides the above, with every copy of the Canadian Almanac for 1898 is presented a map of North America, beautifully engraved and printed in five colors. The price, 25 cents.

—W. B. McKenzie, chief engineer of the I.C.R, has an article in the New York *Engineering News* recently, on the "Tidal Marshes of the Bay of Fundy." Between the Bay of Fundy and the Strait of Northumberland lies a strip of low land 15 miles wide. During the post-tertiary submergence, this part of the country was 220 feet below its present level, and the Champlain and the Saxicava sands were being deposited on the sea bottom. Tides of the ordinary height, 10 to 15 feet perhaps, swept across into Northumberland Bay. Mr. McKenzie states floating ice was carried in both directions and has left its deep grooving on the bordering shore. Several shore terraces, now standing high above the sea, tell that the land rose spasmodically. When the 'divide' appeared, the Isthmus of Chignecto was low, and the eastern part was no longer an island. The tidal wave was thrown back upon itself, and while recovering from the shock lost part of its load or sediment. Since then, the tides have been depositing this material and filling up the valleys and fresh water streams flowing into the Bay of Fundy, forming these great prairie-like salt marshes which now constitute much of the agricultural wealth of New Brunswick and Nova Scotia.

Industrial Notes.

THE Stempel Fire Extinguisher Company has removed from Berlin, Ont, to Toronto.

THE Paris Electro Plating Company, Paris, Ont, has sent its friends an attractive calendar.

THE employees of the Westinghouse Air Brake Co, Hamilton, Ont., are working 13 hours per day.

THE Stouffville, Ont, waterworks were tested January 14th, and gave complete satisfaction it is reported.

EDISON FITCH, Etchemin, Que., will shortly build a new woodworking factory, stone, 134 x 43 feet, to cost $12,400.

THE Stratford Bridge Co. is building a highway bridge 110 feet long at Greenfield, Waterloo county, Ont.; cost, $1,084

HARVEY & Co., merchants, St. John's, Newfoundland, have started up their pulp factory, at Black River, Placentia Bay.

THE Goldie-McCulloch Co., Limited, Galt, Ont., will enlarge its offices and extend the molding shop, owing to the enlarging business

THE by-law granting a bonus of $62,000 to the Abbott Rolling Mills Co. was carried in Kingston by a very large majority, Jan 13th

THE Smith Axle Works Co. is consolidating its business in Guelph, Ont, some carriage hardware formerly made in London being now manufactured there.

THE thirteenth annual meeting of the Illinois Society of Engineers and Surveyors, was held in the Court House, Peoria, Illinois, January 26th, 27th and 28th, 1898.

THE officers of the Halifax Board of Trade for the year are: President, Geo. Mitchell, M.P.P.; vice-presidents, W. A. Black and J. E. DeWolf; treasurer, H. G. Bauld.

A LICENSE has been granted the Norton Manufacturing Company, of Illinois, U.S.A, to manufacture and sell sheet-metal goods and other articles in the Province of Ontario.

MCOUAT & MCRAE, machinists, Lachute, Que., have put on extra hands to fill an order for six pulp grinders and other machinery for Hamelin & Ayres' new pulp mill in that town.

A. WATSON, A. and Wm. McLachlan, A. H. Deike, Elizabeth J. Deike and J. Mitchell, Guelph, Ont., have applied for incorporation as "The Guelph Acetylene and Gas Generator Co., Limited."

THE officers elected for the year by the South Kootenay Board of Trade, at Nelson, B.C., are: President, John A. Turner; vice-president, H. J. Evans; secretary-treasurer, H. B. Thompson.

THE officers of the Chatham, N.B., Board of Trade for the year are: W. S. Loggie, president; W. B. Snowball, vice-president; J. D. B. F. Mackenzie, secretary; George Stothart, treasurer.

WE have received a neat little calendar from the McLaren Belting Co., of Montreal and Toronto, accompanied by a handy price list of belting, card clothing, studs, pulleys, and the various other articles dealt in.

THE city of Belleville, Ont., is inviting correspondence with manufacturers desiring to establish new industries or extend existing ones. Liberal terms are available for substantial firms desiring a location in Belleville.

JOHN BENN, proprietor and manager of the dynamite works at Tweed, Ont, has sold out to Daniel Smith, Montreal. The new firm will be known as the Ontario Powder Works. Mr. Benn will be retained as manager.

THAT the goods manufactured by the Goldie & McCulloch Co., Limited, Galt, are gaining a wide reputation, is evidenced by the fact that the company has recently received an order from a London, England, firm for blocks and tackle.

THE sheriff took possession of the Toronto Junction Foundry Co., Limited, a short time ago, which was incorporated last year with an authorized capital of $24,000. Of this sum $8,700 was paid, but this proved insufficient. The business will be wound up.

LETTERS patent have been issued to J. Goodison, J. F. Lister, C. Mackenzie, E. F. Goodison and W. T. Goodison, Sarnia, as the John Goodison Thresher Company of Sarnia, Limited, to manufacture and sell threshing machines and agricultural implements, with a capital stock of $90,000.

THE company which is negotiating with St. John, N.B, for starting a pulp factory at Mispec, near St. John, was registered at Edinburgh, in December. The directors are:—J. Galloway, W. Dixon, F. Wallace, P. Grosset and C. Anderson, all of Scotland. Registered office, Royal Bank Buildings, Leven, Fife.

BOWMANVILLE, Ont., will buy a fire engine.

WALLACEBURG, Ont., is to have a new $8,000 hotel.

THE Woodstock, Ont., town council will buy a fifteen-ton road roller.

LONDON, Ont., erected new buildings last year to the value of $270,000.

PORT COLBORNE, Ont., voted approval of the waterworks by-law last month.

THE new water system at Cowansville, Que., was satisfactorily tested recently.

THE Canada Switch and Spring Co., Montreal, has installed a Bessemer steel plant.

THE Hamilton, Ont., Waterworks Department shows a surplus for last year of $5,000.

SHELDON & SON, Aylmer, Ont., iron founders, are moving into larger premises, it is reported.

THE Berlin, Ont., Waterworks Company is going to put in a system in Waterloo, Ont., this season.

C. N. ROBERTS has been engaged to take charge of the waterworks pumping plant at Renfrew, Ont.

A GOOD roads convention was held at Sweetsburg, Que., last month, which was addressed by A. W. Campbell, the Ontario road instructor.

ELIAS ROGERS has been elected president of the Toronto Board of Trade by acclamation, and A. E. Kemp vice-president, also by acclamation.

THE Graham Nail Works, Toronto, has installed recently a 35 h.p. gas engine, which it is estimated will effect a large annual saving in running expenses.

EIGHT new elevators have been built on the line of the Calgary and Edmonton Railway in one hundred miles north of Red Deer during the past season.

HOUSE & FISK, Lansing, Mich., are corresponding with Galt Ont., about starting the manufacture of the Patterson acetylene gas generator in that town.

NEGOTIATIONS between the refiners of Petrolia and a group of English capitalists, looking towards the consolidation of the refining interests, are still going on.

W. J. KNOWLES, late vice-president of the Goold Bicycle Company, Brantford, Ont., is organizing a new company for the manufacture of bicycles in Canada.

THE Kerr Engine Works, Walkerton, Ont., recently supplied the waterworks commission, Kaslo, B.C. five fire hydrants, nine 6-inch gate valves, four 3-inch gate valves, thirteen valve boxes.

THE tender of the Dominion Bridge Company for the erection of a new iron bridge over the St. Francis, in place of the old Aylmer bridge, Sherbrooke, Que., was $8,386; weight, 284,000 lbs. Accepted.

THE Chatham, Ont., Dredging Company has been notified by the township of Tilbury North that it has been awarded a contract for dredging Trembly Creek, which will amount to $4,000.

As a result of favorable votes, last month, on by-laws to establish a House of Refuge in Bruce County, carried in Lucknow, Walkerton and Kincardine, such a building will no doubt be erected at an early date.

THERE was recently cast at the Londonderry, N.S., Iron Works, a pipe 42 inches in diameter, made of Nova Scotia iron, and weighing nearly three tons. It was ordered for a culvert on the P. E. Island Railway.

THE sources from which Rossland, B.C., proposes to secure a water supply are Stoney Creek, 470 gallons per minute, from an elevation of 375 feet, distance 4 miles; and Murphy Creek, 500 gallons per minute, from an elevation of 600 feet, distance 10 miles.

THE Maritime Sulphite Fibre Co. have completed a mill on the Canada dock, Chatham, N.B., for cutting, barking and preparing wood for the grinder in the pulp mill, and another similar mill is in course of construction. In operation each mill will employ about 25 hands.

IT has been decided to liquidate the Taylor Iron and Steel Co., Limited, Montreal. The company was chartered about a year and a half ago to take over the business formerly carried on in boiler tubes and general steamfitters' supplies, by J. & H. Taylor. The liabilities are under $10,000.

INCORPORATION has been granted to The Hamilton Acetylene Gas Machine Company, Limited, with a capital stock of $45,000, and these members: G. S. Bingham, Mrs. A. Seguin, F. A. Carpenter, W. R. Moore and S. D. Biggar, of Hamilton, and J. D. Forsyth, of Claremont, Ont.

AN English syndicate has been formed, it is said, to erect palatial hotels at Halifax, Montreal, Ottawa, Toronto and Niagara Falls. The plans also include a big hotel in London, England, that will cater to the colonial trade.

LETTERS patent have been issued to R. McDougall, Thomas McDougall, A. J. Oliver, R. McDougall, Jr., and Elsie McDougall, Galt, Ont., as the R. McDougall Company, Limited, to manufacture and sell hot-water, steam-heating and ventilating apparatus, and carry on business generally as iron founders.

THE Kingston and Montreal Forwarding Company has closed a contract for the construction of an elevator at Coteau Landing of a capacity of 500,000 bushels. The contractor is under heavy bonds to have the elevator ready to receive grain not later than May 10th next. There will also be a large warehouse in connection with the elevator.

C. H. TAYLOR, of the Taylor Hydraulic Air Compressor Co., Montreal, has returned from British Columbia, where he arranged for installation of a 500-h.p. plant, at Ainsworth, B.C. Contracts have been let and the work is rapidly progressing. The power is to be sold to mines within a radius of five miles of the compressor at a low rate.

THE gifts of W. C. McDonald to McGill University now amount to close on a million and a half dollars. The equipments of Mr. McDonald's three buildings are the most modern, as well as the finest, in America, and the endowments are such as contemplate their remaining always modern. These gifts make Montreal the envy of other cities.

C. H. ACTON BOND and Sanford Fleming Smith are the members of a new firm of architects in Toronto. Messrs. Bond and Smith have had several years' experience in New York, and are specially well qualified by their experience in that city to undertake the steel construction which is now so much employed in large buildings. The firm has at present four residences in Peterboro, Ont., and one in Ottawa under contract.

WE have received from P. S. Gibson & Sons, of Willowdale, Ont., the engineers of the Township of York, their report on the state of public works in the townships of Coleman, Todmorden, Deer Park, Bracondale, Swansea, Lambton Mills, Mount Dennis, North of Weston, Downsview, etc. It deals with needed extensions in sidewalks, the condition of those long in use, and lighting, and contains a pronouncement by the township solicitors on the responsibility for damage done by traction engines.

A. ROBILLARD, St. Andrews, Que., is the inventor of a new system of operating swing bridges for canals, railways, etc. It dispenses with the central shaft, or axle, as well as with the wheels. Instead of these, Mr. Robillard introduces a ball-bearing system. The surface friction is thus reduced to a minimum, requiring one man to operate it where it now requires several. Another feature of the invention is an automatic system of opening and closing the gates at the entrance to the bridge. As soon as the bridge commences to swing open, the gates close, and the movement which closes the bridge causes the gates to open.

THE fact that iron is being exported from the United States to Europe is said to be influencing the proprietors of the Nova Scotia Iron Works at Ferrona, in Pictou county, to discuss the removal of the works to Louisburg, Cape Breton. The original object in locating the works at Ferrona was to be alongside the deposit of ore supposed then to exist there, and also to be near coal and limestone. But the deposits of ore were not extensive, and now nearly all the ore used comes from the company's ore beds in Newfoundland. It is further said that Pictou county coal is not so well suited for smelting as is Cape Breton coal. In fact, the company made practical tests of the latter, with the result that they ordered something like 10,000 tons. This had to be taken from Louisburg to Pictou Landing by water, and then to Ferrona by rail. By locating at Louisburg the company would be alongside the kind of coal they require, and would be saved the haul by rail of their ore from Newfoundland. They would also have an advantage over Alabama competitors in the matter of freight, the latter being handicapped with a haul of several hundred miles to the seaboard and a longer ocean journey. At the meeting of the company held at Halifax a short time ago, the project was discussed, we are told, in all its bearings. The authorities of Sydney, having heard of the possibility of removal, made proposals that Sydney, not Louisburg, should be chosen, because it offers advantages in point of situation, railway and shipping facilities, etc., fully as great as Louisburg, while a proposal of exemption from taxation, or cash bonus, has been made by resolution of the town council, to any "coal mining companies or other companies which will locate their workshops, offices and shipping piers on the peninsula of Sydney." If it should prove to be the intention of the company to locate their works in Cape Breton, with the object of making pig iron for export abroad, it would seem to be well placed and circumstanced for such an enterprise, either at Sydney or at Louisburg.

JOHN JOHNSTON, a lumberman of Orillia, is building a planing mill at Ahmic Harbor, Ont.

THE Mac Machine Company has decided to remove its plant from Trail to Rossland, B.C.

THE shareholders of the nail factory, St. John's, Nfld., received a dividend of 6 per cent. on last year's business.

THE G.T.R. foundry, employing about 75 to 100 men, in Hamilton, Ont., has been closed down; part of the plant will be removed to Montreal.

S. CARSLEY, dry goods merchant, Montreal, is going to rebuild the old Canada Life building, St. James street, Montreal, in white marble as a store.

THE officers of the Berlin, Ont., Board of Trade for the year are: President, C. K. Hagedorn; vice-president, G. V. Oberholtzer; secretary, J. S. Hoffman.

AT the annual meeting of the Brantford, Ont., Board of Trade, Henry Cockshutt was elected president; T. H. Preston, vice-president; George Hately, secretary-treasurer.

A WRIT has been issued against the Welland, Ont., council of 1897, by the Waterous Engine Works Co., claiming damages for the non-fulfilment of the contract to purchase a fire engine.

G. BROWN, Westmeath township, Renfrew county, Ont., has been awarded the contract for building the bridge across the Colounge River, near Colounge, Que. The contract price is said to be $6,000.

THE building of the Simcoe County House of Refuge was awarded to A. Tessier, of Penetanguishene, for $14,966, exclusive of plumbing and heating. J. R. Eaton's tender was $18,914, without the plumbing.

CORNWALL, ONT., and Hull, Que., are in correspondence with the Toronto Rubber Company, which proposes to remove its Port Dalhousie factory to some locality where a water-power of three or four hundred horse-power can be obtained. The company pays out about $100,000 per annum in wages.

C. W. YOUNG, who has been president of the N.B. Granite Works at St. Stephen, N.B., for the past several years, has bought the business, and will run it under the same name. He has also bought the shot tower, which is situated near the mill, in which the shot necessary for the work of polishing the stone is manufactured.

THE engineering trades strike in England was ended at a meeting of the committees representing the federated employers and the allied trades unions on January 29th, when the result of the ballot accepting the employers' terms was communicated, and a formal agreement embodying the terms of the settlement was duly signed and arrangements were completed for a simultaneous resumption of work in all the federated workshops.

No. 13 St. Sacrament street, Montreal, in which the Montreal Stock Exchange is located, is to be rebuilt. David Ogilvie is the architect in charge, and the Dominion Bridge Company has already been awarded a contract to put a steel frame in the building, which will receive an additional story or two. The new walls and floors will be of marble and tiling. The woodwork is to be of white ash, and the elevators will be electrical. There will also be an ornamental iron stairway.

SIX important amendments to United States patent laws came into force on January 1st, 1898, which in substance are as follows: 1st. A patent will not be granted to an applicant if the invention has been patented or described in any printed publication in any country before his invention or discovery thereof, or more than two years prior to his application. 2nd. A United States patent will not be granted to an inventor who has obtained a foreign patent, unless his United States application be made within seven months of the date of filing of the foreign application. This clause, it will be noted, only applies when the foreign patent has actually issued, and is not merely applied for. 3rd. The application must be completed and prepared for examination within one year after the filing of the petition, and must be prosecuted within one year of the date of any official action thereon. 4th. The prior issue of a foreign patent will not now limit the United States patent to expire at the end of the legal term of the foreign patent. 5th. If an assignment, grant or conveyance be duly acknowledged before a proper officer, the certificate of such acknowledgment under the hand and seal of such officer will be *prima facie* evidence of the execution of such instrument. 6th. No damages can be collected for infringements of a patent occurring more than six years previous to the filing of a bill of complaint or the issuing of a writ. The second amendment referred to is of immediate importance to Canadian inventors, and it is desirable that they thoroughly understand it, so that on one hand they may make their United States applications in due time, and on the other be prepared to meet the attempts of unscrupulous United States firms to entice them into making worthless United States applications.

THE Page Wire Fence Co. has received an order from the Atlantic and Lake Superior Railway Co. for two hundred miles of standard railway fencing. This amount of fencing will make about thirty car loads.

Electric Flashes.

M. B. QUINN, Windsor Mills, Que., has built a flour mill which is operated by electricity.

IT is stated that the Royal Electric Co., Montreal, will shortly absorb the Montreal Gas Co.

THE Canadian General Electric Co. has sent out to its friends a very handsome wall calendar showing a view of the works at Peterboro, Ont., and gold background.

COMMUNICATION by the new cable between Turk's Island and Halifax, by way of Bermuda, was established Jan. 17th, and business despatches are now being transmitted.

THOS. EDISON, JR., has planned an apparatus for generating electricity from the wave motion of the ocean by means of floats which would operate an air compressor.

THE corporation of Magog, Que., has placed an order with the Canadian General Electric Company for a 2,000-light alternator of their single phase, revolving armature compounded type.

THE Northey Manufacturing Company, of Toronto, has increased the capacity of its incandescent lighting plant recently purchased from the Canadian General Electric Company from 250 to 350 incandescent lamps.

THERE is a move on foot to get an electric railway service for the Island of Orleans, near Quebec. It is reported that a charter will be asked for at the next session to construct an electric railway around the island. The power is to be obtained from the Montmorency Falls.

MUCH surprise has been expressed in the trade because Hon. J. I. Tarte let the contract for four Westinghouse 40 horse-power electric motors, and four Worthington pumps, one of each of which are to be placed in the East, West, Centre and Langevin blocks of the Parliament Buildings, at Ottawa, to Ahearn & Soper, Ottawa, for $30,000, without calling for tenders.

THE street cars in Toronto have been equipped with a new appliance which does away almost entirely with the use of the immense snow sweepers. The digger is a contrivance that attaches to the machinery of the car, and by pressure from the motorman, digs down into the groove of the rail and cleans out the snow. It is the invention of Foreman Power of the Toronto Railway Company's car building shops.

IT is understood that Engineers Keating, Toronto; Pearson, New York, and Wanklyn, of the Montreal Street Railway, have visited the new Chambly works with a view to report upon the feasibility of using that power for the Montreal Street Railway, which, in producing its own power, reaches a rate very nearly $42, or $360,000 per annum, while the Chambly people have, it is said, offered to furnish the company with power at the reduced figure of $32, which would mean a great deal to the shareholders.

WORK was begun on the power house of the Hamilton Cataract Power Company, near Decew Falls, Jan. 8th, and it is being pushed towards completion. The building is to stand within a few feet of the edge of the stream, and above high water level, where the precipitous banks rise nearly 275 feet above the level of the stream. When completed, the power house will be 174 feet in length and 42 feet in width, and the walls 30 feet in height. It is to be constructed throughout of steel, faced with brick, and have concrete floors. The stone is quarried on the spot, and the cement is supplied by Battle Estate, Thorold. Angus McDonald & Co., Hamilton, are contractors for the construction of the canal, power house, etc.

THE Guelph Light and Power Company has decided to replace the arc lighting machinery for supplying the street circuits with the latest and most approved machinery for the purpose, and has placed an order with the Canadian General Electric Company for an 80-light Brush arc machine, equipped with automatic regulator. These large Brush machines, of which eight having a capacity of 125 lights each, have been purchased by the Toronto Electric Light Company—four of the same size by the Montmorency Company of Quebec, and four for direct connection to synchronous motors by the Lachine Rapids Hydraulic and Land Company—are believed to represent the successful development of arc lighting machinery along the lines which have been established as approved practice in direct current and alternating work.

Now that the waterworks are assured for Port Colborne, Ont., an agitation is on foot for electric light.

MANAGER LEATHER, of the Hamilton Radial Electrical Railway, says his line will be extended to Bronte by May 1. The railway has been built into Burlington.

THE Toronto & Hamilton Electric Co., successors to Kay Electrical Mfg. Co., reports that among recent sales are the following twenty machines to different parties: Hallman & Co., Berlin, one 12 h.p. motor; Toronto Cold Storage Co, one 50 lt. dynamo; *Journal* Printing Co., St. Catharines, Ont., one 5 h.p. motor; Geo. Membery, St. Catharines, Ont., one 3 h p. motor; Toronto Ornamental Iron Co., one 1,000 gal. plater; Meakins & Co., Hamilton, one 1 h.p. motor; R. N. Grundy, Guelph, one 200 gal. plater; Berlin, Ont., Felt Boot Co., one 150 lt. dynamo; Victoria Wheel Works, Galt, Ont., one 150 lt. dynamo; Messrs. A. R. Woodyatt & Co., Guelph, Ont., one 250 gal. plater; J. C. Harris, Toronto, one 7 h.p. motor; McKinnon Building, Toronto, one 2 h p. and one 10 H. & P. direct connected motors and controllers; Garrioch & Goddard, Ottawa, one 2 h.p. and one 4 h.p. motor; Berlin Shirt and Collar Co., one 4 h.p. motor; D. W. Karn & Co., Woodstock, one automatic organ blowing machine, besides several machines in Victoria, B.C., and Woodstock, N.B.

A REPORT of the Commissioner of Inland Revenue dealing with the official inspection of weights and measures, gas and electric light, recently issued, contains sundry items of general interest. The progress which has been made in lighting by electricity is well illustrated by the statement that there were one hundred and eighty-seven electric light companies registered under the Inspection Act during the year ending on the thirtieth of June, 1897. The first in importance, measured by the number of lamps in use, and reckoning each arc light as equal to ten incandescent, is the Royal Electric Company, of Montreal, which heads the list with 1,450 arc and 58,000 incandescent lights, or a total equivalent to 72,500. The Ottawa Electric Company comes next with 550 arc and 57,240 incandescent lights respectively, or a total of 62,740. Third on the list is the Toronto Electric Light Company, with 1,400 arc and 45,000 incandescent lights, or a total of 59,000. The Montmorency Electric Power Company, of Quebec, follows with a total of 17,080, below which the figures decline rapidly. Contrary to what might reasonably be expected, only one company, and that with an evidently very limited patronage, is registered at Winnipeg. During the year 3,208 electric light meters were presented for verification. Of these, 3,111 were passed, "as coming within the error tolerated by law," 698 are tabulated as actually "correct," and 1,633 others of these "verified" meters are classed as "fast."

FROM the plant which the West Kootenay Electric Light and Power Company is erecting at Bonnington Falls, B.C., it is expected that transmission of power to the Rossland mines will be commenced early in February. Robert Jamieson is general manager and engineer for the company. L. A. Campbell, engineer of the Canadian General Electric Company, is erecting the generators at the power plant. Bonnington Falls, where the power house is located, lies about 11 miles below Nelson, B.C., on the Kootenay River. Water is conducted to the reservoir from the river by a canal 22 feet deep, cut out of the rock for a distance of 640 feet. The dam, which is of concrete, is 32 feet high and 18 feet thick at the base. It extends across the fore-bay, some 54 feet, and is reinforced on the sides by abutments of concrete. The average rise of the Kootenay River is 22 feet, and the highest flood on record was 32 feet above the minimum height of the stream. From the fore-bay the water is carried to the turbine wheels by three steel pipes, two of which are nine feet in diameter, while the third is a foot larger. At present only the two former tubes will be used. The wheels, which are two in number, are of the twin horizontal type, manufactured by the Stillwell-Beirce-Smith-Vaile Company of Dayton, Ohio, and will develop 1,250 horse-power each, so that their united force is 2,500 horse-power. The turbine wheels are attached direct to the generators. There are two generators, having together a capacity of 2,500 horse-power, made by the Canadian General Electric Company, and of the three-phase revolving field type, wound to generate at a voltage of 1,040. They operate at 180 revolutions per minute. The exciters used in connection with the generators are operated by two separate turbine wheels. The step-up transformers increase the voltage from 1,040 to 20,000. The current is conducted to the sub-station at Rossland over a three-wire line 30½ miles long. The local sub-station, which is situated on the Monte Cristo ground, is equipped with step-down transformers, which reduce the voltage from 20,000 to 2,080 volts. From the sub-station power will be conducted to the various mines which will utilize electricity for motive power. At present it is not intended to use electric drills, but instead it will operate the compressors, and the compressed air will be used throughout the mine as at present. Oliver Durant, the general manager of the Centre Star Mining Co., is the president of the power company.

Personal.

THOMAS J. LOCKE, of the Coast Railway engineering staff, has been appointed assistant engineer at Halifax, N.S.

R. B. MCCREARY has been appointed street engineer of Arnprior, at a salary of 30 cents per hour while on duty.

E. H. KEATING, C.E., city engineer, Toronto, has resigned to become manager of the Toronto Street Railway.

J. WOODMAN, Winnipeg, has been appointed engineer of the C.P.R, western division, *vice* D. A. Stewart, deceased.

JOHN MORROW, of the Machine Screw Company, Ingersoll, Ont., died last week, having been in ill health for two years.

W. J. SPROULE, assistant engineer to the Harbor Commissioners office, Montreal, has been elected mayor of St. Lambert, Que.

SIR CHARLES HUTTON GREGORY, the well-known engineer, and a former president of the Institution of Civil Engineers, Great Britain is dead.

H. W. TRUE has been appointed manager of the People's Heat and Light Co., Halifax, in succession to Peter Young, who goes to Pittsburg, Pa.

THOMAS MESTON, secretary-treasurer of the Hamilton Bridge Company, died at his home in Hamilton, Ont., a short time ago. He was 44 years of age.

THOMAS PETES was instantly killed at Steinhoff & Gordon's stave and hoop mill, Wallaceburg, Ont., a short time ago, by being caught in a shaft. The body was terribly mangled.

ST. ANDREW'S SOCIETY, Dundas, Ont., has been reorganized, John Bertram president. The president has been given the custody of a genuine Burns' snuff box of mahogany wood.

ON December 22nd, Harry A. Moore, B.A., superintendent of the Electric Light and Power Company, Trenton, Ont., was married to Miss Charlotte Greenwood, of Whitby, Ont.

R. EVANS, foreman of the Niagara Falls Metal Works machine shop, has gone to London, Eng., to take a position at $2,000 per annum. The metal works are being worked overtime at present.

T. F. FOLEY, of the firm of Holliday & Foley, of the Stratford, Ont., Bridge and Iron Works, extensive bridge builders, died recently of scarlet fever. He was an esteemed and popular young business man.

F. G. B ALLAN, superintendent of cement works, Napanee Mills, Ont., had a very severe shaking up lately by falling into the mixer. When rescued he was holding on to one of the arms of this tremendous machine.

P. A. DICKENSON, for a number of years head electrician of the Brantford, Ont., Electric and Operating Co., is leaving the city to engage in mining operations with the Mineral Point Mining Co., of Ashcroft, B.C.

T. MATTHEWS, while at work at the axle works, Woodstock, recently, met with a painful accident. A piece of steel flew from the hammer and struck him on the arm between the elbow and the wrist. It lodged about two inches deep in the flesh.

CAPT. WM. HALL, the superintendent of the Le Roi mine, Rossland, B.C., was killed, January 5th, by falling down the main shaft from the surface to the six hundred foot level. The body was terribly injured by the fall, and the remains were hardly recognizable.

DANIEL BOWERMAN, proprietor of Hallowell mills, about two miles east of Picton, Ont., was found dead in his mill last month. Marks of the cogs of a wheel were found on the side of his head. The wheel is supposed to have struck him while engaged in fixing the machinery.

ROBT. HEWITT, of the firm of R. Hewitt & Son, Phœnix Foundry Co., died at Markham Ont., a short time ago, of pneumonia, after a short illness. He was born in Cumberland county, England, in 1818, settled in Markham in 1855, and has conducted the business of the Phœnix Foundry for 30 years.

W. J. OLIVER, a pattern maker at the pulp mills at Sault Ste. Marie, Ont, crossed to the United States side one evening recently to attend a religious service. In going home he fell over the old Michigan canal bank to the lock chamber, a distance of fifty feet, and was killed. His family lives at Carleton Place, Ont.

FRANK RIDDELL, the foreman of the Imperial Oil Co.'s paraffine department at Petrolea, Ont., was presented a short time ago with a gold headed walking stick as a slight token of esteem by the employes. F. Ireland read the address, and W. Wilkinson made the presentation, while Bruce Dunlop acted as chairman.

An application for the city engineership of Toronto has been received from Stewart Howard, C.E., Montreal, who was formerly resident engineer in Toronto for the Northern Railway, and subsequently, while in the service of the C.P.R., designed and constructed the western entrance of that road into Montreal.

Arthur F. White has gone from Toronto to England. For the past two years Mr. White has been mechanical superintendent of the Hyslop tricycle factories, and was formerly lecturer in machine design on the Toronto Technical School staff. Mr. White has been engaged by a large firm in London, Eng., to install and operate a surveying plant, which he takes over with him from Hartford, Conn.

Jno. Hunter, brassfounder, Halifax, N.S., died last month. He was about 78 years of age and had spent about half a century in Halifax. For a good many years he carried on business on Sackville street, with his son Edward, but he first opened on Hollis street with Robert Wright as his partner. The deceased, who was a native of Glasgow, Scotland, was a citizen much respected by all classes, and his death will be deeply regretted.

George E. Drummond, of the Canada Iron Furnace Co., has returned from the old country, and one result of his trip is that considerable shipments of Canadian iron will be made to Great Britain and Germany. It is very gratifying to know that the superior qualities of Radnor Forges iron for special purposes are now acknowledged abroad as well as in Canada. Mr. Drummond confirms the reports that Canada now occupies a larger place in the mind and heart of Great Britain than it ever did before, and the next few years should see a large development in Anglo-Canadian trade.

The popularity of F. P. Brothers, late chief of construction of the Montreal Street Railway, was demonstrated shortly before he left for Jamaica, where he will superintend the building of a new line, by a banquet tendered him. The general manager, F. L. Wanklyn, presided, and covers were set for over a hundred, which included representatives from all the departments. The speech of the evening was made by Supt. McDonald, who, in the course of his remarks, said that he would use a strong and more electric expression concerning Mr. Brothers, by stating that their best affections had been permanently grounded by the magnetic currents of his well known business tact, his ability and genial friendship. The superintendent, amid great enthusiasm, then presented Mr. Brothers with a handsome traveling bag. Mr. Brothers, whose health was drunk with musical honors, received a great ovation. Short congratulatory speeches were also made by Messrs. Blackwale, president of the Canada Switch Co., J. Ross, Major Laurie, R. Chapman, John Garth, Landers, Carter and Swan.

Marine News.

Lunenburg, N.S., is to have a marine railway. The boiler, engine, etc., are now on the ground.

Thomas Gale & Sons, Cumberland Bay, N.S., are building a schooner 77 feet long. John Parker & Sons, of the same place, are also building a woodboat, keel 61 feet.

The British Columbia Iron Works, Vancouver, B.C., have contracted to deliver two river steamers for the Hudson Bay Company, one in March, and the second on April 15th.

The Albion Iron Works, Victoria, B.C., have contracts for machinery for a number of vessels, including those for steamers which the C.P.N. Co. will place on the Yukon and Stickeen rivers.

As it will cost $20,000 to repair the steamer "Rosedale," its owners have abandoned it to the underwriters, who will hand it over to the Donnelly Wrecking Co., in payment for the work of saving the boat.

The first of the officers of the new Richelieu and Ontario Navigation Company's steamer "Toronto," has been appointed in the person of William Black, chief engineer of the steamer "Hamilton," who is to be chief engineer of the new boat.

The Polson Iron Works Company is preparing plans for a yacht for Timothy Eaton, Toronto. The boat will be 55 feet long by 8 feet beam, 3 feet 6 inches draught, and will run 16 miles an hour. It will have a steel frame and wood planking, and a triple expansion engine and tubular boiler. The yacht will be the handsomest boat on the Muskoka lakes.

Warren McCurdy, of St. Andrew's, N.B. has invented an electrical log. It is claimed to be accurate, not varying three-tenths between different trips recorded by it from light to light. The rotary log, instead of turning the line as in ordinary taffrail logs, communicates by a little cable with the steamer and registers in the captain's room. There can be dials, worked from the same log, in any part of the steamer.

A public meeting in Goderich, Ont., recently passed resolutions in favor of running a line of first-class steamers the coming season from Windsor to Sault Ste Marie, calling at all the ports along the route.

Citizens of Annapolis, N.S., are forming a company to build a freight steamer to carry freight between Annapolis and St John, N.B., calling at Bridgetown, Granville Ferry, Clementsport, Bear River and Digby.

Col. Anderson, of the Marine Department, Ottawa, was in Parry Sound not long ago, and visited Depot Harbor and Kilbear Point to inspect the locality for the Department with a view of building a new lighthouse at Kilbear, and range lights west of Kilbear and Depot Bay.

We have received a nicely got-up catalogue of boats fittings and appurtenances, to be had of the builder, Harold B. Rye, of Peterboro, Ont. He is perfectly familiar with all the details in the construction of a great variety of small boats, including family, pleasure and fishing skiffs; paddling, cruising and racing canoes; cat boats, etc. Those who are interested in the subject of prospecting canoes will do well to consult this catalogue, which gives the prices of many different styles.

The J. Bruce Hanly Engine Works, Midland, Ont., are building a 7 x 14 x 10-inch steeple compound engine for the Muskoka Navigation Company, Gravenhurst, and a 13 x 26 x 20-inch compound engine for James Playfair and Capt. Burke, who are themselves building the hull here for a general purpose tug. They are also overhauling a 18 x 36 x 32-inch steeple compound engine, re-boring cylinders, putting in new pistons, valve rods, etc., besides new brasses throughout. This is for the James Playfair Company, which is building the hull in their Midland shipyard, and intend her for open lake log towing.

Charles W. Ross, of the Railways and Canals Department, Ottawa, has secured a relic of some interest. It is a section of the mitre sill of an old canal lock built in 1780 by the Hudson Bay Company. The oak timber has therefore been for considerably over a hundred years under water, and yet is firm and solid. The section has not been touched by worms. The canal, which was half a mile in length, was built by the Hudson Bay Company to get past the Cascade Rapids in the St. Lawrence, but long since fell into disuse. It has a raise of about 13 feet, and contains three locks. The construction work was done by Col. Colter Mann.

Application will be made to the Parliament of Canada, at its next session, for an act to incorporate the Lake Superior and Rocky Mountains Navigation Company, to construct canals, from Lake Superior near Thunder Bay, thence following a chain of lakes and rivers across the height of land to Rainy Lake, and by way of Rainy River to the Lake of the Woods; from the Lake of the Woods along Rousseau River to the Red River; thence along Red River, Assiniboine River, Lake Manitoba and Lake Winnipegosis to Cedar Lake on the Saskatchewan River; or in the alternative from the Lake of the Woods by way of Winnipeg River, Lake Winnipeg and the Saskatchewan to the last mentioned point; and from Cedar Lake on the Saskatchewan River and Bow River to Calgary, in Alberta, and along its northern branch to Edmonton.

F. M. Rattenbury and others have given the contract to J. Stephens, of the Clyde shipyard, Victoria, B.C., for three new stern-wheeled steamers to ply on Lake Bennett. These vessels are to be ready for shipment north within thirty days. All three vessels will be stern-wheelers, 80 feet long, of 16 feet beam and will have a draught of 18 inches when laden. They will be wooden boats and the machinery will be supplied by the Albion Iron Works. The contract for taking the hulls of the vessels into the lake will be distinct from that of either the furnishing of the machinery or the building of the hulls. A fourth steamer to be built at the Clyde yard will be a twin screw which J. Stephens has the contract from a Tacoma firm for constructing. It is intended for Teslin Lake.

A settlement has been effected between the parties in the suit of the Toronto Ferry Company for an injunction to restrain the city of Toronto from improving and maintaining the embankment protecting the intake pipe across the bay. This embankment caused stagnant water to accumulate in front of the Ferry Company's property and greatly depreciated it. By agreement the northern boundary of the Ferry Company's property is to be extended by means of piling to the conduit embankment opposite. The waterworks breakwater is to be extended southerly to the Ferry Company's property, and the area thus enclosed is to be filled in by the city with the sand pump. The city must undergo the expense of the piling, but the company must allow the city to use such piles on the eastern side of its property as become unnecessary by the proposed changes. The land thus made is to be used by the company in connection with their summer resort free of charges until the lease expires in the spring of 1901, when a renewal rent on a valuation basis shall be paid by the company. The company

on their part abandon all claims against the city for the silting up of their boat channel to the Point. They also forego all claims for past damages of any nature and consent to the issue of the order applied for to the Dominion Government, giving the city legal right to maintain the present embankment. Each party to the suit must sustain their own costs.

THE "Castilian," now building for H. & A. Allan, which will take her place on the Liverpool-Montreal route next spring, will have a registered tonnage of 8,800; her length will be 520 feet, and her beam 58 feet. She will have a speed of about fourteen and a half knots per hour, and passenger accommodation for 150 first cabin, 120 second cabin, and 800 steerage. The saloon, state rooms, and smoking room will be all located on the spar deck. The music room, which will be located on the bridge deck, will afford accommodation for a large number of passengers. The smoking room is arranged with easy chairs, divans and small tables for card parties. Besides her passenger accommodation, the "Castilian" will carry a large amount of freight. The freight accommodation will include refrigerators for perishable goods, and will be arranged so as to give different temperatures in the separate chambers.

Railway Matters.

THE T., H. & B. have given the contract for repairing their rolling stock to the Waterous Company, Brantford, Ont.

APPLICATION is made to the Dominion Parliament for a charter for a railway from Hull, Que., or Montreal to Rupert Bay.

THE C.P.R. has closed a contract for fifteen compound locomotives. They will be heavy and of the most modern design.

H. R. RIDOUT & Co., railway supplies, Montreal, have dissolved partnership, and a new firm has registered, composed of Edward H. Seale.

W. RUSSELL & Co. have been given the work of building the Pembroke Southern Railway from Pembroke, Ont, to Golden Lake, where it makes connection with the O.A. & P.S.R.

A DEPUTATION consisting of Hon. R. R. Dobell, J. G. Scott and others waited on the Local Government recently, asking a charter to build a railway from Roberval to St. James' Bay, a distance of 300 miles, through a very rich country of the Lake St. John district. The assistance they ask is a grant of land.

A BILL to incorporate the Niagara Tramway Company, with a capital stock of $50,000, has been introduced in the Assembly of the State of New York. It is the intention of the company to string a wire across Niagara Falls and run a tramway from one side of the river to the other. It is designed to carry passengers and freight.

GEORGE GOODERHAM, W. R. Brock, Robert Davies, Hon. L. M. Jones and J. Herbert Mason, are members of the committee of disinterested and public-spirited citizens whom Mayor Shaw, of Toronto, acting upon the suggestion in the letter of T. G. Blackstock to *The World*, has induced to consent to handle the question of the city building a railway from Toronto to James' Bay. The question whether the present lines of the C.P.R. or the G.T.R. are to be utilized, or an entirely new line built, is the most important one the commission has to decide.

A DEPUTATION, representing the Commonwealth Mining Company, consisting of S. O. Shorey, J. C. Holden, Senator Thibaudeau, Montreal; J. R. Barber, Georgetown, Ont.; C. Riordon, Toronto; J. B. Powell, Nelson, B C., and others, waited on the Dominion Government recently. The company has a scheme for a stage line between Edmonton and Dawson City, in the Yukon, which they say can be traveled in about twelve days. The distance is about 1,500 miles. They propose to construct a trail all the way from Edmonton, and ask the Government to guarantee interest on bonds to the extent of $2,000 per mile for 1,500 miles.

THE Restigouche & Western Railway has completed arrangements for building the first 20 miles of the line. Malcolm & Ross are the contractors, and C. L. B. Miles is chief engineer. The road will be from the I.C.R., at Campbellton, N B., to the St. John River at Grand Falls or St. Leonards, at either of which it connects with the C.P.R.; at St. Leonards also with the Bangor & Aristook Railway. By bridging the Restigouche at Campbellton, it will connect with the Atlantic & Lake Superior to Gaspe. There will be 110 miles to build, through heavy timber, sprnce and cedar, in abundance, and some fine tracts of farm lands, on ridges covered now by a wealth of rock maple.

THE Canadian Pacific Railway and Auguste Heinze have come to terms, and the agreement is that the Trail smelter, the railway from Robson to Trail, the short line from Trail to Rossland, and the lands received from the British Columbia Government as subsidies, are handed over to the Canadian Pacific Railway for the sum of $800,000 The narrow gauge from Rossland to Trail will at once be widened to the standard by the new owners, who will also make the grades much easier. The line from Robson to Trail is a standard gauge, is well built, and can be operated at once in connection with the system to which it now belongs.

THE Ontario Government voted the following railway bonuses at the last session: To the Ontario and Rainy River Railway, from a point at the westerly end of the 165 miles heretofore aided to a point at or near Fort Frances, a distance not exceeding 40 miles, a cash subsidy of $3,000 a mile—$120,000. To the Pembroke Southern Railway, between Pembroke and Golden Lake, from a point in the north-east part of the township of Alice to the north-eastern boundary of the said township, a distance of 3½ miles, a cash subsidy of $3,000 a mile—$10,000. To the Irondale, Bancroft and Ottawa Railway, from a point 45 miles from Irondale, at the end of the portion of the railway to which aid was granted in 1896, and thence due east for a distance of 10 miles, a cash subsidy of $3,000 a mile—$30,000. To the Bay of Quinte Railway, for such extension or branches of its projected and authorized line of railway north of the village of Tweed, as will not exceed thirty miles in all, and will enable the said company to connect its existing railway with the iron ore deposits lying northward of the said village of Tweed, in renewal of the amount granted to the Kingston, Napanee and Western Railway in the year 1893, a cash subsidy of $3,000 a mile—$90,000. To the James' Bay Railway, to aid in the construction of ninety miles of the said railway from Parry Sound to a point at or near Sudbury, $3,000 a mile for a distance not exceeding 40 miles ($120,000), and the unearned subsidy of $3,000 a mile for a distance not exceeding 50 miles, which was granted to the Nipissing and James' Bay Railway in 1889, which said unearned subsidy is hereby transferred to the James Bay Railway. (New vote, $120,000; transferred from other road, $150,000)—$270,000.

Mining Matters.

ACTIVE operations are going on at present in the Darling iron mine, Lanark County, Ont. Five thousand tons have already been taken out.

J. H. S. CASS, who is well known to the asbestos trade, is now carrying on business as the Cass Asbestos Mining Co., 97 St. James street, Montreal.

HALIFAX, N.S., papers have recently contained references to the reputed discovery of rich gold fields in Labrador. Some are said to rival the Klondyke in richness, but the reports are without confirmation.

AT a preliminary meeting of the B. C. Association of Mining Engineers, held in A. H. Holdich's office, Rossland, a month ago, a paper on mining laws by G. F. Moncklon, Esq., of Vancouver, was read and discussed.

A NEW oil field promises to be opened at Point Edward, Ont. A test well has been put down, and oil struck at a depth of five hundred and forty-five feet. A company has been formed, and they intend sinking more wells at once.

THE negotiations between Sir William Van Horne and T. G. Shaughnessey, of the C.P.R., and Heinze and Warfield in reference to the purchase by the C.P.R. of Aug. Heinze's railway and smelter in Kootenay, have been practically concluded, and it can be stated that the property in question has been transferred to the C.P.R. interest.

ARCHIBALD BLUE, Ontario Department of Mines, was recently interviewed by Messrs. Ashworth and Murray, of Sault Ste. Marie. They took up a claim in the Michipicoten district, and sunk a fifty-foot shaft. They report having struck a vein eight feet wide and nine feet deep, at a depth of fifty feet, which assayed $32 to the ton.

Two gold bricks from the Saw Bill mine have been on exhibition at Port Arthur, Ontario, recently. Their combined weight is 13½ lbs, and they are the result of 20 days running of the mill, crushing an average of 20 tons per day. Manager Wiley says that putting in a 20-stamp mill will double the output of the mine, and only requires the services of half a dozen more men.

THE following have organized the Northern Yukon-Klondyke Mining Company, Limited: Hon. G. Bryson, jr., Fort Coulonge, Que.; J Gillies, D. Gillies, M.P.P., Carleton Place, Ont.; W. Gillies, of the said place; J B. Fraser, Ottawa; J. B. MacLaren, Buckingham, Que.; A. MacLaren, Buckingham; J. C. Cox, Liverpool, Eng.; J. H. Francis and G. F. Francis, Pakenham, Ont.; J. W. Bryson, Fort Coulonge; W. H. A. Fraser, Westmeath, Ont.; H. Aylen, Ottawa; J. G. MacLaren, Ottawa; J. E. H. Barnet, Renfrew, Ont.

Wm Blackmore, chief manager of the Crow's Nest Pass Coal Co., was in Montreal recently, and will leave for the scene of the company's operations at Coal Creek. Mr. Blackmore has visited the leading mining centres in Canada and the United States, and with the result that the most improved electric coal cutting machinery will be started in the Pass mines. Orders for machinery have already been given out in Montreal, Toronto and elsewhere to the value of $100,000, while the company will erect about fifty beehive cooking ovens at Coal Creek for the purpose of supplying the article to the proposed smelter at Robson, B.C.

H. L. Simmons has purchased twenty acres near Nakusp, B.C., for a smelter site, and has also secured the water rights in that vicinity for the use of the proposed smelter. It will, it is said, be a plant similar in some respects to the one at Trail. It is thought at Nakusp that Mr. Simmons is connected with the parties who are about to erect a smelter at Vancouver. This company, it is claimed, intends to erect smelters at several points in the Kootenay country, and to send the product of these plants to the central refinery, at Vancouver, for separation into the several metals that are in the matte.

The following papers and subjects were presented and discussed at the meeting of the British Columbia Association of Mining Engineers, held in Badminton Hotel, Vancouver, a short time ago: "Notes on Mining Law and its Application to Mines and Mining Districts," by Frank C. Loring, M.E., Rossland; "The Possibilities of Smelting in British Columbia," by Robert R. Hedley, Nelson; "Notes on Southwest Kootenay Ore Bodies," by J. C. Gwillim, B.A. Sc., M.E., Slocan City; "Odd Notes on Mining," by A. H. Holdich, Nelson; "Mining Machinery in the Slocan," by Howard West, A.R.S.M., New Denver.

A shareholder of the famous Le Roi mine received a letter from Rossland recently containing the following details regarding that great property: The mine continues to ship about 200 tons of ore per day to the Northport smelter. Recent returns show that the ore is going about 1.54 ounces in gold, 4 per cent. copper, and 3 ounces of silver; its monetary value being itemized as follows: Gold, 1.54 ounces at $20, or equal to $30.80; silver, 3 ounces at 57 cents, equal to $1.71; copper, 4 per cent. (80 lbs.)at 10¾ cents, equal to $8.60, or a total of $41.11. Estimating the product of the mine at 200 tons per day, the gross value of the ore raised daily is $8,222, or $246,000 per month, which in turn makes the gross yearly product of Le Roi mine $2,959,920.

Reserve—Cassiar District.—Notice is hereby given that the under-mentioned tracts of land are reserved for Government purposes until further notice, viz.: 1. A belt of land, five miles in width, extending back from the shore line of the whole of that portion of Bennett Lake which lies within the province. 2. A belt of land, five miles in width, extending back from the shore line of the whole of that portion of Teslin Lake which lies within the province. 3. A belt of land commencing at a point five miles below Glenora, on the Stikine River; thence up the said river to a point five miles above Telegraph Creek, and having a width of five miles on each side of the said river. —Geo. B. Martin, Chief Commissioner of Lands and Works for the Province of British Columbia.

At a meeting of the Peninsula Mining and Development Company, Limited, held at Windsor, Ont., Jan. 15th, all arrangements were made by the company for their expedition to the Klondyke, which will leave Windsor on February 15th, under the management of Major J. E. Johnson, of Leamington, Ont. The following gentlemen will accompany the Major: C. A. Hugheson, Ouvery; J. C. Burk, Blenheim; M. Toll, Ouvery; J. Coyne, Leamington; B. Noble, Leamington; D. Noble, Northridge; William Johnson, Essex; J. Lickman, Essex; J. C. Myres, Cottam; C. McApe, Cottam; J. Imeson, Wheatley; R. F. Leeming, Kingsville; D. Edwards, Coatsworth; F. Dawson, Coatsworth; Thomas Dancey, Coatsworth; W. Toll, George Lawrence, J. B. Lawrence, Blenheim. The expedition will go by Edmonton, and expects to reach the Yukon district in about two months.

An incident of great interest to the mining district of North Hastings, Ont., took place lately at the Belmont mine, near Marmora, Ont., now being operated by the Cordova Exploration Company, Limited, of Newcastle-on-Tyne, England, which was the official opening of the company's new stamp mill by Miss Grace Carscallen, daughter of A. W. Carscallen, M.P., who formerly owned and developed the property. The opening took place in the presence of a number of persons who had been invited by the general manager, David G. Kerr, Glasgow, Scotland, late superintendent of one of the mines of the same company in Norway, who came to take charge of the property on the 15th of August last. The mill was erected and the machinery built and put in place by the Wm. Hamilton Mfg. Co., Limited, of Peterboro, and speaks well for this firm, who are so widely and favorably known throughout the Dominion as mining machinery manufacturers The construction was under the supervision of Richard Proutt, of Marmora. After the ceremony of opening and inspection was over, and after visiting the Assay Office, which is in charge of George Hardy, chemist, of Newcastle-on-Tyne, a young employee of the Cordova Exploration Company, the party were entertained to a sumptuous repast at the manager's residence.

THE ONTARIO RE-FORESTING COMMISSION.

During the recent session of the Ontario Legislature, the Commissioner of Crown Lands laid on the table the report of the Royal Commission appointed in June last to investigate the subject of "restoring and preserving the growth of white pine upon lands in the Province, which have been cleared or partially cleared by lumbering operations or by fire, and which are not adapted for agricultural purposes or for settlement." The commission consisted of E. W Rathbun, president of the Rathbun Lumber Co.; John Bertram, president of the Collins Inlet Lumber Co.; J. B. McWilliams, superintendent of Forest Rangers; Alex. Kirkwood, of the Ontario Crown Lands Department and Thomas Southworth, Clerk of Forestry.

During the fall and summer the members of the commission visited the townships of Smith, Harvey, Galway and Burleigh, in the county of Peterboro; the territory along the north shore of Lake Nipissing, and down the Vermilion River, in the township of Louise; the country around Thessalon, Algoma Mills and Killarney; the townships of Carlyle and Humboldt, and other points on the north shore of Georgian Bay and in the neighborhood of Georgian Bay. The commissioners also inspected some of the territory on the north shore of Lake Superior and the country along the line of the Port Arthur, Duluth & Western Railway west of Port Arthur, in addition to taking a somewhat extensive trip through the Rainy River country, visiting also portions of the northern parts of Minnesota and Michigan in the United States.

Though the commission has not yet had time to examine minutely enough into local conditions to be able to submit detailed plans for the care and management of the areas visited, yet its investigations have been of a sufficiently technical nature to warrant them in coming to the conclusion that with sufficient areas set aside for the purpose, and with reasonable care and protection of the young and growing timber now upon them, the supply of merchantable timber in the Province of Ontario will be vastly augmented. The commissioners next score lumbermen for the reckless maner in which they have treated our forests. The former apparently limitless forest wealth of the province has led them to be incautious as to the safety of the forests, and the litter they have left lying about has fed the destructive fires that have always followed. These fires have destroyed the original growth, and in many cases paved the way for the springing up of a crop of other varieties more easily propagated. It has been found, however, that where any of the original trees survived the fire and produced seeds, the forest has eventually assumed the characteristics of the growth indigenous to the locality. The widely-entertained theory that the white pine on being cut away is invariably and permanently succeeded by a crop of inferior varieties, was completely disproved by the frequent instances observed in which tracts of flourishing young pine trees are growing up on cut-over land, and the prevalence of the idea can only be accounted for on the ground that fire has in so many cases completely exterminated the pine in all stages of growth. There seems to be no doubt that with the exclusion of fire, and the adoption of more intelligent and provident methods of lumbering, there would be no difficulty in securing a quick and sure production of the varieties of trees desired.

As a rule, after the fires the seeds of the aspen, poplar, birches and cotton woods, which are carried great distances by the wind, soon cover the burned-over area, and a vigorous crop of these varieties springs up, and speedily occupies the ground. In most cases, however, a few pines have managed to survive the fire, and where this is the case their seeds are scattered and soon supplant the poplars and other inferior growths. In looking casually over one of these devastated tracts, the first impression conveyed is that poplar and other deciduous trees form the sole vegetation, but a closer inspection will reveal the presence of a large stock of young conifers, which in time will outgrow and drive the poplars into decadence. The commissioners put forward as an example of what results might be obtained, the township of Burleigh, in the county of Peterboro. The cutting of timber began here 50 years ago, the original forest being chiefly of excellent pine. About 33 years ago a colonization road was run through the township, and since then the lumbermen and the fires started by settlers have devastated the forest on the west side of a stream known as Eel's Creek. The frequent fires have burned over a large part of the soil and killed any pines that may have been left by the lumbermen, so that any national reforestation would be a very slow process.

Now, for the other picture. The east side of Eel's Creek presents an altogether different aspect. Viewed from the Burleigh road, it has the appearance of a thrifty young poplar forest, with a few young pine trees appearing on a level with the poplar. On closer examination, it was found that the young forest was largely composed of red and white pine. It was moreover learned that this portion of the forest had not been visited by fire since twenty-three years ago. The pines will, if protected from fire, soon overtop the poplars and assert the supremacy of their species. The conclusion arrived at was that within fifty years lumbering operations in this locality could be profitably resumed and the larger pine trees taken out, producing timber of a merchantable quality, and giving the younger trees a better chance to grow. Reasonably good forest conditions could, under proper regulations for cutting, be introduced and a continuous supply kept up. This statement as to the condition in the township of Burleigh may be taken as fairly typical of the course of natural forest regeneration in nearly all the fire-swept lands which came under the observance of the commissioners. Much of the forest lands now looked upon as of little use will yet, under proper protection, be very productive. The main feature of forest preservation must be protection from fire.

To the north of the height of land which sheds water into Hudson Bay, it was found that some timber lands had been burned over through the carelessness of Indians, but the Hudson Bay officials there had promised to help the Government in protecting the forests. The commissioners proceed to say that, though in earlier years the lumbermen confined their operations to taking out trees which measured at least 14 inches diameter at the butt, many rafts were observed to-day to consist of mere poles--six inches or so in diameter. This practice should be promptly stopped by the Government.

The commissioners give the following idea of the rate of growth of white pine: A young tree which would cut only one log 8 inches in diameter and 16 feet long, measuring 16 feet, board measure, would, if allowed to stand for thirty years, grow in diameter at the rate of one inch in five years - in some cases the growth is an inch in two years—and hence would give a butt of 14 inches diameter, 16 feet long, or 100 feet of lumber, board measure. In addition to this, however, this tree would have grown in height sufficiently to give two more logs, one, say of 11-inch, and one of 8-inch diameter, both 16 feet long, or a total of 164 feet, board measure, for the tree. Thus, a tree that required, perhaps, 40 years to make its first 16 feet of merchantable timber would in 30 years more have increased to 164 feet.

The commission suggests that a market should be secured for the "thinnings," which should be taken out where the timber stands too thick, and the idea is put forward that much of this apparently useless forest material might be utilized in the manufacture of pulp and small wood goods, or for the production of charcoal for smelting ores.

In conclusion, the commissioner recommends that—

1. The present system of fire ranging inaugurated by the Government in 1886 be extended so as to be compulsory on all the holders of timber berths; that all unlicensed timber land contiguous thereto be also protected by rangers employed by the Government, and that all fire rangers be subjected to the inspection and control of the Department of Crown Lands.

2. That the officials of the Hudson Bay Company be asked to co-operate with the Government in preparing and printing fire proclamations in the language of the Indians of the northern districts, to be posted along the canoe routes throughout the country.

3. That for all unworked limits on which the ground rent shall be two years in default on the termination of the present license year, the license shall not be renewed, but the berths be held by the Crown as forest reserves.

4. That license-holders be not allowed to cut any trees for logs smaller than will measure 12 inches across the stump, two feet from the ground, unless under special forest conditions, with the sanction and under the supervision of the district forest ranger.

5. That the Government take power by Order-in-Council to withdraw from sale a location, and set aside, to be left in permanent Crown forest reserves, such areas of territory as are generally unsuitable for settlement, and yet valuable for growing timber.

FIRES OF THE MONTH.

Jan. 12th—North-West Elevator Co.'s elevator, Cypress River, Man.; partly insured. — Jan. 13th—The Dominion Paper Box Co.'s building, Adelaide street, Toronto; loss, $50,000. ——Jan. 17th—A. Merizzi's woolen mill, Napierville, Que., loss, $10,000.——Jan. 21st—Richelieu and Ontario Co.'s office, Montreal; damages, $800.——Jan. 23rd—The power house and car house of the Metropolitan Street Railway Co., Toronto; damages, $10,000; fully insured.——Feb. 1st—The Doherty organ factory, Clinton, Ont.; damages, $75,000, insurance, $35,000.

—J. H. Still promises to have the St. Thomas electric street railway in operation before Dominion Day.

—The voting on a $25,000 system of waterworks for Mount Forest, Ont., took place January 20th, and resulted in the by-law being sustained by a majority of 49.

—The trustees of Havergal Ladies' College, Toronto, have taken out a permit for the erection of a three-story brick school building at 356 Jarvis street, to cost $35,000.

—Edward Hooper, Toronto, has taken out a permit for the erection of a five-story brick addition to the Grand Union Hotel at the corner of Front and Simcoe streets, Toronto, to cost $30,000.

—The Ontario Wind Engine and Pump Company has taken out a permit to erect a two-story brick machine shop and office at the south-west corner of Atlantic avenue and Liberty street, Toronto, to cost $3,000.

—It is stated upon good authority that the H., G. & B. electric railway will be run through to St. Catharines if the Decew Falls power scheme proves a success, so that the company can get power from that source.

—In view of the Canadian Pacific's decision to bring Toronto business round by Carleton Place a large number of new locomotives will be put into service on the line, orders for some forty new engines being now in the hands of locomotive builders.

—The Polson Iron Works Company, Toronto, has secured the contract from an English syndicate for the building of a steamer to be used on the Yukon River. She will be a stern-wheeler, dimensions 45 feet long and 9 feet beam, and will draw only 15 inches of water.

—The Ontario Government granted the sum of $35,000 towards the construction of an International railway bridge across the river St. Lawrence, at Cornwall, on the line of the Ottawa and New York Railway; provided that aid be granted also by the Government of Canada.

—A big scheme is on hand for the incorporation of the Montreal and Champlain Canal Co., which proposes to construct a canal from the St. Lawrence to the Richelieu River, a distance of 18 miles. The company is to have a capital of $6,000,000. Albert J. Corriveau is the promoter.

—There was a general strike of men employed by the Canadian Pacific Navigation steamers in British Columbia, February 2nd. They demanded an increase in wages in view of the rush to the Klondyke. Some of the strikers were placed under arrest charged with violating the laws governing the sailing of vessels. They appeared before the magistrate, who gave them the choice of going to work or jail. They chose the former.

—The annual report has been issued of the Niagara Falls Park & River Railway. The report shows the number of passengers carried is away ahead of previous years. In 1896 the passengers carried numbered 497,000; in 1897 the number carried was 579,000, giving to the year 1897 an increase of 82,363 passengers over 1896. The Niagara Falls Park & River Railway was established in 1893, and has been a success ever since its inception. W. Phillips, who has completed his first year as acting manager of the road, was appointed general manager at an increased salary.

—The second inter-provincial conference of Canadian mining engineers and mine managers will be held in Montreal, under the auspices of the Federated Canadian Mining Institute, commencing Tuesday, March 1, and continuing the three following days. Some forty papers will be read and discussed by the members of the association. The proceedings of the conference, which will take place in the ladies' ordinary and other rooms of the Windsor Hotel, will be open to the public. The annual banquet of the association will be held at the Windsor Hotel on the evening of Thursday, March 3rd.

—Although little or nothing has been said about it, the Chateauguay and Northern, or, as it is better known, the Bout de l'Ile Electric Railway Company, has done a very considerable amount of construction work during the season past. The system has been connected with the Canadian Pacific Railway freight yards, on Moreau street, Montreal, the meeting of the two roads being effected near the old North Shore freight office. This new branch, which brings the Chateauguay and Northern into immediate connection with the C.P.R., embraces about 1½ miles of track, the rails being 60 lbs. to the yard, and extending all the way from Lasalle street to the Canadian Pacific yards, just mentioned, so that goods can now be billed from any part of the C.P.R. to any point on the electric road in question.

THE KNAPP ROLLER BOAT.

Editor CANADIAN ENGINEER :

SIR,—Now that the Knapp boat is laid up for the winter without a speed trial, it may be of interest to consider some of the points which have been made against her success. Foremost among these is the great wind question. It is claimed that wind pressure reduces the speed of the " Campania " from 560 to 180 knots a day. Is this the whole truth? I think not. A vessel of that class is submerged about 33 feet, or nearly two-thirds of her entire bulk. The air, through which the smaller portion of the vessel has to make its way, is some 700 times lighter than the water which resists the submerged portion. But the water in a high head or quarter wind acquires under the influence of the wind, a very rapid motion. This rapidly-moving water, weighing hundreds of tons, is hurled against the bows of the on-coming vessel. A vastly lighter body of air is at the same time opposing her upper works. But which has the greater effect in reducing her speed? Obviously 700 tons of water will retard her speed more than one ton of air. It is probable, may we not say certain, then, that the " Campania's" speed is reduced, not by the wind pressure on her upper works, but by the resistance of the rapidly-moving water against the submerged portion of her hull. The wind pressure in itself can add but very little to the retardation.

Now, discarding all other elements but those of water resistance, how will this affect the full-sized Knapp boat? To begin with, the immersion will be considerably less than one-half that of the "Campania." The serious resistance will therefore be diminished in that proportion. But this is not all advantage to the Knapp boat. The trials have shown that increase of water resistance produces increase of speed, thus completely reversing present conditions. The weight of water flung against the submerged portion, which is curving downwards and away from the on-coming wave, will tend to "sweep her legs from under her," just as a beam sea causes the staunchest boat to roll. But to roll is just what Mr. Knapp's boat is built to do. Consequently this terrible foe of present-day craft will be an actual friend to the new monster.

But how about the wind on the upper works? Here, indeed, there is a tremendous increase of surface to play upon. But here also another principle appears which may very possibly surprise the cock-sure prophets. If two moving bodies meet, the lighter of the two will be inevitably overcome by the heavier. Now the Knapp boat will weigh some 15,000 tons, and will present 112,500 square feet to the wind, less the submerged portion. Now in calm weather, at a speed of a mile a minute, the heaviest pressure of wind would be about 18 lbs. to the square foot, or, adding the resistance of a 40-mile gale, about 26 lbs. to the square foot. The weight of wind to be encountered would thus be about 1,012 tons in calm weather, or 1,462 tons in a 40-mile gale. What will happen to that 1,462 tons when 15,000 tons are thrown forcibly against it at the rate of a mile a minute? Which must give way? I imagine there can be no two answers to this problem.

But very competent engineers think that the surface presented to the wind would be more accurately represented by multiplying the length by one-half the diameter, for the reason that the shape of the boat and its peculiar motion would greatly reduce the retarding effect of the wind upon it. If this be admitted, the pressures given above must be divided by two, giving 506 tons wind resistance in calm weather, or 731 tons in a 40-mile gale, and with the boat going at a mile a minute. It will be seen, therefore, that everything against the boat is conceded in the above argument, while in what I am about to say I shall concede everything in favor of my examples.

It will doubtless be objected that the horse-power necessary to drive that 15,000 tons against 1,462 tons at the rate of 5,280 feet a minute will be so enormous that the boat could never carry it. To this the inventor replies that the momentum of his boat will be in itself sufficient to overcome wind resistance, and all his engines need do is to roll his boat *in* the water at that speed. The weight of the boat and the aid of the resisting water will do the rest. But we are told "there is nothing in momentum." Fortunately that fact can be tested, because ships are not the only moving bodies which are confronted with wind resistance. Let us take then as a test the Holman engine, which recently ran at the rate of a mile in 28 seconds for a short distance, and made the whole mile in 32 seconds, or the Empire State express, which has a record of 34 seconds for a mile. It is noticeable in both cases that a long run was made first, in order to "get up speed;" in other words, to acquire momentum. The Empire State express traveled 17 miles for this purpose; the Holman engine, 3 miles. Both present approximately 120 square feet of area when driving directly against the wind. If the wind is slightly on the quarter, this area would be much increased. But let us take the smallest area for our purpose. Taking the speed at two miles an hour the wind pressure would be 4 1-3 tons upon the square surface area of the train, head on. Reduced to horse-power, this would be roughly 3,000 h.p. But the engine actually possesses only about 1,500 h.p., and this is mainly used in overcoming the mechanical resistance of the inertia of the train, and all the friction of the machinery. Here, then, is a problem for objectors. It is evident that power is required merely to move the train. It is also evident that the engine does not possess sufficient horse-power to overcome the wind resistance alone, as ordinarily calculated. Whence then does the power come that not only moves the train, but overcomes the wind pressure also, and speeds along at a rate of a little under or over two miles a minute? Mr. Knapp says it is gained from the momentum. The engineers say there is nothing in momentum, but they do not answer this curious problem. Until they can it is at least possible, perhaps even probable, that Mr. Knapp is right. What you say in your July number as to the limitation of the effective power of the engines is admitted by Mr. Knapp to be true, and he has all along objected that this was a wasteful mode of applying the power. He wishes to apply it direct to the axle by the action of cranks.

I may add that I know the inventor well, and have constantly discussed the boat with him for the last three years. I do not wish him to be held responsible, however, for anything I have said except when it is directly attributed to him.

ONE OF THOSE INTERESTED.

Kingston, Dec., 1897.

NOTE.—The writer of the above letter has, in starting out, evidently confused wave motion with current. If he goes out on Lake Ontario after a storm, when a dead swell is on, and drops a stick on the water, he will find that though the waves heave ever so high the stick does not move away, but swings back and forward with each undulation. Even in a gale the surface water blown along by the wind is only a shallow "skim," and never keeps pace with the undulations of the waves. All the arguments built on this misconception fall to the ground, and need not be discussed. The writer asks, "What will become of that 1,462 tons (wind pressure) when 15,000 tons (weight of boat) are thrown against it?" One might answer that question by asking what will become of the roller boat when, with motive power limited to the slight leverage obtained by the weight of the internal machinery, it is exposed with its 112,500 square feet of surface to a howling gale? Our correspondent talks of the momentum of his boat overcoming the wind resistance, but how will he get his momentum without power? And power he has not got, and cannot get a boat on this plan. He is equally wrong in his speculations on the speed of a railway train. It is power, and not momentum, that enables a train to get into motion on an up-grade against a gale of wind. A gentleman of wide experience and good judgment, both on marine and mechanical questions, and who has studied Mr. Knapp's boat, is of opinion that three to six miles per hour is all she is capable of even in a comparative calm. With regard to the arguments used by "One of those Interested," he says:

" The supposition that the movement of the water against the direction of the vessel would help it to go ahead is absurd. The current of a river would be analogous to such a movement of water (if it existed). Therefore, if the Knapp boat was rolling up a river, the more rapid the river the faster the boat would run up it! The certainty is that the same law would hold good as in the case of any vessel. The speed up the river along the land would be the ordinary speed of the boat in calm water, minus the miles per hour of the current against it. The illustration is given of a beam sea causing a boat to roll. But a beam sea rolls the boat away from the wave, not towards it. With reference to the action of wind on the upper works, the proposition is made that if two moving

bodies meet, the lighter will be overcome by the heavier. Quite so, but the speed of the heavier will be diminished in proportion to the weight of the lighter. Therefore, the heavier the wind the slower the boat working against it, and, of course, the larger the surface acted upon the greater the retardation. The error here is on assuming that the weight of the boat (15,000 tons) is any factor. It is not the weight of the boat versus the wind, but the power of the engines, whatever that may be, versus the power of the wind, with the uneven surface to act upon. But the success of the new departure must be judged by results. Taking the power put into the boat, the manner of its application, and the resistance of the peculiar form of the hull into consideration, it was estimated by experts and practical men that the speed in still water would be about four miles per hour. This at the experimental trials proved to be the limit, thus demonstrating the accuracy of the calculations. The same power on a similar displacement with a scientifically-shaped hull would have developed about 15 miles at least. But supposing a reasonable amount of speed had been obtained, what then? The monstrosity is incapable of fulfilling any one of the ordinary requirements of navigation. There can be no accommodation for passengers. It would be impossible to carry cargo in such a shape that it would not be ground to powder as it was rolled around. The vessel could not be brought to an anchor, if it became necessary. In fact a more utterly unpractical form of ship could not be devised, even if the inventor had had that in view as the sole object of his labors.

A contingency that the inventor cannot have considered as he talks of a mile a minute, and that is that at this speed, allowing 20 per cent. slip, the 20-foot hull would have to revolve 100 revolutions per minute, at which speed the centrifugal force would send the cargo through the ship's bottom, and if not accurately balanced, would shake the vessel to pieces.

In an interview with one of the Toronto papers, Mr. Knapp said he would not attempt to steam against a gale, but as winds move in cyclones where diameter is never more than 400 miles, he would just roll out of the boundary of one of these cyclones, and then go on. R. F. Stupart, Director of the Meteorological Service, has some knowledge of the character and extent of cyclonic movements of wind, and in reply to an enquiry on this matter, Mr. Stupart says: "It sometimes happens that severe tropical cyclones are not more than 400 miles in diameter, and sometimes considerably less; it is seldom, however, that the storms occurring on the trans-Atlantic and Pacific routes are less than 1,000 miles in diameter, and frequently they are much more. A southerly gale in advance of a storm centre will oftentimes begin to blow near the coast of Ireland, while in the rear of the same storm centre a north-westerly gale is still blowing off the coast of Newfoundland. As these storms do not progress eastward at a greater average rate than 30 miles per hour, it will doubtless be possible for the roller boat when it acquires a speed of *sixty miles per hour*, to keep out of the bad weather."

ELEVATORS, HYDRAULIC V. ELECTRIC.

Editor CANADIAN ENGINEER :

In your January issue, P. W. Moses, consulting electrical engineer, of New York, takes exception to some of the statements in the article on elevators in the December issue. I can not see where Mr. Moses proves my statements to be incorrect, and therefore it is difficult to answer him. Also he is an expert, and the article was written for an engineer like myself, and I feel flattered that it was of such moment that it was taken up by a New York electrical engineer, but as Mr. Moses has given his opinion, I will try to follow him, and simply repeat what I stated before, and what are practical facts.

In the first place, I do know more about hydraulic than electrical elevators. I am as well acquainted with electrical elevators as I care to be, and I very likely know a great deal more about the generating end of the electrical plant than Mr. Moses does; not theoretically, but practically. It is easy to figure on any subject, but figures are not what we pay for: it is coal, oil, and repairs, with labor, interest, etc. Mr. Moses says that an engine and generator can be put in for $5,000. It can, but it is not enough, and will not purchase a plant large enough for five elevators, let alone a duplicate plant, whereas a first-class compound pumping engine can be put in in duplicate large enough for five elevators for the sum of $5,000, and if the architect put in an electric generating plant in keeping with the rest of the building, it would not be a one-horse show that could be purchased for $5,000. I know what it costs to install generating apparatus, also hydraulic elevators, and if the proper specifications were got out, and the manufacturers thought that they would get a fair show, the five elevators could be installed in a first-class manner with pumping machinery, for $30,000. The elevators, if electric, cannot run off the lighting engines satisfactorily; no matter what Mr. Moses thinks, it is very seldom done, except in very large stations or where they have only one elevator.

In the matter of safety, Mr. Moses proves just what I stated, namely, that the electric is more complicated, which does not tend to safety, but is dangerous, for the electric devices that you are depending on often fail to work when you want them, because the current is off. He says that there is not an elaborate cycle of changes during the time of starting, and then goes on to describe the very changes I spoke of. The electric man says that all you have to do is to push the button in the car and it starts, but just trace out all that occurs from the time the button was pushed until the car was at full speed. Then watch the hydraulic apparatus. You move the hand-wheel and it moves the valve direct. Nothing could be simpler, but the electric is simple enough to anyone looking through electric spectacles. Mr. Moses says that the electric elevator does not appear complicated. It does not appear so, but it is very complicated. Just the same in comparison with hydraulic. Even when he compares the electric elevator with the hod-hoist, which, by the way, I think is an apt comparison. He states that they are in use in hundreds of New York buildings, and receive the least possible care and attention. That may be one of the reasons that they run so badly: or they may get the least possible care, and yet, that least possible may mean a great deal of work. A gentleman went to New York to look into elevators before installing a large plant, and everywhere that they had hydraulic the practical men around the plant spoke well of them, and where they had been electric, almost invariably they were dissatisfied, and said, "put in hydraulic by all means."

Mr. Moses also says that the comparative wear and tear is yet to be determined. It may be by Mr. Moses, but I can cite cases in Montreal, Buffalo, and Toronto, where electric elevators cost more for worn out parts in the first six months than any hydraulic would in two years, and he acknowledges that the life is shorter for the generating apparatus, and as that generating apparatus costs more than three times what the same size pumping plant would cost, it does matter a great deal. I will not go into figures, as I can prove by figures that the electric is the more economic as far as coal is concerned, but I also know that it costs more for repairs on certain electric elevators than it costs for current, and when material and labor are taken into account, the economy is on the side of the hydraulic.

I again make the statement that the plant should be the full capacity of the five elevators, and my practical experience as engineer of the Incandescent Light Company proves that, and anything short would be folly. My experience there proved to me also that nearly all the complaints from customers were due to elevators coming on when the load was light, and the company has since put them all on a separate circuit, thereby improving the lighting system wonderfully. When the load is heavy, the elevator adds such a small percentage that the effect is not noticed That is why the New York companies can run the electric elevator with practically no effect, as their load is heavy all the time.

In conclusion, I know more about the condition of Toronto and its City Hall than Mr. Moses does, and I could prove even to Mr. Moses that hydraulic elevators is what the City Hall should have, if he were anything but an electrical engineer. One of the proofs in the previous article was, that all the manufacturers making both kinds of elevators says they should be hydraulic, and only one, who makes only electric elevators, says they should be electric, and of necessity electrical engineers would say the same. Mr. Moses knows more about electricity than I do, no doubt, but he very likely has not the knowledge that the practical side of the question gives by long experience.

Toronto, Jan. 25th, 1898. ED. PHILIP.

For Sale Cheap

A New 100 Kilowatt 125 Volt Multipolar, Direct Current Dynamo

Latest steel frame type, with iron clad armature.

A most complete set of Station Attachments. Suitable for Incandescent Lighting, with a capacity of 2,000 16-candle power lamps, or for power or electro-chemical purposes; has never been used only for a test.

For particulars apply to E. H. HILBORN, 74 Brunswick Avenue, Toronto, or to JOHN TOLMIE, Kincardine.

CHAP. V.

ROADBED CONSTRUCTION.

ARTICLE 27.—FOUNDATIONS.

The foundation of a structure is much more important than any other feature of its design, as on its security depends that of the structure itself. We may therefore be justified in examining closely into the bearing power of soils, the various methods of increasing it or distributing the load over greater areas, and the various methods of sinking or making foundations.

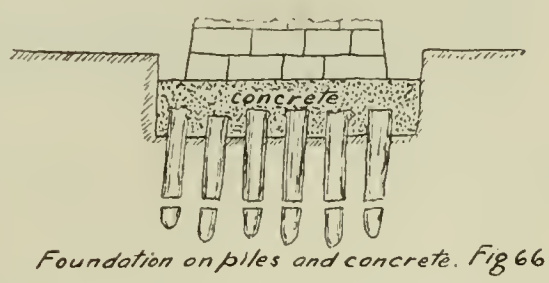
The bearing power of soils varies very much, being least for soft clays and unconfined quicksands, and increasing through sand, gravel, firm clay and hardpan to solid rock; it may be as low as one-half ton per square foot, and as high as 180 tons per square foot, but it is only with the lower values that we need deal. A good clay foundation will bear safely 2½ to 4 tons per square foot, and dry sand or gravel from 5 to 6 tons, while cases have been known of 10 to 11 tons per square foot being carried. In railway work 3 or 4 tons per square foot is usually all that we want to put on to a foundation; consequently, whenever good firm clay (which will not be watersoaked), sand or gravel are reached, the foundation may be considered safe, provided we have sounded several feet, and in case of important structures, many feet below the foundation bed, to see that the substrata are equally firm. Rankine's earthwork formula takes account of the depth of the foundation beneath the ground level, and one rule in use in the Western States is that the safe load per square foot on sand is 2 tons + 1 ton for each 10 feet in depth. No account has been taken of the friction of the soil on the sides of the structure below ground level. This is only of importance where the foundations are sunk by pneumatic caisson or open dredging, in which case it is variously estimated at from 200 to 600 pounds per square foot of surface exposed to side friction. If the caisson is of cast iron, about 300 lbs. for wrought iron, 900 lbs. for masonry, 300 to 600 lbs. for timber, and for piles 500 to 1,000 lbs. per square foot.

*This series of papers will be Issued in book form as soon as they have appeared in THE CANADIAN ENGINEER.

FOUNDATIONS ON LAND.

Where a firm foundation is obtainable within a few feet of the surface, all that is necessary is to dig a pit below frost level, or to any required depth and commence stonework at once, or often lay 1 or 2 feet of concrete to get a uniform bed to lay on, if the foundation is bouldery or uneven; but if, on the other hand, the foundation bed shows soft spots or uneven bearing power, the difficulty may be overcome by using a deep bed of concrete which will span over small spots (provided there is no danger of undermining by scour from an adjacent river, liable to change its channel), or by using a grillage of timber instead, in cases where the timber will always remain watersoaked, but not otherwise. Again, the same expedients may answer if the whole foundation is somewhat, but not very, soft, by spreading out over a larger area. When, however, it is found that the foundation is too soft for such methods even if thoroughly drained, and that it will not pay to dig down far enough to reach a firm one, recourse must be had to some artificial method of obtaining greater bearing power, the usual way being to drive piles, although in some cases where cost is no object or the piles would be subject to decay, large platforms formed of cross-layers of steel I beams or rails bedded in concrete (as in Chicago), have been used to great advantage, the transverse strength being such as to enable a very much enlarged area being used. When sufficient piles are driven to carry the load required they may be cut off level and capped by drift-bolting on a double layer of 12 inch by 12-inch timbers, as a base for stonework, or preferably either on the broomed heads of the piles or after sawing them off, a layer of concrete is placed and also rammed around and between the piles, in which case the earth between the piles will take a portion of the load, being much compacted by the driving, indeed, in cases where timber is scarce, a method has been adopted of pulling out piles after driving and immediately filling the holes with well rammed sand, the compacted earth and the sand pillars together carrying the load safely. Cast iron and

wrought iron screw piles are used extensively in ocean jetty, lighthouse, and pier construction, but for foundations to masonry structures on land the wooden pile is in



Foundation on piles and concrete. Fig 66

almost exclusive use; of the various ways of driving piles by steam hammer, drop hammer, water jet, gunpowder explosions or insistent weight, the first three are the only ones worth considering.

The water jet is used economically where water is plentiful, ordinary pile driving inconvenient, and in sandy, quicksandy or silty soils (indeed it is often the only means of driving piles in bad quicksands), the water is carried in a pipe down the side of the pile and is projected in large quantities and considerable pressure just below the point of the pile; this allows the pile, assisted by a dead weight or by light blows from a small hammer, to sink very rapidly, the water rising in a film around the surface of the pile and almost eliminating friction as long as the action continues, but after driving is finished the sand or earth settles around the pile and gives as high a bearing power as with hammer-driven piles.*

The Steam Hammer weighs from 4,000 to 5,000 lbs. and sits on the head of the pile, striking a blow with a piston loaded with about 3,000 lbs., the stroke is $2\frac{1}{2}$ to 3 feet in length and about once per second. This keeps the soil and pile in a continual vibration and effects more than the occasional, though more severe blow of a drop hammer. Although a steam hammer is unable to drive in very hard ground economically, and is not economical where only a few piles are to be driven in a place, as the cost of transportation of hammer, boiler, steam-pipes, etc. is too great, yet wherever a great many piles are to be driven in one locality, as on docks, large foundations, etc., or where the outfit can be economically transported from place to place, it can drive piles much more cheaply and quickly than a drop hammer.

The Drop Hammer is raised either by hand, horse, or steam power, and usually a trip is arranged to free the hammer automatically at the top, the line being brought down again by hand, which takes time. In order to avoid this, sometimes, in driving by steam, the line is permanently attached, and a friction drum is utilized to let it drop without tripping, thereby dragging the line with it and lessening the force of the blow, but economizing time. The chief danger in this method lies in its abuse by dishonest contractors, where the pile-driving is specified for certain maximum penetration at the last blow, in which case, a slight friction on the drum will materially lessen the effect of the blow. The weight of drop hammers varies from 1,200 to 2,000 lbs., and the drop from 15 to 30 feet depending on the hardness of driving and pile head, and length of leads. The drop and steam hammer are in general use, and the load which a pile can safely carry may be approximately estimated by various empyrical formulæ, when the drop, weight of hammer, and penetration at the last blow (with an unbroomed head to the pile) are known, such formulæ are usually on the safe side, because although at least one instance has been given of a pile refusing to drive at all, and yet after a day's rest going five or six inches, yet the usual experience is that piles which will penetrate several inches at a blow, after long continued driving, will penetrate less, or almost refuse to drive after a rest of a day or two allowing the material to settle around the pile.

*See *Engineering News*, Vol. 31, 1894, page 316, for jet pile driver.

The three formulæ looked upon most favorably in America are:—

(*a*) Weisbach's or Sanders—

$$\text{Safe load} = L = f \times \frac{12\,WH}{S} \quad (f = \tfrac{1}{3} \text{ to } \tfrac{1}{8}).$$

(*b*) Trautwine's—

$$\text{Safe load} = L = f \times \frac{46\,W\sqrt[3]{H}}{S+1} \quad (f = \tfrac{1}{3} \text{ to } \tfrac{1}{12}).$$

(*c*) Wellington's—

$$\text{Safe load} = L = \frac{2\,WH}{S+1} \text{ (drop hammer).}$$

$$\text{Safe load} = L = \frac{2\,WH}{S+\frac{1}{10}} \text{ (steam hammer).}$$

(L = safe load in lbs.; W = weight of hammer in lbs.; H = drop of hammer in feet; f = factor of safety; S = penetration, per blow, in inches, for average of last four or five blows.)

Where penetrations are as much as two inches or over there is not much to choose between all these formulæ; but for small penetrations the 1st one is evidently inapplicable, giving abnormally high results; on the other hand, the third formula is conservative under all conditions, simple in use, and admits of a modification for steam hammer driving, in which *stiction** is not an element to be considered. It is also applicable down to zero penetrations for ordinary weight of hammer, drop and length of pile, as $L = 2\,WH$ is about what a pillar 12 or 15 inches in diameter and, say, 20 feet long will safely stand (taking $W = 2{,}000$, $H = 25$).

These formulæ neglect many small losses of energy in driving, and are, therefore, only empyrical; but the results accord fairly well with the few facts known regarding the safe loads on piles. Evidently in ordinary soils, the skin friction is the important element in their sustaining power, as the load carried on the point of even a blunt ended pile would not be very great unless on solid rock.

Of the ordinary losses of energy in pile-driving, the only important one (neglecting the friction of the leads, the compressing of the pile, the bouncing of the hammer, which latter can be remedied by lessening the drop, or getting a heavier hammer), is the brooming of the head and point under hard driving. To prevent the former, a heavy iron band about three inches by one inch should be fitted around the head, and when brooming does occur, it should be sawed off at once. While in hard or bouldery ground the point should be shod with straps of iron and made rather blunt—in fact some drive with piles almost without a point, claiming that brooming is thus prevented—in quicksand, a pile turned butt downward will often be the only means of keeping it down during driving, and in all cases where piles are subject to severe vibration they will take a much less load than where it is a quiescent one. This is not included in the formulæ and must be provided for in the design.

For permanent piling in fresh water districts such woods as cedar, oak, yellow pine, rock elm, spruce and tamarac are in common use, being given somewhat in order of merit for durability, while any good wood may be used for temporary work. The cost for ordinary lengths will vary from five cents to eight cents per foot in favorable localities, to twelve cents or fifteen cents for oak piles at a greater distance, and even twenty-five cents or

* Stiction is that excess of frictional resistance offered, when a body is started from rest, over the continuous frictional resistance offered to a body while in motion, under the same conditions of surrounding material. C. B. S.

thirty cents per foot for the same in great lengths of fifty or sixty feet; driving will vary from two cents or three cents per foot in situations where great quantities are driven by steam hammer, to four cents or five cents per foot where driven by a track pile driver on cars; but for ordinary railway construction work, scattered and in small quantities, eight cents to twelve cents per foot is not out of the way. An ordinary price on railway construction is about thirty cents per foot for good piles, 12 inches in diameter at the small end, in place in the work, and fifteen cents per foot for all cut-off ends, this includes all labor of driving and cutting off to the exact height if on land, but cutting off under water is extra, and sometimes a matter of considerable expense.

Deep Foundations on Land. — Where foundations require to be carried down for any considerable depth, it is more economical to timber and sink vertically than to put earth slopes on the foundation pit, such timber will, in general, consist of vertical hand-driven sheet piles and horizontal rings of timbers and braces to sustain them at five or six foot intervals, as shown Fig. 67, Plate XIX.,

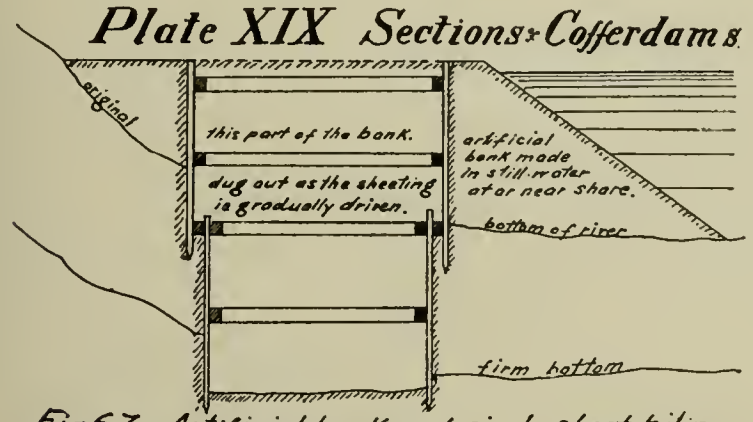


Fig 67. Artificial bank and single sheet piling.

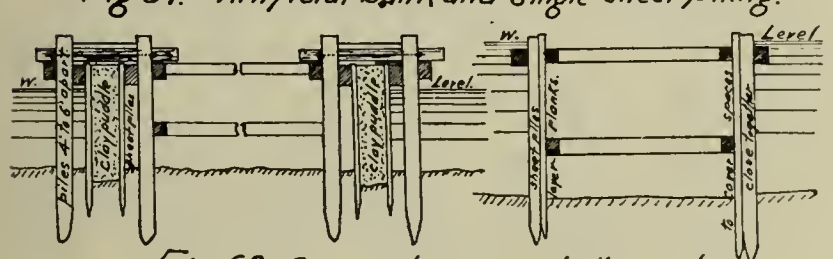

Fig. 68 Coffer-dams for shallow water.

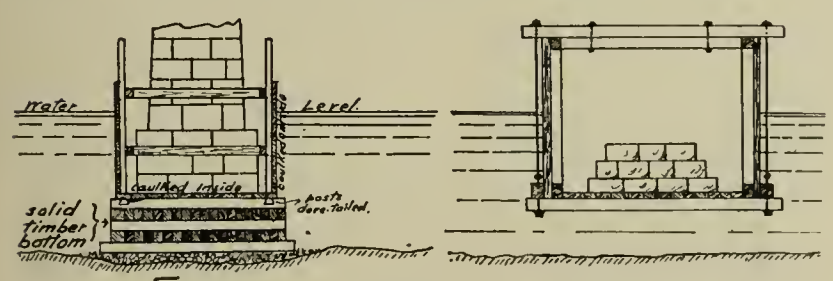

Fig 69. Floating Cofferdams on good bottoms.

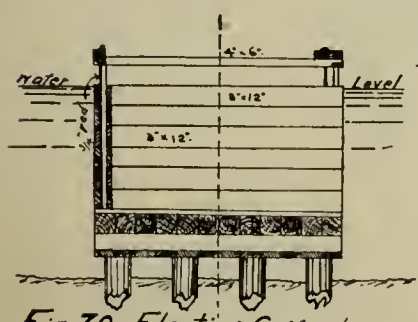

Fig. 70 Floating Cofferdam on piles

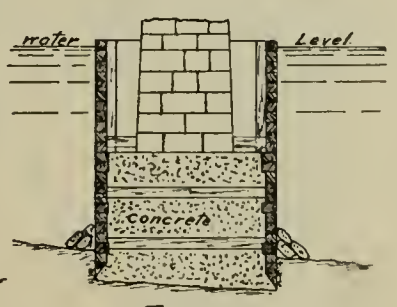

Fig. 71. Concrete-filled bottomless Caisson.

and in planning such work it is well to remember: (1) To allow for extra room more than is apparently required, in order to give freedom of movement, extra timbers, etc.; (2) To be sure to find out how deep it is to good bottom before digging is begun, in order to see whether piling might not be less expensive, and chiefly so as to be able to say definitely how many rings of timber there will be, and how much extra room will, therefore, be needed to step in all around about 15 inches every 10 or 12 feet in depth; this is a very important consideration. See Fig 67.

FOUNDATIONS IN WATER.

When masonry work is to be built in water, the considerations which determine the method to be adopted are: (1) The depth of water and its fluctuation in level. (2) The depth of soft material underlying the water which must be penetrated to secure good foundation. (3) The velocity of the current. (4) The money and materials available.

Of these considerations Nos. 1 and 2 are most important, and the total depth from water surface to bottom of structure will determine whether the foundation should be obtained by:

(*A*) Fixed cofferdams; (*B*), floating cofferdams, with solid timber bottoms; (*C*), bottomless cofferdams or caissons; (*D*), compressed air; (*E*), open dredging.

Fixed Cofferdams.—These are used where there is shallow water, at most only a moderate current, and where the bottom is of such a nature as to admit of sheet piles being driven in and the foundation suitably excavated to a firm foundation bed. This may be accomplished in various ways. Where the structure is near shore and waste excavation is available, it will pay to make an embankment above water level, and carry down hand-driven sheet piles kept in position by rings of timber, the excavation being always kept about level with the bottom of the sheet piles. This method is illustrated in Fig. 67. If, however, the structure is not thus situated, the sheet piles are either driven in a double layer, as in Fig. 68, or a single row of Wakefield sheet piling is used (this is an artificially made sheet pile composed of three planks spiked together to form a tongue and groove). If any of these methods are employed, a centrifugal pump will be kept busy keeping down the water while the foundation courses are being laid, but in case such pumping power is not advisable or available a more expensive form of cofferdam can be used, as in Fig. 68. Rows of guide piles are driven at considerable distances apart, then walings are bolted on, and a double row of sheet piles is driven around the area to be unwatered, between which is rammed clay puddle, making a very watertight, but expensive, cofferdam. This is generally employed in extensive works where the area is to be unwatered for some length of time.

Floating Cofferdams with Solid Timber Bottoms — It is moderately certain that as long as timber is covered with running fresh water it will never decay, and it is even contended that in any fresh water it is practically safe also; this has led to the adoption of methods of foundation building which do not involve the unwatering of the bottom. If the bottom is bare and moderately level, or can be dredged to a good bottom and levelled up with broken stone, it is manifestly easy to build a watertight box with either a solid timber (Fig. 69) or stone-filled crib, or only a plank layer, as a bottom (Fig. 69), and, after floating it into position, sink it, by building in it or by external loading, and after the structure has been built up above water level tear off the sides of the watertight box, leaving the bottom as a permanent part of the structure. If, on the other hand, the foundation is soft and good bottom can be reached by piling, the piles are driven to a firm bearing, sawed off under water close to the bed of the river, and the same operation as just described is gone through, the structure being landed on top of the piles as a foundation, as in Fig. 70. These methods are cheap and satisfactory in situations where the current is not excessive, but in very swift currents such constructions are not as manageable as the bottomless cofferdams to be described, and even where used, it is

found advisable to build the timber work and footing courses of masonry considerably (1 to 2 feet) larger than the neat work, which is laid out after the crib is in its final position. This provides for some permissible inaccuracy in sinking. The cribs are well drift-bolted together and the boxes caulked with oakum and dove-tailed or bolted down to the bottom, so as to prevent them lifting when the sinking process is going on.

Bottomless Caissons or Cofferdams.—Where no timber is desired under the masonry, or where the current is very swift, the method shown in Fig. 71 has been found best, but is only admissible where good foundations are easily obtainable. The bottomless box is floated into place, loaded until it sinks to the bottom, and then is either unwatered by having a large canvas flap around the outside of the bottom, held down by bags of concrete, thus nearly sealing the bottom, the caisson being then pumped out and the bottom excavated or levelled off with concrete, or else, if the bottom is already firm, as is usually the case in swift currents, there is no necessity for unwatering until a great depth of concrete has been put in, forming a watertight bottom; in the latter case, if there is an irregular rock bottom, the caisson cannot be made to fit it, and in order to keep the undertow from carrying away the concrete as fast as deposited, or even dissolving out the cement, it is found necessary to fasten a canvas flap around the inside of the bottom and load it down with bags of concrete, pea straw, etc., until a bottom has been formed And in depositing the concrete it is done by lowering an iron box, with a hinged bottom, containing about one cubic yard down to the bottom; the box is tripped, allowing the concrete to slide gently out, whereas it would become dissolved if allowed to fall any distance through water. After such a bed of concrete has been formed as is considered sufficient, the caisson may be pumped out and construction continued in open air.

Compressed Air.—Where a great depth of water and soft foundations are encountered the methods previously described must be abandoned. Early in this century the vacuum air process was tried, by which the excess of outside pressure forced soft materials up inside a vacuum chamber, this material being excavated, air was again extracted, and each time the hollow chamber of wood or iron sank down by its own or added weight; but this method was found uncertain in its means of directing the sinking, was capable of only limited application and failed entirely on encountering stiff clay or boulders, besides it did not enable the bottom to be personally examined and properly prepared for the foundation layers.

Very soon the plenum or compressed air process was tried, and to-day it is recognized as being in every way most satisfactory until greater depths than about 100 feet below water level are to be obtained, when open dredging through wells must be resorted to. Figs. 72, 73 and 74 show common forms of the same process. The drawings are almost self-explanatory, the pressure of air in the working chamber is constantly maintained, and the extent of the pressure must always be sufficient to keep out water; the tendency being for compressed air to be continually escaping around the working edges, and bubbling up to the surface outside the chamber. Where pneumatic cylinders are used, they are in pairs, sometimes braced together, the two supporting one end of a truss, and being completely filled with concrete after bottom is reached. See Plate XVI. One larger cylinder, as in the Hawkesbury bridge, with elliptical ends will, however, be much more stable.

Where large timber working chambers are used they must be very strong, as the whole weight of the pier will be carried on their backs until the working chamber is filled in, which is not until firm bottom is reached. It may be shod with iron or merely with timber, depending on the materials to be met with, and on top of this chamber may first be constructed a timber crib as in Fig. 74, extending up to the ground surface and filled with alternate pockets of concrete or broken stone sufficient to sink the chamber, which crib is built up gradually as the process goes on. Or, if advisable, the masonry may be commenced immediately on top of the working chamber as in Fig. 73, this will usually be done where the foundation is not a very deep one. The support which a deep caisson sunk by this method, or by open dredging gives to a pier and bridge, is partly by the bearing on the bottom and partly by friction on the sides, which is estimated at from 300 to 600 lbs. per square foot of surface, and is an enormous item in such a structure as that of Fig. 74, amounting to 2,000 or 3,000 tons. Of course, this resistance is not all to be overcome while sinking, for the continual movement and escape of a film of compressed air tends to aid sinking by lessening friction.

The material to be excavated is forced out of the discharge pipes by the compressed air, if it is finely divisible, by opening valves at the mouths of flexible pipes, but boulders, gravel, logs, etc., must be laboriously taken out of the air lock in small quantities, making the operation costly. The air shaft and lock form the means of ingress and egress, and it is a question whether it is safer and more convenient to have the air lock near the top or bottom of the shaft, the former, however, being safer for the men. The process of working the lock is to open one door, pass in, close the door, open a valve so as to raise or lower the pressure as the case may be, and then open the other door and pass on, some time being necessary to prevent injury to the lungs and ear drums; men can work in about

Plate XX

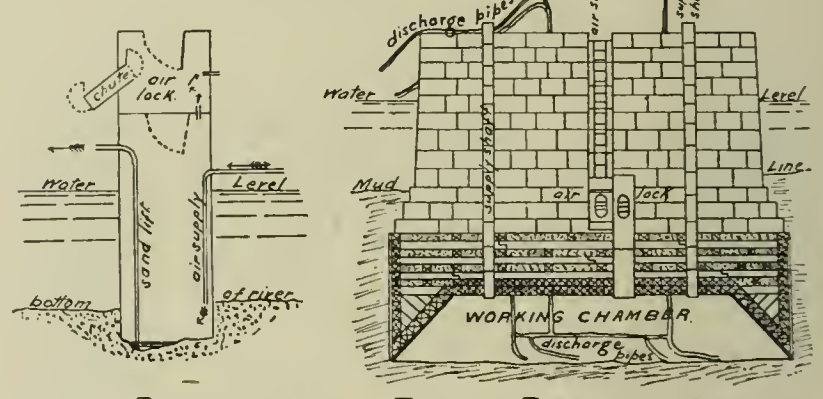

Fig. 72 Pneumatic Pile. Fig. 73 Pneumatic Caisson.

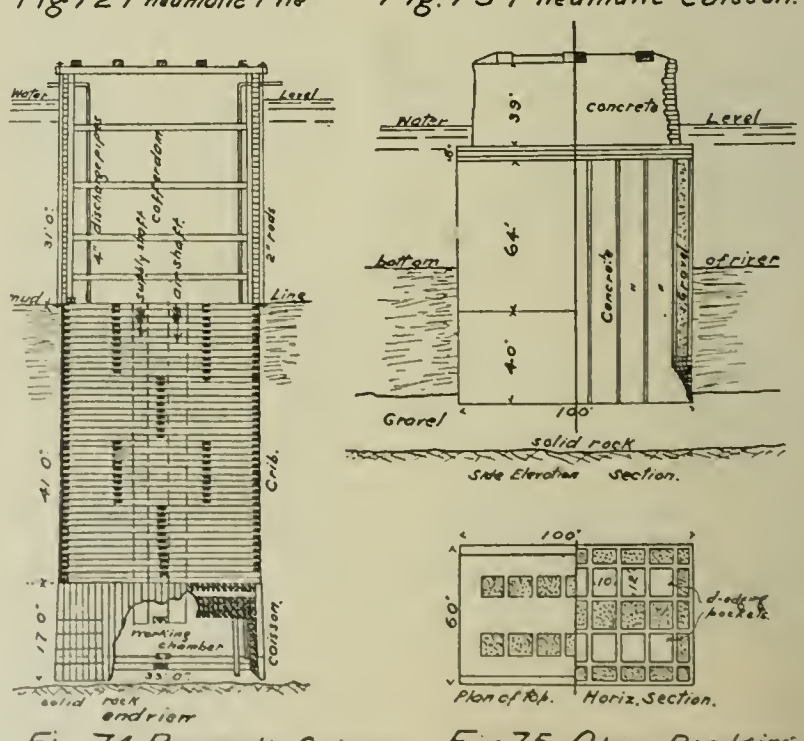

Fig. 74 Pneumatic Caisson with Crib and Cofferdam. Fig. 75 Open Dredging Caisson for Pier.

4 atmospheres pressure as a safe maximum, and then only for three or four hours for healthy men; with less pressure the period of labor may be lengthened, but on coming out to the open air the depressing effect of a lowered pressure must be counteracted by a strong stimulant like coffee, to prevent injurious consequences; and for reasons of safety the compressed air is taken from a receiver and not direct from the compressor. So that an accident to the machinery might not have an immediately disastrous effect by permitting an inrush of water before the men could escape.

The supply shafts marked are only used at the last, where concrete is passed in through them, to fill up the working chamber. The shafts themselves are also all filled with concrete, and the whole structure is a solid mass of timber, concrete and stone. Sinking foundations by compressed air has many advantages—the sinking can usually be quite accurately directed; it enables all the pier construction and excavation to proceed together; it enables all kinds of materials to be removed, and it permits of a careful examination and preparation of the bottom before concrete is put into place.

An example of such construction is detailed in Patton's "Foundations," at a cost of

$16.82 per cubic yard for the caisson material;
$10.76 " " crib "
$7.83 " " sinking "

making an average of about $20 per cubic yard. This was for a depth of 68 feet below water and in 56 feet of mud—evidently the cost would vary with the depth and the materials encountered, in this case the sinking was at the rate of 1½ to 2 vertical feet per day.

Open Dredging.—This method has been long practiced in India, where circular brick wells are built with heavy walls, and gradually lowered through soft soils by excavating and undermining, the material being raised in some primitive manner. This is improved upon now by using steel cylinders and excavating by clam-shell or other dredges. There is usually difficulty in controlling the direction of movement, and large logs and boulders are troublesome. So that open dredging is usually used only where the depth is too great to admit of using compressed air and where the materials can be freely dredged (in India, submarine blasting of boulders, etc., tended to crack the cast iron cylinders, but would, probably, not have a bad effect on timber cribs). A striking example of this process is that of the foundations for the Poughkeepsie bridge, which were sunk through a depth of 50 to 60 feet of water and 75 to 80 feet of mud, clay, sand and gravel, or a total distance of 140 feet below high water. (See Fig. 75.) The cribs, 100 feet by 60 feet, had 31 gravel pockets, extending from top to bottom, which afforded enough load to sink the cribs when undermined; there were 14 dredging wells extending from top to bottom 10 feet by 12 feet, in cross section, through which the dredging was done by a clam-shell dredge. The walls were 2 feet thick of solid timbers, laid in alternate lapping courses, well drift-bolted together, and after the cribs arrived at good bottom the wells and pockets were filled with concrete, and a floating caisson similar to Fig. 69 was brought out into position and built into until it sank on to the top of the crib. The chief difficulties in carrying out this process, aside from anchoring such a huge mass of timber in a swift current, preparatory to dredging, are that it is difficult to guide the crib in direction as it settles down, and that logs, boulders, etc., under the cutting edges, cause delay and necessitate, often, sending down divers. A combination of compressed air and open dredging has been used in Europe, in which several working chambers surround an open well, the men force the material out under the inner edges of the working chambers from which it is removed by a clam-shell dredge; the process is cheaper in handling the material, but uses an enormous quantity of compressed air.

(To be continued.)

For THE CANADIAN ENGINEER.

DISPOSAL OF TOWNS' REFUSE.

BY W. M. WATSON.

(Concluded from last issue.)

Lately the scientific journals of the United States have been reporting a process of garbage disposal invented by a person named Harris. I visited his experimenting room and examined the garbage gas manufacturing machine, consisting of an extra large wood burning box stove, covered by two iron tubes, which acted as retorts for carbonizing the garbage, with another tube on top of the two, which answered for a superheater or reburner of the gas after leaving the retorts. I saw four lights of gas burning, stated to be from the gas manufactured from the garbage in the retorts, but after reading the description published on page 170 of the October issue of THE CANADIAN ENGINEER, I feel almost certain that the gas I saw burning was made from the coal oil, and, probably, chemicals that were mixed with the garbage when charging the retorts. I do not believe that Mr. Harris has found a chemical that can work what should be called a miracle, supposing that the reports should be true. A fuel gas can be made from vegetable or woody garbage that would add a great quantity of heat to a fire composed of wood or coal fuel, but would make a poor show if depended on to give heat or light alone. But even this kind of gas can scarcely be made with the little heat that can be generated with the experimental box stove, and I base my opinions on a two years' experience in the manufacturing of illuminating gas from sawdust, and the lessons I received, teaching me how to make water gas, and when I have explained the two methods, my readers will be able to judge the soundness of my views.

If ten pounds of melon skins and potato peelings be properly dried until all the moisture is extracted, it will be found that the vegetable substance left will weigh under 3½ pounds, proving that there was 6½ pounds of water in them, so that there is 3½ pounds of vegetable that can be made into fuel gas by a heat at a temperature of about 2,000° F., and 6½ pounds of water that can be made into a good heating gas, by first converting the moisture or water into a high pressure steam, then passing the steam through red-hot pipes which super-heats it, making the steam gaseous, then discharging it on to a fire heated to a temperature of about 3,000° F., in fine small jets, it is then turned into large volumes of gas, and by allowing drops of coal oil to drop on to the fierce fire along with the fine sprays of gaseous superheated high pressure steam, a passable illuminating gas is made at about the third of the price Harris declares he can make gas from garbage. In making gas from sawdust, we carbonized sawdust that was first dried well upon hot plates; if we needed illuminating gas we carbonized pine wood sawdust containing plenty of resin, which was probably the substance that gave out most of the gas needed. If we were well stocked with gas, we then carbonized dried hardwood sawdust that made large quantities of valuable acids; but we could not use wet sawdust to advantage, no more can Mr. Harris use wet garbage to make gas, for the two materials have a similarity. If we used sawdust in an undried state it condensed watery acids and threw off a

gas, useful only to burn under the cast iron retorts along with the bunch wood. So, plainly speaking, Mr Harris cannot make a combined vegetable and water gas with the heat that can be got out of wood burning box stove, because the heat needed to make gas from watery vapors would melt both his stove and his iron retorts, and the gas got from vegetable refuses will not be profitable to manufacture into illuminating gas.

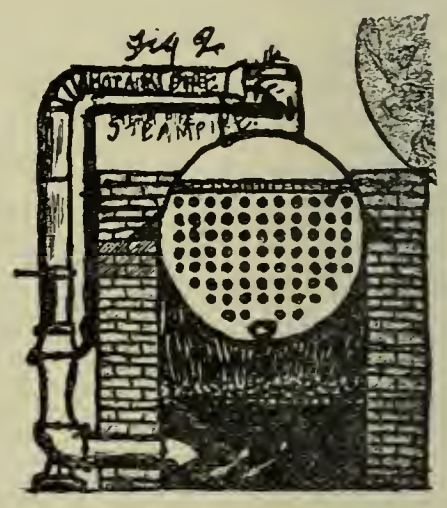
The scientific papers of Great Britain make fun of the reports published in the United States about the garbage gas invention, and laugh the project out of court, saying that the reports read like fairy tales. There is a sarcastic article on page 522 of the *Surveyor*, printed in London, Eng., Nov. 5th, that handles Mr. Harris' reports of his invention without gloves.

It is in order for the inventor to prove that he has found a chemical that will totally change vegetable substances and give them a virtue equal to coal that has taken the earth thousands of years to instill into its nature the gas and heat-giving properties. When that can be done I will gladly welcome the invention.

In Bradford they destroy bad meat and fish by a machine similar to a boiler, that possesses a steam jacket, and revolves, and is evidently filled with knives, for after the wet meat has been in and revolved about an hour, it runs out through a small hole in a fine dry powder, of great value for fertilizing, and the residue of the furnaces is manufactured into mortar, etc. They also find a paying market for every castaway found in and picked out of the rubbish. With the heat evolved they generate electricity and supply power for useful purposes. At Southampton they have lately set in a few extra furnaces of the Goddard, Massey & Warner's type, with forced draught appliances, making them capable of burning 15 tons a day. Multitubular steam boilers are erected on the top of these furnaces that generate steam to a pressure of 160 lbs., which is used to pump and turn the machinery that chemically treats the sewage of the town. The boiler being placed on top of the furnaces will cause the hot gases to have a continuous rising grade from the furnace to the chimney, while in other destructors the gases drop down several feet from the combustion chambers to the underground flue, often as much as 15 feet. This system will be highly satisfactory to engineers, who believe that bending and dropping the flues, and compelling the smoke and heat to go down hill, spoils the draught and wastes the heat. The destructors at Rochdale are somewhat different to the others, being fired by hand through the clinkering doors at the front, similar to the Lancashire boiler. This has the advantage of its being possible to spread the refuse evenly over the fire and of the proper thickness to insure quick combustion, destroying a larger quantity of refuse than those that are fed from the top, but, on the other hand, the objectionable stuff has to be tipped on the ground floor in front of the furnaces, in place of on top out of sight of most of the attendants, and where the smell can be least perceived. The boroughs of Dewsbury and Warrington have the high temperature destructor furnaces designed by Beaman & Deas, which supply the largest number of units of heat, and a small residuum of well-burnt clinker and ash. They create a great heat from the foulest refuse and garbage that can be handled, supplying a greater amount of heat per lb. of rubbish consumed, besides completely destroying the poisonous fumes usually thrown off when burning excrement, offal, etc.

These furnaces are built in pairs, the fire bars being horizontal, at the rear end there is a sloping, inclined, drying hearth and it has the feeding door at the back end, where the refuse is usually thrown in by hand labor, and when the fires are cleaned and clinkered at the front doors, the refuse which has dried with the heat from the furnace during the time it has been lying on the drying hearth slides down on the top of the fire. There is only one combustion chamber to each pair of fires. Each fire is fed and cleaned alternately, so that when one fire is newly charged with green refuse, and consequently at its coolest period the twin fire is at its highest temperature, and both having to deliver their discharged smoke and gases into one and the same combustion chamber, the high temperature of the one mixing with the low temperature gases of the other, reburns it and raises it up to a high temperature. Thus, the combustion chamber remains at a white heat, which fully destroys any unconsumed fumes of foul gas that may be cast off by the furnaces. A suitable fan is used to create a forced draught which delivers the current of air into the closed ashpit, thus the air is forced pretty evenly between the grate bars into the body of the fire. The crown of

FIG. 1.



the arch over the fire, called the fire screen, being the partition between the furnace and combustion chamber, is perforated with holes near the front, over the cleaning door, for the escape of the smoke and gases, which compels the fumes from the roasting refuses on the drying hearth to pass over the fire from back to front before entering the combustion chamber. Perhaps the most advantageous and valuable feature of this destructor is the hollow firebrick fire-bridge that forms a passage of atmosphere air from the outside to the rear end of the combustion chamber, where it enters through a quantity of small distributing holes, adding a quantity of warm air to the fiery gases entering the chamber, supplying them with the oxygen needed at that point to reburn and increase the temperature of the gases sufficiently to thoroughly burn and purify the obnoxious fumes. It will be obvious that the cold air passing through the fire bridge must pick up a large quantity of heat by radiation and enter the combustion chamber at a moderate temperature. It is stated that the clinker comes as low as 25 per cent. of the weight of refuses destroyed, while the slow combustion only reaches 33 per cent., a difference of 8 per cent., which means a great deal in the cost of cartage where the residuum of the furnaces has no handy way of being disposed of or manufactured into mortar slabs, paving brick, etc., etc.

This type of destructor has been improved upon in several ways, viz.: In place of using a cold air fan, which chills the fire at the point of attack, cooling the clinkers and causing them to stick to the grate bars, a combined steam and warm air blower is used similar to the steam blower mounted by R. S. Earl, of Toronto, over ten years since, and employed by many steam users in Canada and United States. It consists of a bunch of fine steam jets discharged into about a 9-inch tube, something similar to

Fig. 1 and Fig. 2, which shows the blower in the act of giving a forced draught to a steam raising boiler. This will help to explain how the machine acts in this kind of a destruction furnace. It shows that the supply of air in that case is drawn by the exhausted steam jets from over the heated boiler, and mixing with the hot steam in the ashpit, where it enters the furnace between the bars at a high temperature, without the least shock or cooling effect to the outer edge of the body of the fire. When applied to a destructor furnace the air and steam is superheated on their way to the ashpit from the blower, by passing through the hollow, square cast iron tubes that form the side walls of each furnace (see Fig. 3 and 4.) The steam blower is fixed in position at the side of the inclined drying hearth (see Fig. 4), and at the point where it enters the hollow walls. Arrangements are made to draw off the fumes discharged by the roasting refuse, forcing them into the ashpit to be passed through the body of the fire, which thoroughly cremates them. It will be seen by the sketch that the blower exhausts the foul air both from the tipping floor, where the men stand to charge the furnaces, and the drying hearth behind the fire, thus making the handling of unhealthy and disagreeable excrement or offal almost as healthy as ploughing a field, besides giving a strong forced draught to the fire, saving the expense and doing double the work of a tall chimney. The firebrick sides of furnaces are usually the place where repairs are oftenest made, and it is an improvement to have hollow iron boxes, because they form a passage for the steam and air, which prevents them from ever getting red hot and burning out, as all firebricks appear to do at this point, therefore besides being of material use, they also save expense and annoying stoppages, but on the other hand they will have an acute chilling effect on the fire, which is made up again, by extra efficiency and power of the steam draught, and the extra units of heat made from the chemical combination

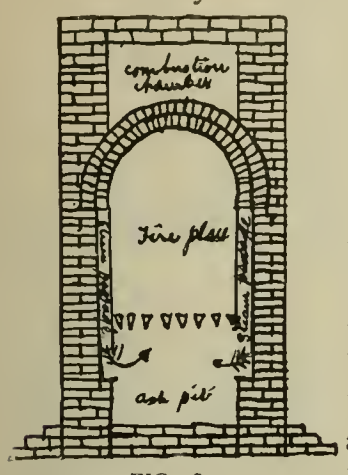


FIG. 2.

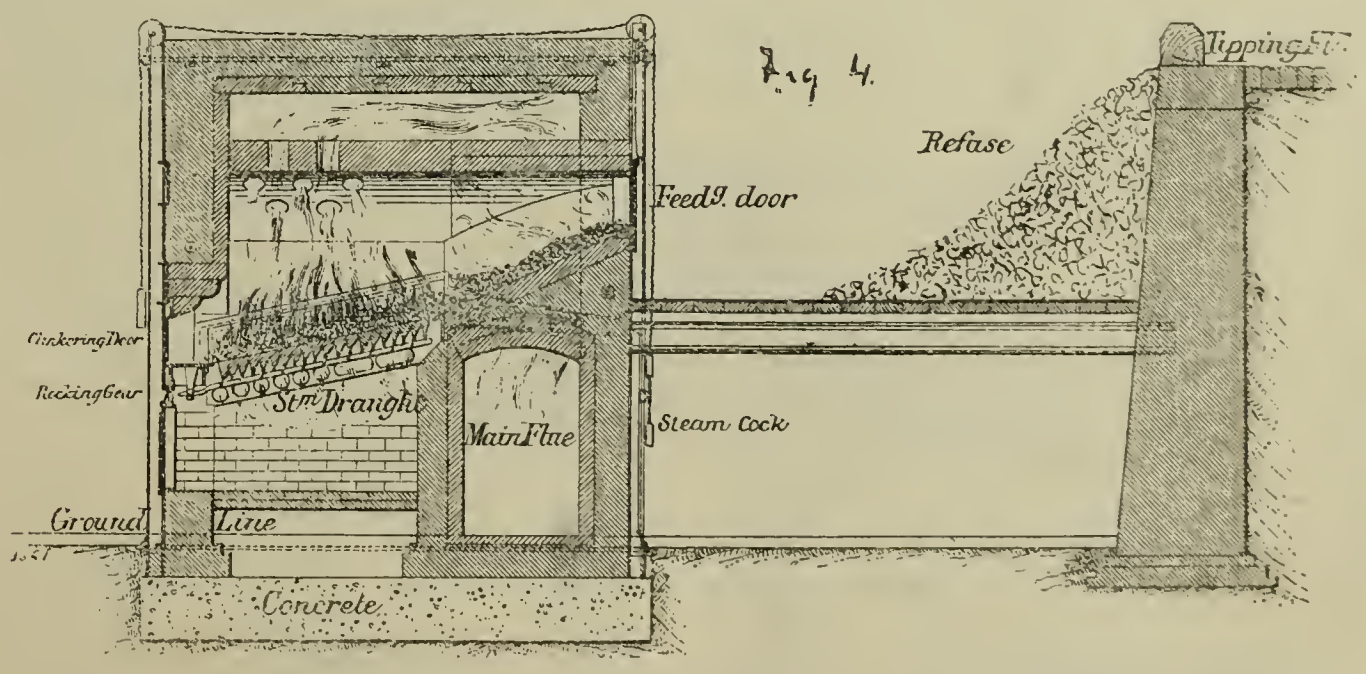
of the steam and the burning material. At Oldham, Hamburg and other places these improvements are in full working order. They are patented and controlled by the Horsfall syndicate, even to the rocking bars and steam blower, which are purely American. The cost of construction and full equipment is about $500 for each cell or furnace, when the number of furnaces built exceeds four in a block.

It will be noticed that the Beamans and Deas plan of building the furnaces in pairs, each joining with one combustion chamber, and the introduction of oxygen into the combustion chamber, are advantages that go far to counterbalance the improvements controlled by the Horsfall syndicate. In other points they are similar in build, and if the good points of each could be combined, a unique and powerful destructor would be produced. In European towns that have a close packed and dense population they have as many as thirty furnaces grouped together in a circle or other convenient design, having a large secondary combustion chamber or vault that receives the flues from all the first and separate combustion chambers; the walls of this vault get red hot and assist in again mixing and reburning the gases, thus for a second time increasing the temperature and purifying the gases cast off by the refuse and offal of each furnace. The annexed illustration (Fig. 4) shows a sectional elevation through a Horsfall furnace with the latest improvement attached; Fig. 5 shows the position of the ten furnaces in the small town of Oldham, England. The chain governing the steam valves that cut off the steam from the blowers when the man desires to open the front doors is shown passing over the head of the furnace and hanging down to a convenient point. The fire screen, the combustion chamber, the drying hearth, the rocking fire bars, and the route that the smoke and gases are compelled to take are all clearly shown to the point where they enter the flues on their way to the general collecting vault, from which they are conveyed to the boilers which generate steam, that creates power to run any kind of machinery necessary to do the power business of the town, and the temperature of over 2,000 deg. Fahr. is reduced to about 600 before it enters the chimney, which may discharge the purified gases close to the windows of a closely built district, without the slightest injury to health or contamination of the atmosphere.

We are told by parties that have visited and investigated the details of construction of every kind of destructors at present working in Great Britain, that the managers, the inventors and attendants of each kind assure the visitors that their system is by far the best, and point out the advantages, showing high-class testimonials,

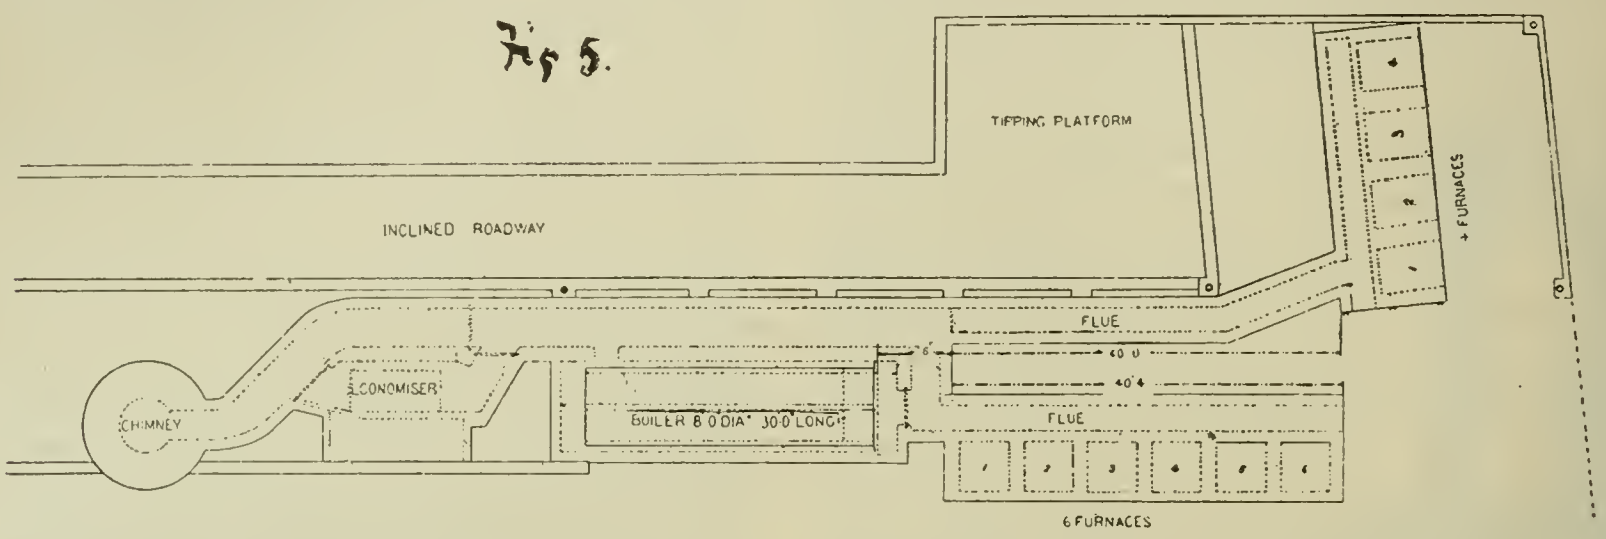


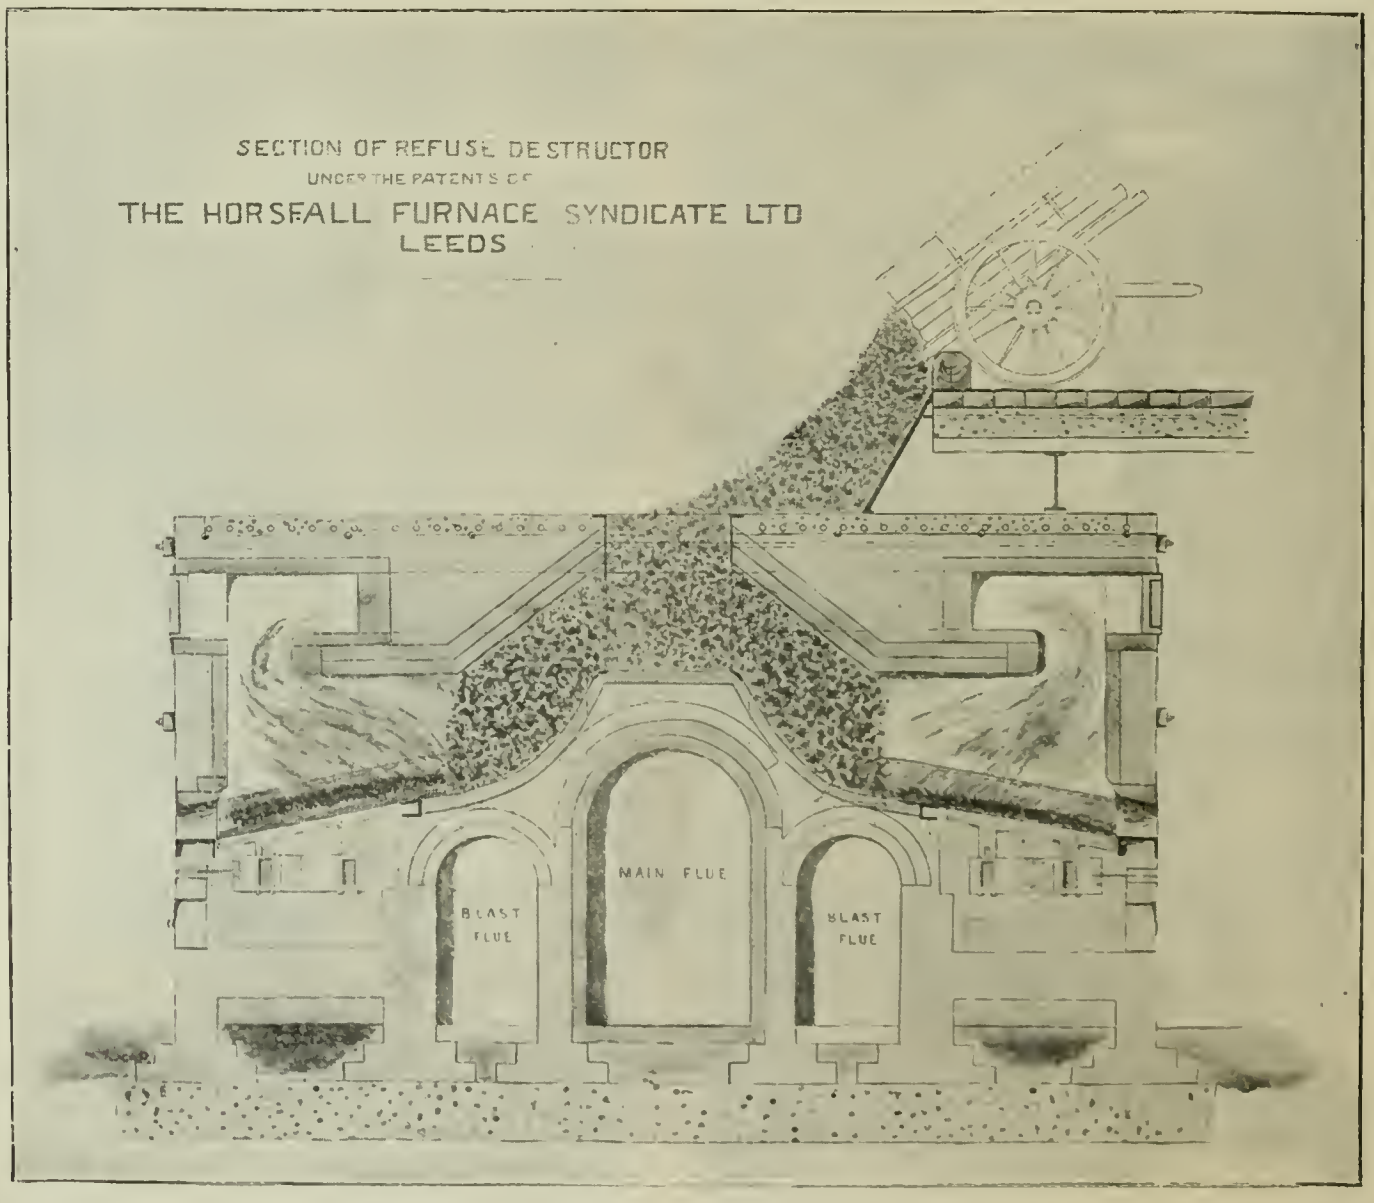
besides many pages of praise written in their book by previous visitors, which goes a long way towards mystifying and misleading deputations seeking knowledge. Those using the slow combustion and low temperature class, point out that one man can attend to fifty per cent. more fires than the men who attend the high temperature furnace, which may be true, but it is also true that the man attending to two high temperature furnaces consumes thirty tons of refuse each day, while the man who attends three low temperature fires, or one more than the other man, only

destroys twenty-one tons, or nine tons less than the man that only attends to two high temperature forced draught fires, so that their plausible argument is ridiculous when worked out in figures. They have a more combative objection, they say that the high temperature furnaces will soon burn out and the repairs will come high and expensive. Past experience of the few years that high temperature furnaces have been in use continually does not bear out the statement, for they remain sound and whole in places where they were well and properly erected, proving this argument wrong. The slag that attacks the brick in high temperature furnaces, and often believed to be caused by melting and running of the fire-brick, appears to have been proved by experts and experiments, together with careful watching during the past three years, to be silicious particles produced by the burning refuse and forced by the blast against the brick work, and can be easily knocked off. They also assert that it protects rather than damages the walls; this information is very satisfactory, and it is to be hoped that some person will find out a way of reducing silicious matter to either a powder or a gas, so that it will cease to be troublesome because it is a non-conductor of heat, and any combustion chamber lined with stalactytic formation will be useless as a re-burner of fumes and gases.

The solid advantages of high temperature furnaces is, that they burn all the fumes and injurious gases, without the aid of an expensive fuel eating cremator; they extract more heat, they reduce the refuses to the smallest possible weight and bulk, they make a harder and better clinker, they extract more heat per lb. of refuse and do double the work of the slow combustion type with less labor. Most of the low temperature sort are being altered and a forced draught added, making them into high temperature destructors, some of them on account of complaints that the unburnt fumes being discharged from their chimneys are a public nuisance. Before closing the subject of refuse disposal of towns, I might describe a useful refuse or house garbage destroyer, that if well built and carefully attended to when in use will be useful and valuable to any high-class residence or public building, placed in a country position where they cannot have the comforts of modern sanitary appliances, except they construct private ones for themselves. And where such places have their own private drainage and sewage disposal works this simple garbage destructor machine seems necessary to prevent the grosser solids, paper, grease, etc., from passing forward to the sewage settling tanks and choking the valves and pipes. The illustrations here produced, together with the explanatory references, will go a long way to

Fig 5.





explain the working of the machine. The apparatus consists of a series of perforated swinging buckets, holding about 1½ cubic feet, hung on a cross-bar, which holds in position the arms radiating from a central shaft similar to the Ferris Wheel. They are enclosed in an air-tight case, which has a connection by an iron pipe to a chimney and a 4-inch iron soil pipe that bring all the excrements and

Fig. 6

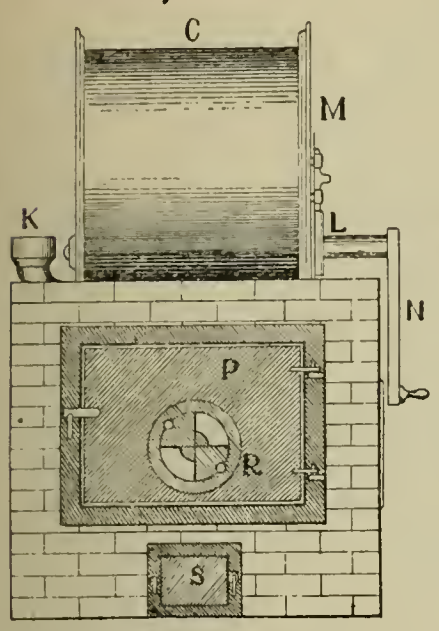


Fig. 7

A A A are the buckets or baskets of about 1½ cubic feet capacity *B B B* are the arms supporting buckets. *C* is the casing resting on an 8-inch wall *D* is the opening and thimble to connect to chimney. *E* is a grease trap made of common tiling. *F* is the grates. *G* is sand or clay filling. *H* is sewer pipe. *K* is cast iron intake pipe, *L* is ratchet wheel. *M* is the pawl to engage with ratchet to hold buckets in place. *N* is the crank arm. *O* is a door to get to grease trap. *P* is large door for access to buckets. *R* is a damper to regulate drafts. *S* is the ash-pot door.

sewage made in the building to the swinging buckets, together with the house garbage (except coal and wood ashes), which all fall and enter into the lowest bucket. The lowest bucket is securely held under the soil pipe, and when one is filled with the grosser solids, the attendant turns the wheel a notch, raising the full bucket up out of the way and leaving an empty one under the soil pipe. By the time the sixth bucket gets full the first is dried by the current of air circulating through the machine by way of the fire bars and chimney. The machine is so constructed that the sludge cake is easily turned out into the fireplace and the bucket swings back into its place. When the furnace place gets full with dry cakes, they are set on fire and quickly burn by themselves, and at the same time dry the contents of the six swinging buckets. If this cremator could be fixed near but outside of private buildings, it would answer for isolated places. There will be some smell from the machine, and the fumes from the burning sludge will pass out from the chimney when the sludge cakes are burnt about once a week, but the contrivance seems the best in sight yet for country places, and a great improvement on the present system in use.

A large number of towns dispose of their rubbish by sorting and cleaning that part of the rubbish that cannot be made into a manure, using the carbon and inflammable material for generating steam, and to enable the sorting to be done in a healthy atmosphere and without soiling the dresses of the employees, the best and latest designed machinery is used. By so doing, the cost of collecting the refuse is about covered by the sale of the products. Most of the cities and towns adopting this plan also adopt the pail system of privies, in place of vault privies, and very few water-closets are in use, because, having a well-disciplined army to regularly go around once a week or oftener to remove the full one, clean the place of lodgment out, and replace a well cleaned, disinfected pail, the places are kept sweeter and healthier than 90 per cent. of the water closets in use, and the sewage of the town is easier handled, being almost void of excrements. There are also towns which have the dual system of manufacturing manure and selecting out salable castaways, also destructor furnaces to consume the most objectionable offal that is collected.

Whatever system is adopted, the success and healthful efficiency almost entirely depends on cleanliness and well-disciplined management.

For THE CANADIAN ENGINEER.

WATER MAIN CLEANING IN ST. JOHN, N.B.

BY W. MURDOCH, C.E.

There are three leading mains supplying the city of St. John, N.B. Number one, 12 inches in diameter, was laid in the year 1851; number two was laid in 1857, and has a diameter of 24 inches; number three also twenty-four inches diameter, was laid in the year 1873. The reservoir from which the city's supply is derived is an artificial lake on Little River, distant five miles from the summit of the city and 160 feet above the level of high water in the harbor. The summit of the city is 130 feet above h.-w. datum, and the hydraulic gradient in summer time generally reaches this district at an elevation of about 145 feet, the fall being thus about 15 feet, and the head of water 15 feet. In winter this head of 15 feet has been known to disappear during lengthy periods of zero weather when water was being wasted to prevent freezing.

The two older mains had become so foul through internal incrustation that, when No. 3 was shut off for repairs and the city depended on the other two pipes, all the portions at a height of 80 feet or more above datum, comprising an area of about 200 acres and containing a population of about 8,500 souls, were without water. On the other hand, with No. 2 shut off and supply coming by Nos. 1 and 3, every pipe was full and water delivered at a level of 130 feet. This was an ample demonstration of the foulness of the old mains as compared with that last laid. In the summer of 1897 the common council passed an order directing that the mains be cleaned, and preparations were forthwith begun.

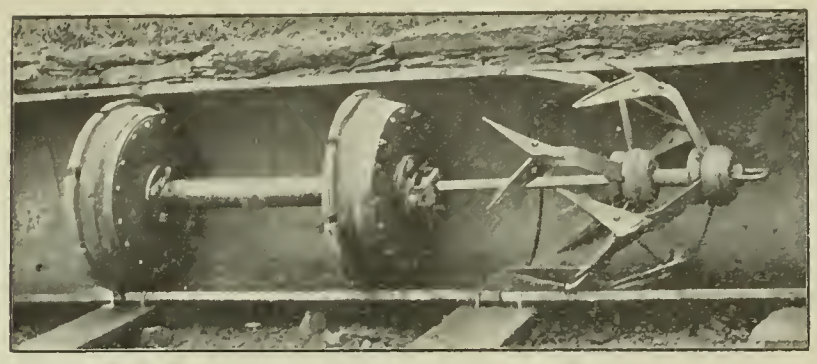
There being no hatch boxes on the main lines, such fittings had to be designed and tenders asked for their manufacture. James Fleming being the lowest bidder, he was awarded the contract at two cents per pound. Delivery began in the month of October, and the work of cleaning No. 2 was started soon after. In designing the cleaner or mechanical scraper, special precautions were taken to avoid the misfortune of having it lodge in the pipe with such consequent vexations, searchings and cuttings of pipe as have often occurred elsewhere. The desiderata laid down were:

a. That the apparatus be as light as possible, so as to

be easily projected up ascending gradients by the pressure of the water, and to offer generally as little resistance as possible whether through inertia or otherwise.

b. That as it is more desirable to take light cuts and make frequent runs, than attempt to remove all the dirt at once and have the scraper stick; therefore, the pistons should be so loose as to permit a free escape of water to carry off the loosened dirt in advance of the cleaner, and that the arms be not so rigid as to hold it up against any hard and abrupt obstruction encountered.

With these maxims in view, the machine was made as shown in the accompanying cuts, the pistons being



MECHANICAL SCRAPER, USED IN CLEANING ST JOHN, N.B, WATER MAINS.

of birch set in layers, each layer being one inch in thickness and placed crosswise of the other to prevent warping and increase the strength of the piston. Leathers were secured to the piston by means of an iron ring bolted against them, the bolts running through the piston. The spindle connecting the two pistons is of 3-inch wrought-iron pipe with a cast-iron flange screwed on each end and pinned over with a hammer to prevent the screw backing out. These flanges are each bolted through the piston to another flange on the opposite side. Projecting beyond the forward piston is an iron rod fitted with two sets of radial arms sloping back as shown in the cuts. There are four arms in each set made of No. 10 (B.W.G.) spring steel two inches wide, and each fitted with a forged steel scraper on the end, of the form shown in the drawings. The long sloping fish-tail form of this scraper enabled it to glide safely over every obstruction. In making the first runs, only one set of scrapers was attached; but in the latter, the whole eight were in use. This precaution was taken for the reason given, viz., lest a large amount of dirt should be loosened at once, and the cleaner become buried and stop.

A section of No. 2 main extending from the reservoir toward the city, a distance of about 6,000 feet, having been prepared by inserting a hatch-box at each end, the work of cleaning began on October 12th at 1 p.m., and was continued that afternoon. The head of water upon the upper hatch-box was 20 feet and on the lower 27 feet. The first run took four hours, for the reason that a cord sufficiently long to reach the whole length had been placed on a revolving drum 10 feet in circumference, and furnished with an indicator to register the revolutions. The end of this string was attached to the cleaner, and a record kept of its location as it sped along. But when the first flushing branch was reached the twine drifted out here and down the brook, while the drum kept on revolving and the indicator registering until the whole string was paid out. Meanwhile the cleaner had become securely moored near the flushing branch and could not be liberated until the stop-cock was dug to and uncovered. On the twine being cut and pulled out and the stop-cock lid restored, water was let on again and the cleaner finished its journey, a distance of 2,200 feet in about five minutes. This first run was sufficient to show that twine was dangerous, and we also learned that it was entirely unnecessary, for the grating sound of the cleaner as it passed through the pipe was heard quite distinctly by the two watchers under their feet as they followed the sound along the line. Two more runs were given that same afternoon, the time occupied to go the distance being about twenty minutes. The water was inky black for some time as it flowed from the flushing pipe, and it was allowed to run for two hours after the cleaner had been removed, this time having been required for the water to clarify.

The next section was taken on Saturday, October 23rd. It extended about 6,600 feet cityward, but in order to give the first section another scraping it was concluded to insert the cleaner at the dam and run it through the entire $2\frac{4}{10}$ miles. A misfortune was met this time in the following manner: The leathers having worn out during the first cleaning were renewed with a harder and stiffer quality than formerly, but they repeatedly caught in a new joint made while inserting the hatch box. Each time the lid was removed to ascertain why the cleaner did not start, it was found firmly fixed by this imperfect butt of the two pipe ends. After twice extricating it and again finding it caught in the same way, a jack-screw was applied to push it past this obstruction, the lid was again put on and the water let in at 4.05 p.m., and this time it started. At each of the five flushing stations the gate was left open fully ten minutes after the cleaner had passed, and then closed. As soon as the gate was closed the cleaner again proceeded, and the scraper, with only one piston, reached the end of its run at 5.25 p.m., having been one hour and twenty minutes going 2.4 miles, but when 50 minutes of a total stoppage are reckoned, the machine was found to have been in motion 30 minutes. As stated, only the forward part of the cleaner arrived, and search had to be made for the remainder. Nothing was done on the following day, which was Sunday, the castaway piston, which was lying obliquely somewhere in the pipe, having but partially obstructed the flow, and the water was left on until the Monday night following.

A receiving chamber unites Nos. 2 and 3 mains near No. 3 hatch box, and they are controlled by stop-cocks on each side of the receiver. It was, therefore, an easy matter to reverse the current of water in No. 3 by closing the stop-cock at the dam, and opening that at the receiver, as well as the flushing branches. This was done, and men were distributed along the line to listen for a rumbling noise, which at length was heard within about a quarter mile of hatch box No. 3, from which the cleaner had been extracted. The sound was followed along the line toward the reservoir until hatch box No. 2 was reached, when the derelict was taken out, after having travelled nearly a mile and crossed a valley about 90 feet in depth. It was found that the pressure of the jackscrew in forcing the cleaner past the uneven joint had cracked one of the flanges, with the result that after having travelled about 2¼ miles the cleaner fell apart. The forward part, comprising a piston and the scraper, pushed on, but the spindle attached to the rear piston fell to the bottom of the pipe, ploughed up some dirt and finally became embedded and jammed. The reverse current striking the piston as it did, drove it back with the spindle trailing behind. The apparatus was repaired and three more runs made through this double section of 12,600 feet, on October 29th, without any further mishap, the time taken for each run, including ten minutes stoppage at each of the five flushing stations, having been from 1 hour 46 minutes to 1 hour and 55 minutes. The cold weather being on when

the next castings arrived, cleaning operations were suspended for the season, to be resumed next spring.

On testing the efficiency of the cleaned main by shutting off No. 3 from the reservoir to the receiving chamber, where both unite, and bringing the supply through Nos. 1 and 2, it was found that the pressure in the city was as good as when No. 2 was shut, and the whole supply coming through Nos. 1 and 3, thereby showing that the capacity of No. 2 had improved to such an extent that whereas, with No. 1 it had formerly delivered to a height of 80 feet only, when unassisted by No. 3, and left 200 acres of the city, containing 8,500 inhabitants, without water, now the whole city could be supplied without the help of No. 3 and the water rise to a height of 130 feet above high water. The general improvement in pressure with all three mains on was found to be about four feet. Nearly two miles of this line remain yet to be cleaned, after which the other two. pipes will be taken as soon as the coming season permits

For THE CANADIAN ENGINEER.

TORONTO MAGNETIC OBSERVATORY.

BY R. F. STUPART, DIRECTOR OF THE OBSERVATORY.

The importance of obtaining a correct knowledge of the elementary facts of terrestrial magnetism, for the purpose of supplying a foundation whereon the advancement of that science on inductive principles may be based has for long been strongly and extensively felt.

From an early period of the meetings of the British Association for the Advancement of Science, the interest of terrestrial magnetism had received no inconsiderable share of the attention and exertions of its members. In the year 1834 a magnetic survey of the British Isles was commenced and carried through in the two following years by the joint labours of five of its members. In 1835 the association called for a report from one of its members, on the state and progress of researches regarding the geographical distribution of the magnetic forces on the surface of the globe; proposing to ground on the preliminary examination an application to the Government to aid in the prosecution of the enquiry in remote parts of the earth, unattainable by the means at the command of the association itself or of its individual members. This report, presented in 1837, was taken into consideration at the meeting of the association, at Newcastle, in 1838, and a memorial was addressed to the Government which, being favorably received by Her Majesty's Ministers, originated the naval expedition equipped in the following year for a magnetic survey of the high latitudes of the southern hemisphere. Deeming the opportunity a fitting one, the British Association availed itself of the same occasion to solicit the attention of Her Majesty's Government to the expediency of extending the researches to be accomplished by fixed observatories to certain stations of prominent magnetic interest within the limits of the British Colonial Dominions; the stations named were Canada and Van Diemen's Island, as approximate to the points of the greatest intensity of the magnetic force in the northern and southern hemispheres; St. Helena, as approximate to the point of least intensity on the globe, and the Cape of Good Hope as a station where the secular changes of the magnetic elements presented features of peculiar interest.

The committee recommended that the proposed colonial establishments should be placed under the general supervision of the Ordnance Department of the Army. The Government having expressed a desire that such extensive arrangement involving a considerable expenditure should be strengthened by the concurrent support of the Royal Society, a deputation was appointed to express the cordial participation of that society in the recommendation both of the Naval Expedition and of the fixed observatories. Arrangements having been completed, Lieut. Charles James Buchanan Riddell, R.A., was selected for duty in Canada, who, leaving his detachment, consisting of four non commissioned officers of the artillery, to embark with the instruments on a vessel bound direct to Quebec, proceeded himself to Canada by the more expeditious route of the United States; and having waited on the Governor-General at Montreal to present a letter of introduction with which he had been furnished by the Master General of the Ordnance, and communicated with the Commanding Engineer, to whom he was the bearer of instructions and authority to build an observatory, he proceeded to examine different localities which were suggested as convenient sites. The preference was finally given to Toronto, where a grant of two and a half acres of land belonging to the University of King's College was offered by the Council of the University. The first observatory building was of logs, roughcast on the outside and plastered on the inside; it was completed during the summer of 1840 and observations were begun in September. The operations of the observatory as an Imperial establishment were brought to a close in the early part of the year 1853, and were resumed under the authority of the Provincial Government in July of the same year.

In the autumn of 1853 the present observatory was commenced, to take the place of the old building. Very great care was taken during construction to insure all the stone used being entirely free from magnetism, and all nails and fastenings were of either copper or zinc. For twenty-three years the position of the Observatory was as far as is known, faultless, and observations were carried on systematically and carefully, and results given to the scientific world, which with those obtained under the old military regime, have made the Toronto Observatory famous in the history of terrestrial magnetism.

In 1876, however, trouble began with the building of the School of Science, which institution, however, being principally of brick and wood, caused but very small changes in zero values, which could be allowed for. Then followed a few years later electric light circuits which produced a change in the force instruments whenever the current was turned off or on, this difficulty was in part overcome by the Light Company courteously agreeing to arrange their wires in the vicinity of the Observatory in such a manner that currents should counteract each other. The next difficulty occurred when the addition was given to the School of Science, tons of iron being used in the construction of that building in an all too close proximity to the magnetic instruments, and much time and labor has been required to determine the precise effect of this "iron mine" on the various instruments. It was not, however, until the autumn of 1892 when the trolleys began to run that we began to suspect that sooner or later the Magnetic Observatory would have to be removed to another site.

The magnetic instruments in the Observatory consist of those brought out by Lieut. Riddell in 1840, of which eye readings have been taken six times each day, and of another set of similar instruments consisting of a bifilar for the measurement of the horizontal component, a balance needle for the vertical force and a declinometer, all of which record photographically.

Electric cars first ran in Toronto on August 17th, 1892; the line first put in operation was that on Church street, which was followed on September 5th by King street, between George street and Dufferin street. During

the first few weeks, while a very small vibration of the needle was discernible on the V. F. curve it was generally almost inappreciable, and it was not until September 20th that the movement increased to an extent sufficient to really impair the value of our magnetic curves; a marked increase of current must have been used on that day and afterwards. On October 10 the cars first ran on Yonge street, and there was only a very small increase in vibration, but a decrease of about .000070 of a dyne was observed when the current was on. About 10 a m., on the 14th January, there was a marked increase of vibration, and the vertical force increased about ·000200 one dyne. This disturbed period was only temporary, and shortly after 5 p.m. of the 17th there was a reversion to the smaller vibrations, which continued until May 15th, when very large vibrations began again and continued with varying intensity during the summer, while the decrease of the V. F. with the current ranged from about ·000200 to ·000500. This disturbance was very great between September 12th and October 17th and at intervals during the following year, but there was no radical change in conditions until December 17th, 1894, when a decrease of V.F. while the current was on, was changed to an increase, this occurring when the cars first ran on McCaul street. Throughout 1895 the vibration and amount of permanent deflection was very nearly as it has been since, but on October 15th the increase of V. F. with the current was again changed to a decrease, this occurred at the time that the railway company made certain changes in the feed wires. It is noticeable that although several changes occurred in the V.F., it at times having been less with the current on and at other times greater. The horizontal force showed a steady decrease on all occasions with the turn on of the current, which during the past two years has been ·000200 to ·000500. No appreciable deflection of the declinometer magnet can be noted, the only effect being a continuous vibration which has rendered the curves very ragged and difficult to read with accuracy.

A study of the traces during the times that the various electric lines were put in operation shows that with the currents ordinarily used there is little effect at $\frac{3}{4}$ mile, and a further survey with a portable instrument affords further evidence in the same direction; it has, therefore, been determined to remove the magnetic instruments to a point distant two miles from any probable trolley route and about nine miles from the present location, and continue what is certainly the most valuable and extended magnetic records outside of Europe.

NOTE.—The history of the establishment of the Observatory at Toronto is taken from the early reports.—R. F. S.

PROCEEDINGS OF THE THIRTEENTH ANNUAL MEETING OF THE ILLINOIS SOCIETY OF ENGINEERS AND SURVEYORS, AT PEORIA, ILLINOIS.

The Illinois Society of Engineers and Surveyors assembled in thirteenth annual meeting in the rooms of the County Superintendent of Schools, in the court house, January 26th. The executive secretary's report showed the society to have eighty-one old members in good standing, and during the course of the meeting twenty-two new members were added. After the secretary's report had been read, C. C. Stowell, president of the society, delivered his annual address. The report of the waterworks committee was presented by Dabney H. Maury, jr., chairman. This report gave information regarding the rules, regulations and rates of water companies throughout the State of Illinois. The secretary read a paper on "Railroad Construction in Mexico," by L P. Atwood, engineer of the maintenance of way of the Rio Grande, Sierra Madre and Pacific Railway. Mr. Atwood also presented a detailed account of the cost of steel tie plates used in the construction of this road. John T. Stewart, of Paxton, gave his experience as a leveler for the United States Geological Survey, in running lines in the Black Hills country. S. S. Greeley gave an interesting discussion upon the topic, "The Status of the Surveyor of Illinois; Is it a Profession or a Trade?" His conclusions went to show that surveying is one of the liberal arts; a profession, and not a handicraft or trade. He argued strongly for the licensing of surveyors and engineers, referring to the recent Act of the Legislature of Illinois requiring architects to be licensed.

The evening session, which was held at Bradley Hall, was given up to a description, with stereopticon illustrations, of the Peoria Park system, by R. R. Bourland, O. F. Du Buis and L. K. Dowein. The exercises were opened by an address of welcome by Hon. John Warner, mayor, which was followed by an address to the engineers by Hon. O. J. Bailey, president of the Polytechnic Institute. Before the opening of this session members of the society inspected the Bradley Polytechnic Institute. Thursday morning, Prof. Wm. D. Pence, of the University of Illinois, read a paper on the Graphical Representation of the Magnetic Declination, describing in a very interesting manner the daily and annual movements of the magnetic needle. P. C. Knight, chairman of the Drainage Committee, submitted his report on drainage and gave a description of the drainage of the Meredosia swamps in Whiteside county. Centrifugal pumps are used, having a daily capacity of 36,000,000 gallons of water per day with a lift of sixteen feet. An interesting paper upon the purification of sewage by the Ferozone Polarite System, as observed at Acton, England, was presented by John V. Alvord, Chicago. The discussion which followed the reading of this paper indicated that this system is to be adopted in the vicinity of Chicago at an early date. One of the most valuable papers which was presented to the society was on "Water Analysis," by A. W. Palmer, Professor of Chemistry at Champaign. Prof. Palmer being in charge of the sanitary survey of the waters of the State of Illinois, has much information upon this subject.

The afternoon of Thursday, the 27th, was devoted to an inspection of the Peoria water works plant and the Atlas distillery. At the evening session, Charles H. Nicolet, chairman, read the report of the committee on Municipal Engineering. A paper on Proposed State Supervision of Water Supply and Sewage Disposal was read by Jacob A. Harman. This paper gave a record of the efforts of the engineers and physicians of the State to have a bill passed providing that the State Board of Health should have control of the water supply and sewage of the State. The following officers were elected for the ensuing year: President, A. D. Thompson, Peoria; vice-president, W. A. Darling, Rock Island; executive secretary and treasurer, Jacob A. Harman, Peoria; recording secretary, J. C. Quade, Kewanee; trustees, W. D. Pence, Champaign; S. S. Greely, Chicago; C. C. Brown, Bloomington.

Friday, the 29th, the last day of the session, was devoted entirely to the reading of papers and committee reports and discussions. Prof. A. N. Talbot, of the University of Illinois, presented a report for the committee on paving brick specifications, and recommended that the society adopt certain uniform methods of testing. This report was finally referred back to the committee for further investigation to report at the next annual meeting. The first paper on the programme was "Deep Well Pumping," by E. E. Johnson, of Chicago. His paper gave very valuable data with reference to the air lift pumps and other systems of deep well pumping; he also exhibited a model of a new design of deep well pumping, which shows a great economy over any forms of deep well pump heretofore in use. S. S. Greeley, chairman, reported for the committee on the metric system, and a resolution was passed endorsing the adoption of the metric system for general use in the United States. Mr. J. E. Miller read a paper on "Brick and Macadam for Country Roads," describing work which had been constructed north of Monmouth, Ill. J. T. Schmeltzer, Mantino, read a paper on Improving the Roads of Illinois A most interesting paper on the road problem was that on The Improvement of Transportation in Country Districts, by E. E. R. Tratman, Chicago, resident editor *Engineering News*. A. Lagron reported for the committee on Public Highways, and showed a disposition to discourage action upon the subject by engineers because of the lack of interest exhibited by the farmers, or those who have most use for the roads. M. Huebinger, Peoria, presented a paper on City Map Making. After numerous resolutions, and installation of officers, the society adjourned.

AN Ontario charter has been granted to G B. Meadows, A F. Ede, Rose Ellen Meadows, May K. White, and T. Urquhart, Toronto, Ont; W. G. Meadows, Buffalo, N.Y., as the George B. Meadows Toronto Wire, Iron and Brass Works Company, Limited, to manufacture and deal in wire, wire-cloth, wire-fabric, wire goods, ornamental wrought iron-work, fencing, art metal goods, bank and office-railings, window-fixtures, display-stands, brass and brass goods, iron or wire-cots and bedsteads, elevators and elevator-coverings.

THE NEW WORKS OF THE TORONTO ELECTRIC LIGHT COMPANY.

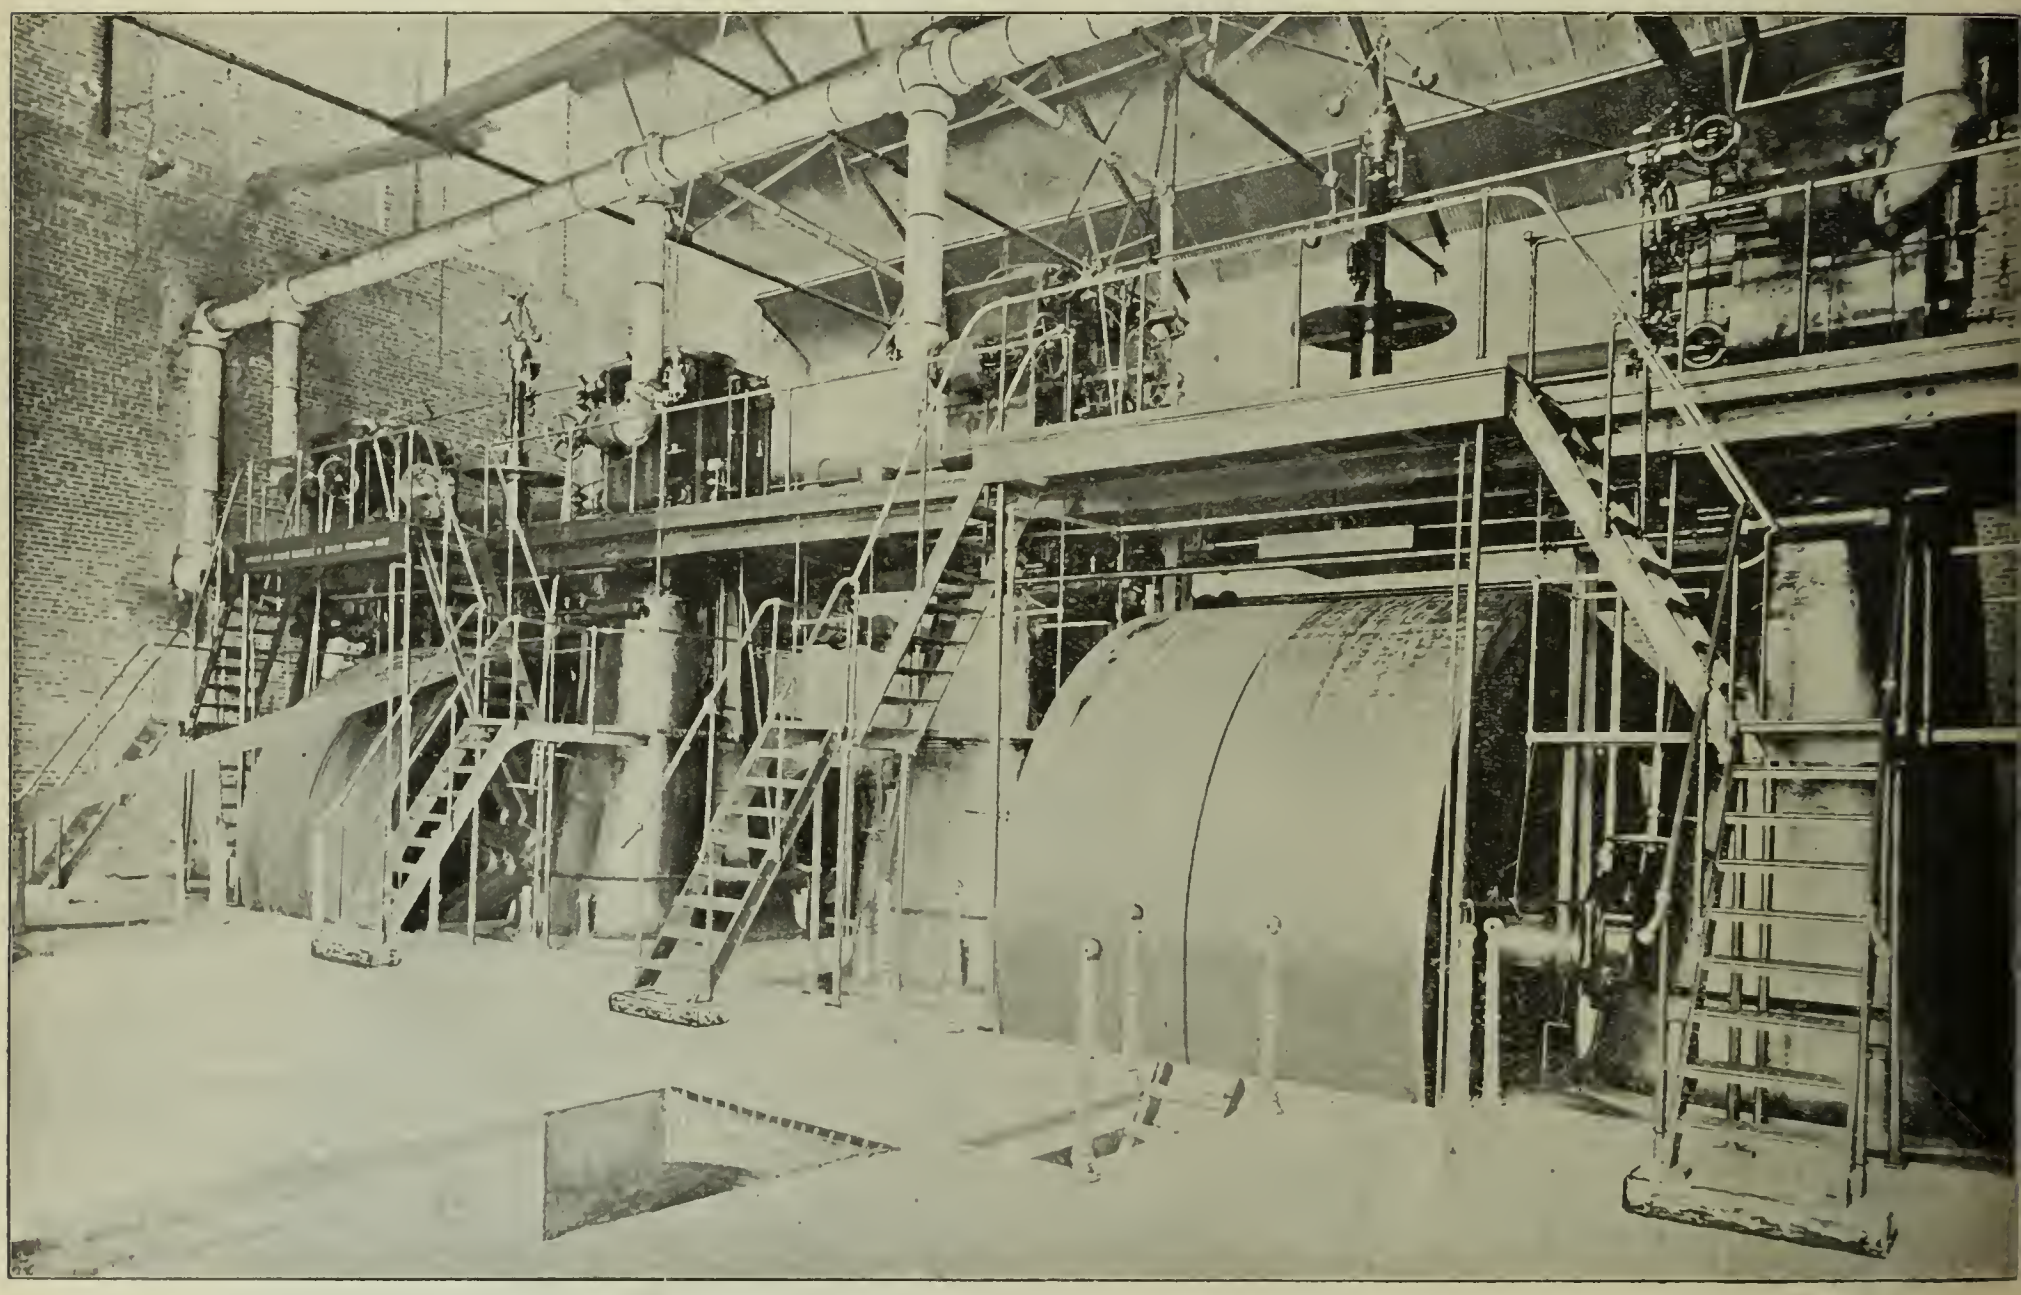
We are enabled in this issue to furnish our readers with some views of the new buildings of the Toronto Electric Light Company. It will be remembered that on the 21st of January last year, a destructive fire occurred, causing a loss of the arc lighting station of the company. Some effective work was done in providing temporarily for the illumination of the streets until permanent quarters could be provided for a new plant. The location of the works is one of the best that could possibly be chosen for a central distributing station. It is upon the water front of the city and at the foot of its principal thoroughfare and business centre. Unlimited water is available for condensing purposes and facilities for the unloading and storing of coal, both from cars and vessel, are of the best. In re-building it was determined to eliminate altogether the risk of loss and interruption by fire, and the new buildings are therefore constructed exclusively of iron, brick and stone. There is absolutely no wood used in their construction. The arc light station, No. 1, of which two views are shown, was completed about the first of September last, and is 165 feet in length by 68 feet wide. The foundation rests upon piles which were driven to the solid rock, and upon these a bed of concrete two feet nine inches thick was laid over the entire surface. Upon this the dynamos and engine foundations were build of hard brick and cement. They were raised high enough to permit of good head-room below, and the floor was formed of brick arches resting upon these foundations and upon I beams and iron pillars in the intermediate spaces. In the tunnels thus formed the driving shafts are placed. The dynamos are driven by belts passing through apertures in the arches to the floor above. There are in this building two compound condensing engines of 350 h.p. each, and two pairs of high-pressure condensing engines of 450 h.p. The shafting is all 6 inches in diameter, and runs on self-oiling bearings, being driven from the engines by triple leather belts 38 in. wide. A twenty-ton traveling crane is constructed to cover the entire floor space. This has been of the greatest value in placing the machinery in position, and when repairs are required, will be able to handle the heaviest piece of machinery at a minimum of both time and expense.

THE SCOTT STREET POWER HOUSE AND DOCK OF THE TORONTO ELECTRIC LIGHT COMPANY, LIMITED.

The arc light switchboard, which extends across one end of the building, is somewhat unique in both its methods and construction. It is built of pressed brick, with terra cotta facings. The terminals of the circuits are mounted on glazed tiles let into the face of the work. Ampere meters for each circuit are also mounted on other glazed tiles, and are large

enough to be seen from any part of the building. It is not necessary for the attendants to go to the switchboard, but they can see the state of the various circuits at any time, and wherever they may happen to be. Behind the wall constituting the board is a slate shelf, extending the entire width, to accommodate a standard ammeter or other testing instruments, which can be plugged in any circuit at any time by means of spring-jacks in each line. In each line also is a polarity indicator to ensure the correct direction of the arc lighting currents. The whole is surmounted by an electrically-driven cock, also built of brick, with a dial 6 feet in diameter.

Immediately adjoining this building, and forming the front premises, as seen at the left-hand of the engraving, is another fire-proof structure, which will be used as store-rooms for all kinds of supplies and show-rooms for incandescent fixtures, etc., and a completely fitted up meter department having all the latest appliances for repairing, reading and testing the various kinds of meters in use in the business. No. 1 boiler-house has re-erection. It is now a frame iron-clad structure, lined inside and on all the joists and timbers with sheet-iron. It is intended to replace it as soon as the weather permits with an iron and brick structure to match the others. The foundation work is now all completed and ready for the walls. As it is proposed to replace the building without interfering with the operations going on inside, considerable ingenuity will have to be exercised to avoid stoppage of the machinery for any considerable length of time. The building contains a double upright tandem condensing engine of 1,000 h.p., besides dynamos of all classes, arc light alternating and direct-current power machines, besides a pair of 110-volt machines that are supplying the underground mains of the Edison system in conjunction with the generators at the Teraulay street station of the company. At one end of the building is located the general switchboard controlling the entire output of electricity for all purposes. One attendant thus has under his hand the output from all the buildings except the arc light.



3,000 H.P. Engines in No. 3 Station, Toronto Electric Light Co

also been re-built, and has an iron roof with swinging sash for light and ventilation. This boiler-room contains three Heine water tube boilers of 250 h.p. each, and 10 return tubular boilers of 120 h.p. capacity each. No. 2 boiler-house, opposite, has two 250 h.p. Heine boilers, and two 250 h.p. Caldwell water tube boilers, with capacity for as much more.

Station No. 3 is a handsome fire-proof building, with iron roof and stained-glass windows. It is used for production of electricity for motor power and incandescent lighting. It contains two pairs of vertical Corliss engines of from 1,000 to 1,500 h.p. each. These are shown in the engraving. At the time the views were taken the ornamentation of the building was not completed. The brick walls which are shown bare, are colored a cream tint, with chocolate-colored dado and frieze. There are four dynamos only in this building, but they are machines of great capacity. Two of them being direct current 250-volt generators of 500 kw. each, and two double armature alternators of 450 kw. each. The air pumps of these engines are driven by independent Corliss engines, and make a very complete and satisfactory arrangement. The dimensions of this building are 80 feet by 68 feet.

Station No. 2, which is the building immediately in rear of the offices, shown on the right of the view, is now in course of

At the further end of the lot is a spacious wharf on which will be erected for the opening of navigation an extensive coal storage plant and electric hoist for unloading vessels. Adjoining this are the stables with accommodation for 30 horses, linemens' quarters, lamp inspectors' and trimmers' room, carpenter shop, store-house, blacksmith shop, and a commodious machine shop, where a large amount of manufacturing is being carried on, as well as all the repair work necessitated by the operations of the company.

When the contemplated improvements are finished, the entire installation will be one of the most complete and up-to-date to be found in the country. The entire work of re-building has been done by day labor by the employees of the company, even to the construction of the iron roofs. The design and execution of the various works are creditable to the management and the efficient staff having charge of the varions branches of the work.

While the air is charged with rumors of so-called "cheap power" and various schemes, "fake" and otherwise, are being promulgated, the Toronto Electric Light Company are steadily proceeding with their developments. They are, it is claimed, producing power at the present time quite as cheaply as it can be transmitted from Niagara or any water-power, and the con-

Switchboard End of No. 1 Arc Lighting Station, Toronto Electric Light Co.

templated installation of coal-handling apparatus to further reduce the cost will enable them to compete with electricity produced from any source. The rate at which power is being sold in Toronto, namely, 2 cents per horse power hour for 10 h.p., is said to be the lowest on the Continent of America to-day from a plant of a similar nature.

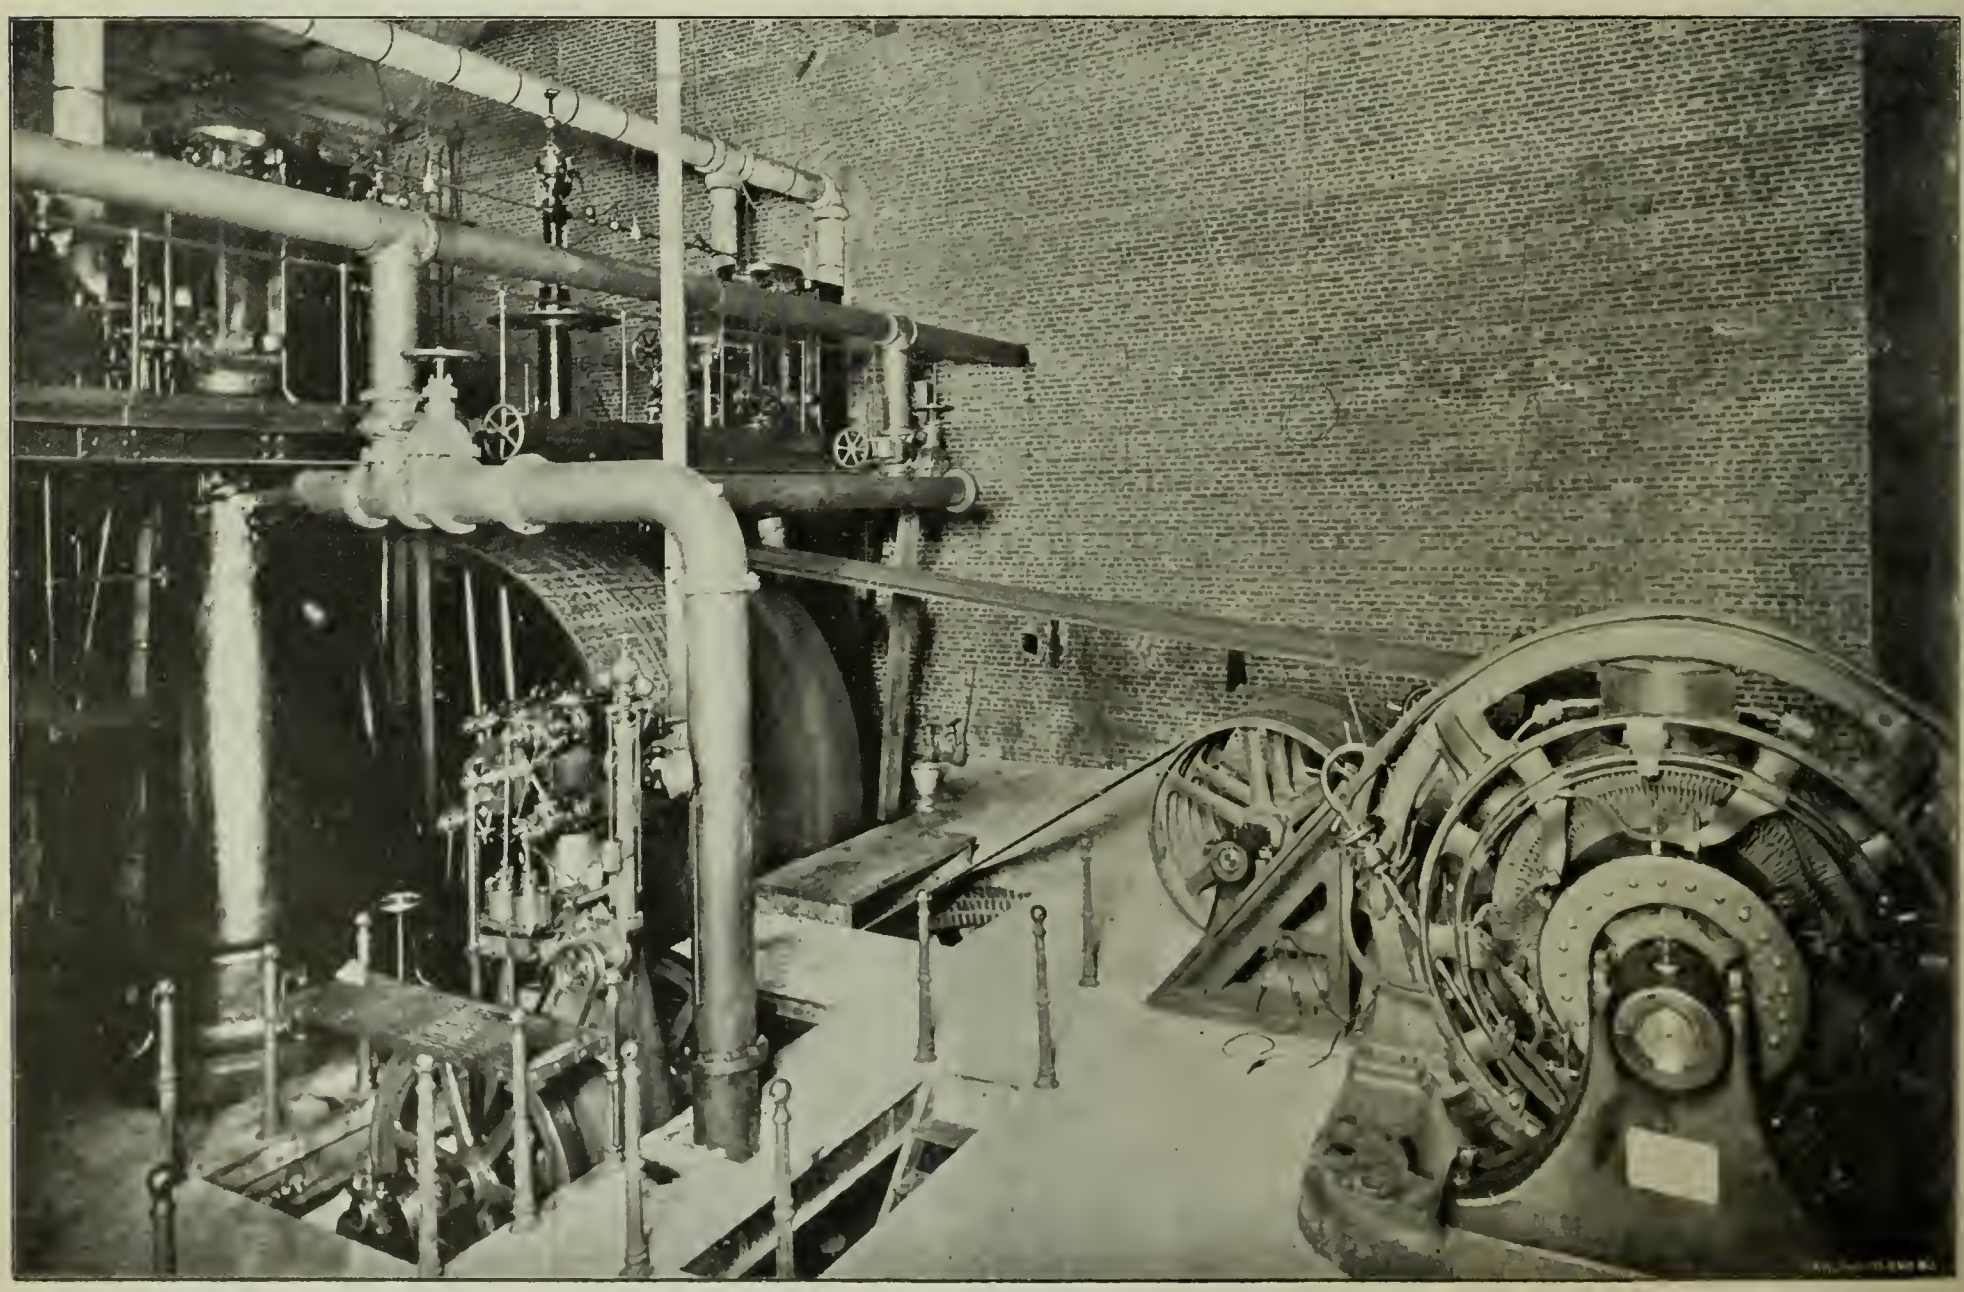
J. J. WRIGHT.

J. J. Wright, manager of the Toronto Electric Light Company, whose name is very well known in connection with the development of the electric lighting industry in Toronto, is one of the pioneers in the business of producing electricity for industrial use. He was born in Yarmouth, England, in 1850, and was educated at Shireland Hall, near Birmingham, and subsequently served some years at mechanical engineering. His father was a minister of the Methodist Church in England, but as he died while the subject of our sketch was but a youth, there were no ties to bind him to the Motherland, and Mr. Wright, like many others, in the early seventies struck out for the New World and landed in Canada some twenty-seven years ago. He went to Philadelphia at the time of the Centennial Exhibition of 1876, at which time electricity was beginning to attract attention as a commercial possibility. He there became acquainted with Professors Thomson and Houston, then members of the faculty of the High School at Philadelphia, and constructed for them some of the earliest experimental dynamos, crude enough in themselves, but the embryos from which have sprung some of the brilliant results of to-day. Mr. Wright constructed some of the first lamps used for street illumination, and was among the first to handle electric light wires in the construction of under-ground service, having constructed a line of under-ground wire for electric lighting in Market street, Philadelphia, between the City hall and Fourth street, in the year 1881. He was a member of the Franklin Institute of Science and Arts, and also a member of the National Conference of Electricians, convened by the United States Government.

In the spring of 1883 Mr. Wright returned to Canada and commenced the construction of the first plant for the distribution of electricity in this part, if not in the whole of Canada. It was located near the corner of King and Yonge streets, Toronto, and was the nucleus from which has sprung the extensive electric lighting interests of the city of to-day. When the Toronto Electric Light Company was organized the original plant was absorbed in the new company, and since that time Mr. Wright has filled the position of general manager. He has been three times elected president of the Canadian Electrical Association, and one of his most cherished possessions is a handsome gold watch that was presented to him at the close of his first year of office by members of the association.

Mr. Wright built and operated the electric locomotive that was for several years used at the Industrial Exhibitions in Toronto. This was the first electric railway in Canada, and during the years of its operation successfully carried many thousand of passengers. Mr. Wright was the recipient of an engrossed resolution and handsome testimonial from the Exhibition directors for the successful carrying out of what was then a new and untried service.

The design and construction of the new work of the Toronto Electric Light Company, which we illustrate in this issue, is Mr. Wright's latest work, and is one that has been most highly spoken of by more than one who is in a position to be a most competent judge.



DIRECT CURRENT GENERATOR, 250 VOLTS, 500 K W., TORONTO ELECTRIC LIGHT CO.

THE CHEMISTRY OF FOUNDRY PRACTICE.

BY ERNST A. SJOSTEDT.

Compared with the chemistry of the blast furnace process (in which the ores are deprived of their O., and the reduced metal combines with elements like carbon, silicon, manganese, etc.), and the different processes of iron and steel making (whereby the said foreign ingredients are oxidized and eliminated to a more or less complete degree), the chemical changes taking place in the cupola, where the metal is merely re-melted, are quite simple. Nevertheless, these changes, small though they be, are sometimes of great practical importance, and as the physical qualities of the castings (such as strength, hardness, elasticity, etc., are very largely dependent on the chemical composition of the metal, it is evident that the adaptation of chemical researches in connection with the foundry practices are well deserving of a most careful attention. The importance and necessity to the blast furnace manager and the steel worker of applying chemistry in their daily practice has long been recognized; but it is quite recently that the services of the chemist have been called upon to help solving the many puzzling problems which the foundryman constantly encounters. However, his legitimate place and position is already well established at the larger foundries in the United States and in Europe, besides at such works where a specialty is aimed at (such as car wheels and malleable castings), and the smaller foundries are slowly following their example.

In the hopes of arousing some interest in this important subject also (in this country, and especially) among the members of this association, the following notes and facts are hereby presented as a nucleus for discussion, founded as they are on the best authorities, and in all essential parts having been found correct and a most valuable help to the writer, in connection with his labors and investigations as chemist at different iron and steel works. Even at the risk of appearing pedantic, the writer has aimed at making this treatise as elementary as possible, in order to interest those least familiar with the subject, and must therefore, ask of the well-informed members their kind forbearance.

As we all know, absolutely pure iron does not exist as a commercial product, for what we are working and dealing with is not a single substance, but an alloy, composed of a number of elements in different proportions, the total sum of which, however, seldom exceeds 5 to 10 per cent. Among these elements, carbon is an essential constituent, and one that plays a most important role in determining the physical character of the iron. In fact, its influence on the iron is so great that its presence in smaller or greater amounts is responsible for the three well-known classes—with so distinctly different characteristics—in which iron has been divided, namely, wrought iron, steel and pig-iron: pig-iron containing about 2.5 to 5.0 per cent. of carbon, steel, from .4 to 2.5 per cent., and wrought iron, from about .03 to .35 per cent.; and their characteristics are so familiar to us all that it is here only necessary to recall their different melting points, which for pig iron is from 1,800 deg. F. to 2,200 deg. F., for steel, about 2,650 deg. F., and for wrought iron, about 2,880 deg. F. Again, we must carefully keep in mind that carbon, in pig iron, occurs in two conditions which are distinct in their physical and chemical relations, namely, as graphite and as allotropic modification, combined carbon. If present as graphite (i.e. simply mechanically mixed with the iron), the pig has a gray, soft fracture, but when in chemical union with the iron, the fracture is white and hard, with metallic lustre. In molten pig iron all the carbon is present in its combined form, and it all depends on the time and conditions allowed during cooling, which state—graphitic or combined—it will assume in the casting; the slower the cooling is taking place the better opportunity the carbon will have to crystallize (forming graphite), and the grayer the iron becomes; whereas, if made to cool suddenly (as when poured against a chill block) the carbon is not given this opportunity, and consequently, it is retained, more or less, in its combined state, and the iron becomes hard and white—always provided no other strong agent is present that will break this rule, and of which we will speak presently. The carbon, per se, as long as it remains combined in the pig iron, increases the absolute tensile strength of the iron, but when separating as graphite, it makes the iron weaker, it also increases the hardness, but decreases the elasticity and the melting point of the iron (i.e. white pig iron is somewhat easier to melt than gray). The following analyses of combined and graphitic carbon in a certain coke iron (Embreville, Pa.), will give a clear idea of the influence which the different modifications of carbon exert on the fracture of the pig:

	Per cent.			Per cent.
No. 1 foundry pig.....	3.80	graphite and		.10 C.C.
No. 2 foundry pig.....	3.78	"	"	.25 "
No. 3 foundry pig.....	3.60	"	"	.39 "
Gray forge	3.00	"	"	.70 "
Mottled	1.50	"	"	1.70 "
White	.10	"	"	3.10 "

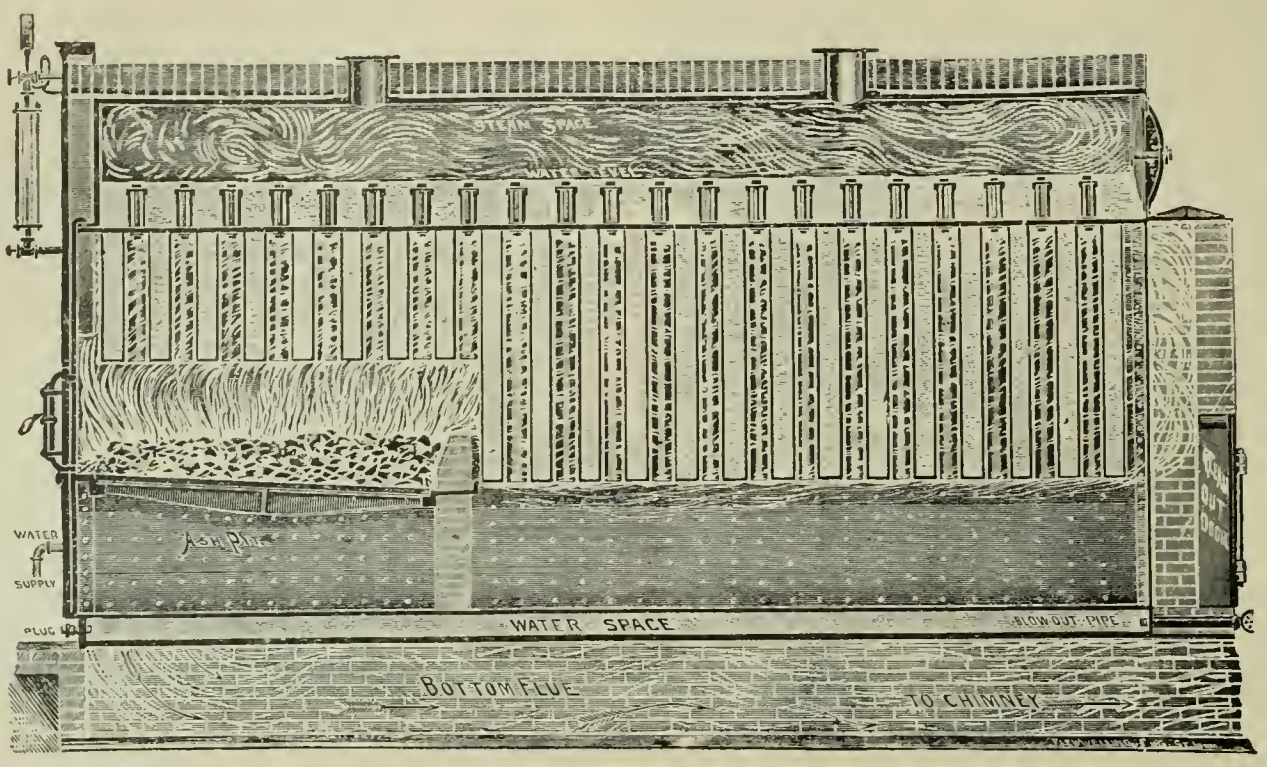
Among the other elements usually present in the pig iron, and the one next to carbon in importance, as regards its effect on the iron, we must place Silicon. Silicon, namely, exerts a controlling influence on the chilling properties of the iron, owing to its tendency of separating the carbon as graphite. Its percentage in the pig iron is generally in proportion to the temperature at which it has been produced. Thus, a coke iron is higher in silicon than a charcoal pig, and varies from a few tenths of one per cent. (as in Swedish charcoal pig), to 1.5 and 2.0 per cent. (in iron usually suited for machine castings), and runs as high as 2.5 to 3.5 per cent. in good soft coke iron; and the "silvery iron" contains about 4 to 5 per cent. silicon alloys with iron in greater proportions than carbon (ferro-silicon contains 30 to 50 per cent. Si.), and decreases the absorption of carbon. Hence, coke iron is generally lower in total carbon than charcoal pig, and iron with 2 per cent. silicon and no manganese has seldom more than 3.8 per cent. C. It increases the fluidity and fusibility of the iron, and lowers its smelting point, makes the iron retain its heat for a longer time, and thus lessens the formation of blow holes, and decreases the shrinkage (in proportion to the amount of graphite that has separated). Added to "pure cast iron" it has been found to improve the strength of the iron up to 2.5 per cent., but above this amount it makes the iron weaker. From the above properties of the silicon it is easy to see why it is that pig iron which contains a high percentage of silicon acts and is used as a "softener," and that by melting various portions of such iron with hard iron, all the different grades can be obtained, from close to very open-grained soft iron. In re-melting pig iron loses about .25 per cent. of silicon, which should not be forgotten. Another disturber of the equilibrium in a pig iron is sulphur. Contrary to silicon, sulphur present prevents the formation of graphite, and consequently, it has a tendency of producing a white, hard casting: it also makes the iron sluggish and full of blow holes, sulphuretted hydrogen gas, causes red shortness, and increases the shrinkage. Besides, being generally irregularly distributed in the iron, sulphur tends to make an uneven, unreliable casting. For these several reasons sulphur has well been called "the foundry man's bane," and owing also to the hindrance it offers to annealing, it should especially be avoided in malleable castings, also in iron intended for car wheels. Sulphur has a great affinity for iron, combining with it at a lower temperature, and in any proportions, up to about 53 per cent., and as its evil effects are perceptible already at a fractional part of one per cent., it must be a matter of great importance for the foundryman to keep track of this element. As a general thing it is rarely found in a soft, open foundry pig—for its presence to any high degree would make the iron more or less close-grained or white—and this great enemy, therefore, is not always shunned as much as it deserves; but its presence in the coke, and sometimes also in the limestone, is certain to bring it in the casting, and thus it happens that a good iron often has been condemned when the fuel and the flux alone were to blame. Good Connelsville coke contains seldom over .6 per cent. sulphur, but at many a foundry 1.0 per cent. S. in the coke is not unusual; and if a basic change and a high temperature be not resorted to in the cupola the iron, in re-melting, will increase .2 to .5 per cent. in sulphur, which is sufficient to spoil it for most purposes, if the silicon be not present in sufficient quantity to neutralize its effect.

To be continued.

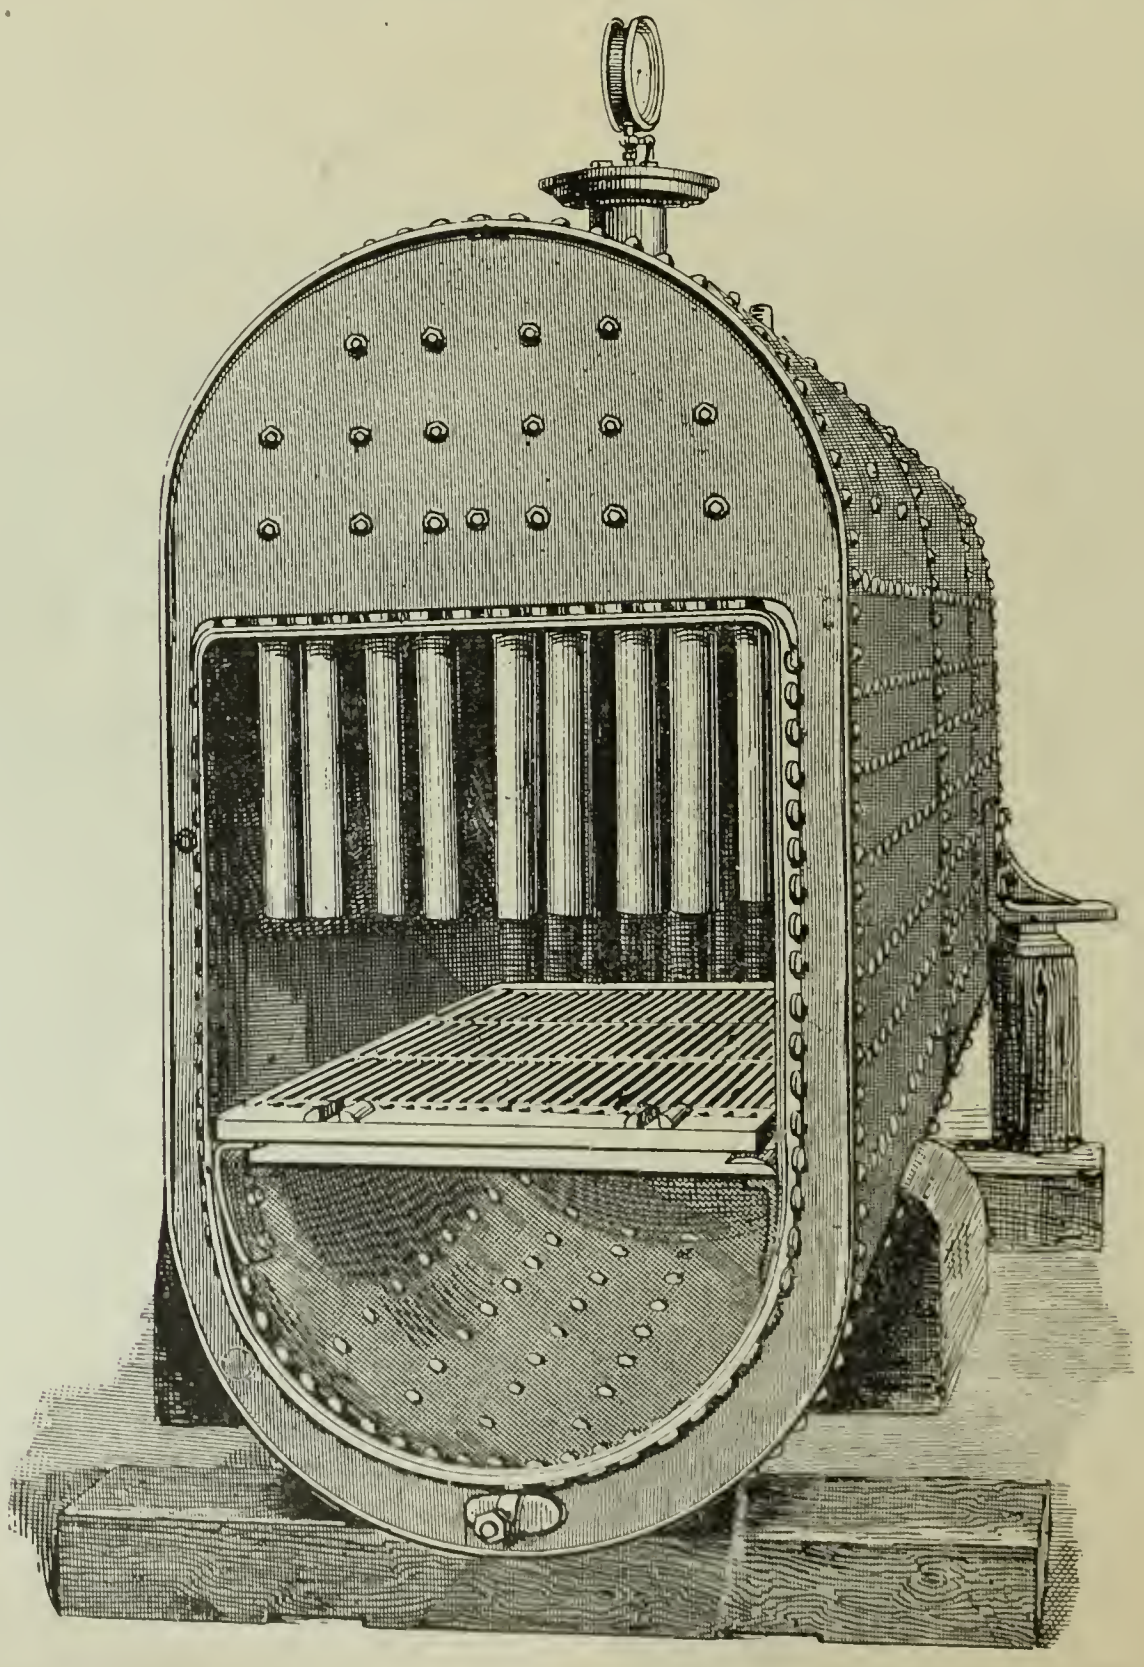
Two or three years ago marl beds were discovered near Orangeville, Ont., and D. B. Brown, T. M. Rowan, R. H. Gillespie, and J. M. Rowan have acquired 500 acres of land in the township of Caledon, within three miles of Orangeville, 400 acres of which contain a bed of marl, varying in depth from eight to twenty-one feet. The marl is pronounced to be particularly good, and suitable for making Portland cement, etc. It will likely be developed at an early date.

KINGSLEY WATER-TUBE BOILERS.

The Kingsley patent water-tube boilers, herewith illustrated, are constructed with two shells—an outer and an inner. The outer shell has vertical parallel sides and semi-circular top and boiler. The crown sheet is horizontal, and extends continuously the entire length of the boiler. It is flanged down three inches along each side for its entire length, and forms the top of the inner shell by being riveted to it along each side. The tubes are threaded at their upper ends with standard pipe



THE KINGSLEY PATENT DROP WATER TUBE BOILER.

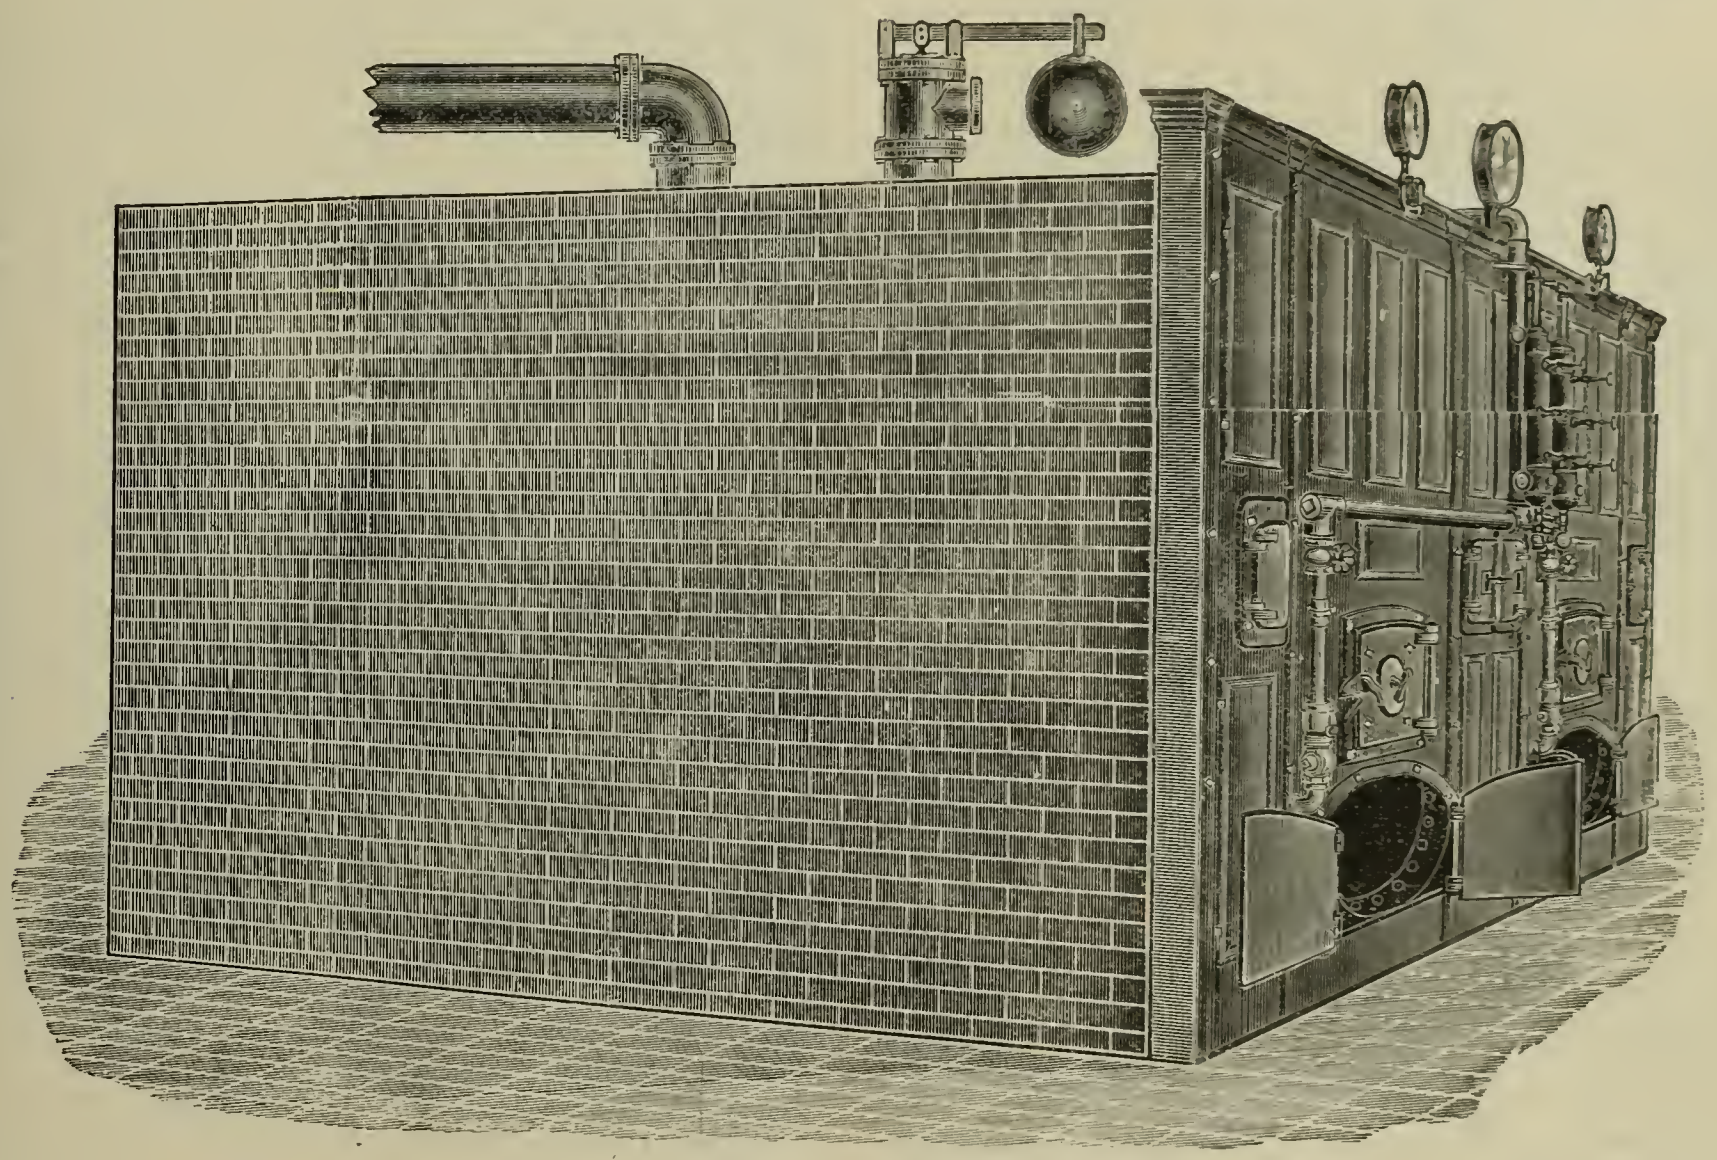


KINGSLEY BOILER—FRONT END VIEW OF NAKED BOILER READY FOR WATER TEST

bottom. The inner shell is fixed parallel to the sides and bottom of the outer shell, by means of two flanged heads and numerous stay-bolts, leaving a uniform space about four inches wide between the two shells extending the full length of the threads, and are screwed into the crown sheet. The bottom ends of the tubes are plugged with ¼-inch iron and are then welded solid. The tubes are made of standard 2-inch iron lap-welded pipe. They are short enough in the fire-box to leave

an ample combustion chamber, and are longer behind the bridge wall. Any tube can be readily screwed in or out of the crown sheet without touching any other tubes. The crown sheet is strongly stayed by stay-bolts, screwed simultaneously at various angles, into the semi-cylindrical top of the outer shell and into the crown sheet. These stay-bolts and those connecting the two shells are headed on each end. The parts of the two flanged heads forming the ends of the steam chamber are likewise stayed by rods screwed simultaneously into each, these rods being headed at each end or fitted with nuts.

The water is contained in the tubes, and in the space between the shells, and extends up a few inches over the crown sheet. As this water surface extends unbroken for the full length and width of the boiler, no rapid fluctuations of water level can take place, although the boiler is a very rapid steamer. It is possible to supply any capacity of water or steam space by extending the outer shell upward above the level of the crown sheet to any desired height. It is sometimes desirable to thus increase the steam space where large volumes of steam



KINGSLEY BOILER—REPRESENTING TWO BOILERS OF 150 H.P. EACH.

are required at one time, which occurs in various industries. No steam drum is used on these boilers. This is a great advantage over most water-tube boilers as well as many other types, as a steam drum elevated far above and away from the hottest fire can of itself act only as a condenser, as it is the tendency of steam to cool and condense immediately on leaving the direct action of the fire. In the Kingsley boiler the tubes, being vertical and short, liberate steam very freely, and without friction or impediment, which in all water-tube boilers with inclined tubes, causes a large percentage of water to be carried up with the steam. This is also one reason why this boiler produces dry steam even under the heaviest forcing. By those who have not investigated, an argument may be advanced regarding the deposit of sediment in the tubes. This, the manufacturers claim, may conclusively be answered by referring to boilers which have been in use for upwards of ten years. One of these in Chicago, being fed on the dirtiest of feed-water, has been in use for nine years. The users, a short time ago, wrote: "We have never had any trouble with the tubes filling with scale or sediment; but, on the contrary, we think they are brighter than new." Hundreds of tubes have been screwed out and examined for sediment, in various parts of boilers which have been running for different periods, and have been found perfectly clean; in fact, any scale formed in manufacturing the tubes appears to be loosened and removed by the ebullition and rapid currents when the boiler is under steam. After such investigations there can be no reasonable doubt on this point.

The reason for this exceptional cleanliness of the tubes is said by the makers to be clear when we consider the construction of the boiler. The feed-water, entering at the front of the boiler, between the shells, below the level of the grate-bars, in passing up becomes intensely heated before reaching the crown-sheet. It is well-known that water heated to a few degrees above the boiling point, parts with most of its impurities, as mud and carbonates of lime, and at a temperature of about 300 degrees Fahr., equal to 52 lbs. steam pressure, it can no longer retain in solution the sulphates of lime, magnesia, etc., which form the much-dreaded scale in boilers. In this boiler, these impurities being separated by the intense heat, precipitate into the space between the shells, at the bottom of the boiler, where the heat is not sufficient to bake them into scale, and whence they can be washed out occasionally through the hand holes. This boiler is, therefore, by its construction, stated to be a perfect feed-water purifier; and no sediment or scale can gather in the drop-tubes, because only purified water reaches the crown-sheet, from which the tubes are supplied.

The boiler, being internally fired, has the fire-box entirely surrounded with a water-jacket. The incandescent gases from the fuel, passing up among the short tubes in the fire-box, are drawn backward among the long tubes to the end of the boiler, whence they divide and return, half on each side, between the outer shell and the brick casing toward the front of the boiler. From this point the now nearly exhausted gases can either be carried by means of a saddle over the front of the boiler direct to the chimney, or they can pass down into a flue under the boiler along to its back end, and thence to the chimney. There is no appreciable difference in economy of evaporation between these two methods of circulation of the gases. The tubes are "staggered" in the crown-sheet and are spaced at such distances that the gases which pass zig-zag and strike each tube at right angles, while being confined on all four sides by the water-jacketed shell of the boiler, lose nearly all their available heat before they are returned on the sides. For this reason this boiler can be operated also as a locomotive boiler. The gases are passed out of the chimney only sufficiently hot to insure a good draft. This boiler requires the same size of chimney as any other type of boiler. For hot-water heating for buildings there is no change in the construction of the boiler, the steam space being simply filled to the top with water. The fuel

economy is the same as for steam purposes. The circulation of the water is the most direct that can be desired, as there is a continual uninterrupted rise from bottom to top of the boiler. For marine purposes there is no change in the essential design of the boiler, the difference being in details and setting, as the brick casing could not be used. It has been installed for the highest pressures, and is as easily cleaned and as durable as any boiler made. The economy of installation is apparent when we note the claim that this boiler occupies one-third less ground area than the other ordinary types of horizontal water-tube boilers, or the return-tubular boilers, and less than one-half their cubic contents. It requires only 6½ feet in height. The brick casing is used only for the return gases, and hence never requires renewing. As there is no firebrick furnace to renew periodically, the repairs are reduced to an absolute minimum. It is not necessary to refer to the exceptionally high evaporative economy of this boiler, as this could be readily predicted from its construction.

THE BARREN LANDS OF CANADA.

On a recent Saturday afternoon J. B. Tyrrell, of the Dominion Geological Survey, Ottawa, lectured to a very large audience in the Biological Department of Toronto University, Toronto, on the timely and interesting theme, "The Possible Resources of the Barren Lands of Canada." Introducing his subject, Mr. Tyrrell said that Canada was just now face to face with problems particularly her own. Reports of the fabulous wealth which reach us from the Yukon and elsewhere in the Dominion are naturally followed by the question: Are our young men being equally well trained for going out to the forest wilds to possess this wealth, as they are for other occupations in life? Continuing, Mr. Tyrrell deprecated the prevailing idea that a trifling knowledge of rocks and minerals is all that is necessary for the equipment mentally of young men going out to the gold and other mineral fields. Ignorance, he said, emphatically, means loss and failure in the locating of mines and minerals. Who would win in such search must be well trained. Only 10 per cent. of the great area of Canada is under cultivation at present; 35 per cent. only is capable of cultivation; there is a vast extent, roughly from about one to two million miles, which will not grow cereals, and which bears little or nothing. There are 750,000 square miles in which there are no fur-bearing animals, and which are rarely if ever visted by white men. These are known to the Indians as the Barren Lands. Of these there are 300,000 square miles in the Arctic Islands, 50,000 square miles in Northwestern Labrador, and 400,000 square miles west of Hudson Bay. Of these the lecturer said that he would consider the latter in his lecture, and try to show that there was every ground for hope that in the not far distant future Canada would have in these barren lands a sub-Arctic mining province, covered with comfortable homes, whose enormous wealth would in a great measure compensate the inhabitants for the rigor of the climate and other privations which are not known where nature is more kindly disposed. The barren lands of Northern Canada are three times as large as the British Isles, are bounded on the north by the Arctic Ocean and on the east by the west coast of Hudson Bay and Fox Channel. They are generally a vast undulating plain, broken by ridges, stony and bare, very flat for the most part, the grassy grounds covering a floor of soft creaceous shales and sandstones: a dreary, rocky, barren country. The highest point is reached in the Stony Mountains, which lie east of the Coppermine River, and are 1,500 feet above the sea level. The lecturer then went on to describe the inhabitants of these lands, who number 2,000 Esquimaux, whose pursuits are hunting and fishing, and 500 Chippewayan Indians, who retire to the forest for the winter. He described the animals, the principal of which is the Arctic caribou. Its flesh is excellent food for explorers and pioneers; it is here in countless numbers, and should it ever become extinct, it could be replaced by the Lapland reindeer. Other animals are the musk ox, which lives in the plains of the north; predatory animals are the white wolf, the wolverine, and the white bear. Whitefish and trout are plentiful in the rivers and lakes, and in the lecturer's expedition to these lands 124 specimens of plants were found. "But," said the lecturer, "it is to the mineral of these lands we must look for any real contribution to the national wealth." He then plunged into a very scientific description of the geology of the country, described the structure and nature of the rocks, showed that from Tobaunt Lake to Baker River there is a great extent of mineral-bearing rocks similar to the gold, silver and copper-bearing rocks on the north shore of Lake Superior, and in the Lake of the Woods district; he said that copper-bearing rocks extend along the Arctic boundary, and that there was every evidence to show that similar conditions existed in the numerous adjacent islands; indeed, there were many thousand square miles of these lands plentiful in copper; so plentiful were the evidences of this mineral that the lecturer thought that the barren lands will be as productive as Michigan. Besides copper and lead, gold, silver and nickel are there, with iron in enormous quantities; in brief, the lecturer had collected abundant evidence to show that there is a great natural wealth in the barren lands of Canada, which can now be reached with little trouble and expense. Ocean steamers can sail to the head of Chesterfield Inlet, which is open three months of the year; south of Chesterfield Inlet are good harbors, from which the Huronian rocks may be explored. Still further south, Fort Churchill is an excellent land-locked harbor, open for five months of the year, from June till November. The Hudson Bay steamer runs from London to the harbor. In every way Mr. Tyrrell thought that these lands were worthy of exploration and settlement; they are easily accessible, and the climate is not too rigorous in winter; and that their vast wealth now locked up will yield splendidly to work and enterprise.

Mr. Tyrrell's lecture was well illustrated by photographs, which were taken during his expeditions to the barren lands. When thrown upon the screen they gave a very good idea of the nature of this country, its inhabitants, animals, lakes and rivers.

MECHANICAL DRAWING TOOLS.*

By S. J. Ireland, Principal of Hamilton Art School.

Many parents have the mistaken idea that by getting a cheap set of drawing tools for a boy as a present they are creating in him an incentive to the study of art. A cheap case of instruments has been the means of spoiling many a boy's ardor for drawing. I have before me two cases of drawing instruments. One of these cases costs but $1.50; the instruments in this case have their points rounded, and their joints can be opened to permit cleaning. For a cheap case this is very good. The other case costs from eight to ten dollars, but as far as the merits of the instruments are concerned, I would rather have the first. Everyone knows what a pair of compasses is and what used for. The cheapest kind have brass cheeks and heads, but it is a well-known fact that brass rubbing on brass causes too much friction. Another kind has double cheeks, and is known as the hair divider. Most compasses are of English make, and these instruments appear to be made to last forever. The instruments made by the Germans, with exception of those made by one firm, are practically useless. But this one firm which is the exception makes the best instruments in the world. The best English compass is known as the Sexton joint. Compared with the German, the English compass is heavy and lob-sided, while the German instrument is finely balanced, easier to handle, and is superior to the English compass in the joint.

Pencil drawings must be inked in. Pens form one of the chief features of the draughtsman's outfit. A pen with both points bent inward should be thrown aside. The screw must not be so near the handle as to leave the ends too long. If overcharged with ink, a pen of this kind is apt to blot. The German pen has short ends and a registered screw. The time saved by the use of this pen is considerable. I have here a pen by the use of which circles and curves can be made without the aid of a ruler. For the finest work a spring point is used. This instrument has not been improved on in the last forty years. The Germans produce a very fine instrument of this kind with which you can take a measurement to the three-hundredth part of an inch. The cost of this instrument is $4.85. The German rotating compass has never been successfully imitated by the English or Americans. An instrument is now made for making dotted lines; it does fine, regular work, and is the means of saving considerable time. For making larger circles a longer radius is required. In the old English beam the pencil point and the point on which the pencil rotates are both of the same length, while the German beam has the advantage of having the pencil point shorter than the other by

*A Paper read before the Hamilton Branch, C.A.S.E.

the thickness of the drawing board. A dotting machine is also made to be used in connection with the beam. Protractors are used when the drawing is so fine as to be measured by degrees, minutes and seconds. All lines drawn on a level surface should be done with the aid of a "T" square. The best kind of these squares are those having an inclined edge. The best set squares are made of hard rubber. The slide rule is of great importance to every class of the community, but very few know how to use it. There is no arithmetical calculation known that cannot be solved by the use of this instrument. More can be done in five minutes with this rule than can be done in five hours or five days by arithmetic and algebra. A book on the use of the slide rule, written by Riddell, may be found in the Public Library in Hamilton.

THE FEDERATED CANADIAN MINING INSTITUTE.

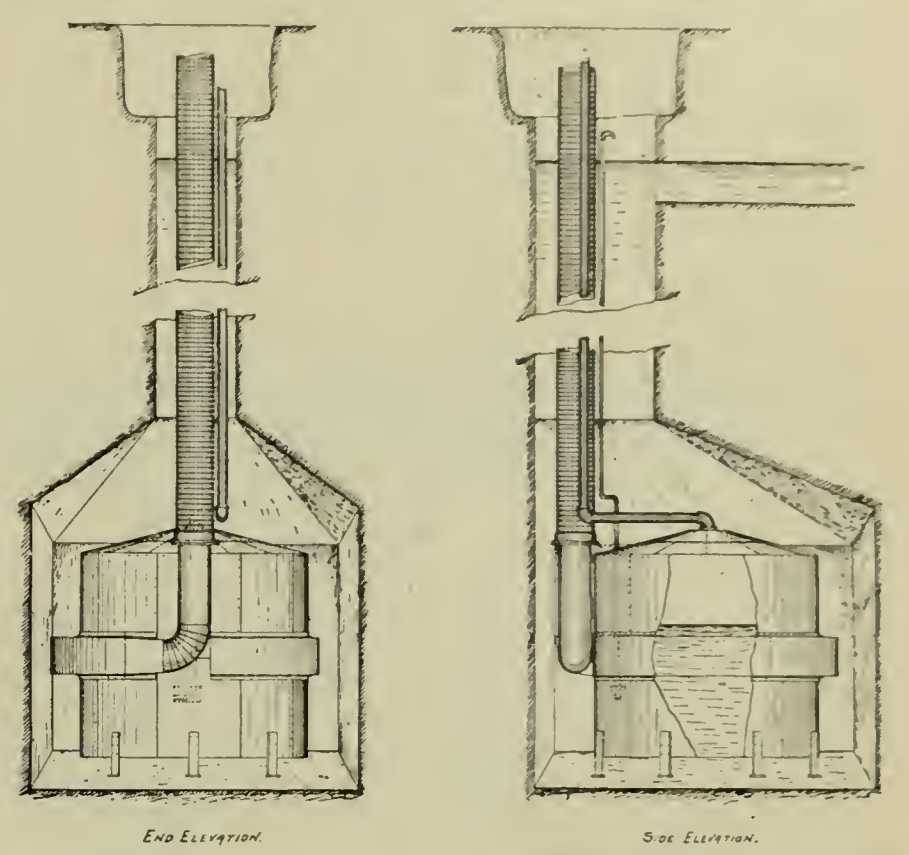
The second conference of the Institute opened in Montreal on March 2nd. As the meeting was held so near our date of publication, we are unable to give a full report of the proceedings. Considerable discussion took place on the effort made by the Canadian Society of Civil Engineers to become members of that association before practising in Canada. The Institute was resolved into the Canadian Institute of Mining and Metallurgy, a constitution being adopted. The Institution passed a resolution condemning the export duty on nickel mat. J. E. Preston, McGill University, read a paper on "Notes on the Ventilation of a Deep Metal Mine as Affected by Seasonal Changes of Temperature," at the evening session. This was followed by "Cableways as Applied to Open Pit Mining," by Spencer Miller, C.E. F. T. Snyder read a paper on "Some Modern Forms of Milling Machinery," and John Birkinbine, Philadelphia, one on "Commercial Progress as Influenced by the Development of the Iron Industry." Hamilton Merritt's paper treated of the gold-bearing reefs and placers of Northern British Columbia, and W. L. Goodwin read some Notes on the Anaylsis of a Rare Mineral. The following officers were elected: President, J. A. Hardman; Vice-presidents, W. A. Carlyle, Victoria; Charles Fergie, M. E. Westville, Nova Scotia; John Blue, and Dr. G. M. Dawson, F.R.S.; members of the council: Nova Scotia, Henry S. Poole, Stellarton; Major L. G. Leckie, Clarence Dimmock, W. L. Libbey, British Columbia; J. P. Hobson, Canal Forks; F. C. Loring, Rossland; W. Blackmore, Coal Creek; and R. G. McConnell, at present of the Geological Survey. Ontario, Archibald Blue, James McArthur, Sudbury; F. T. Snyder, Keewatin; H. Merritt, Toronto. Quebec, G. F. Drummond, G. R. Smith; Penhill, J. Obalski, M.E., Inspector of Mines, Quebec; Treasurer, A. W. Stevenson, Montreal; Secretary, B. T. A. Bell.

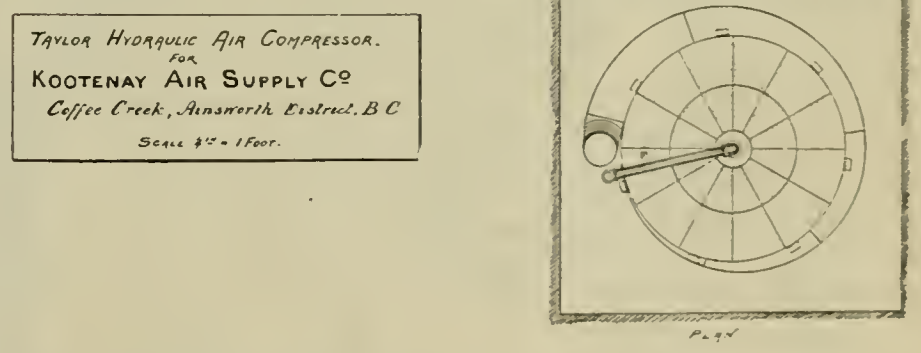
—F. J. Appleby, C.E., and J. J. Wilde have commenced business under the firm name of Appleby & Co., Room 501. Board of Trade Building, Montreal, as manufacturers' agents for bridge work, metals and rubber, mining machinery, tools, etc.

THE KOOTENAI AIR SUPPLY COMPANY.

The compressed air plant under the Taylor Hydraulic Air System, which is now being installed at the camp of Ainsworth, B.C , by the Kootenai Air Supply Co., is of such general interest to the mining world that a detailed sketch of the plant will be of interest to the numerous readers of The Canadian Engineer.

Ainsworth is the oldest working camp in West Kootenai. The ores are silver-lead in a very heavy formation, where the cost of development is quite high, and requires considerable power. The veins carry considerable water, and so far no great depth has been attained on any of the properties. There are several shipping mines in the district, and two concentrators. The point at which the Kootenai Air Supply Co. is installing its plant is on Coffee Creek, about two miles south of the heart of the district. The creek rises 25 miles back from Kootenay Lake in the high altitudes of the Slocan Mountains, and the stream is fed by a huge glacier. Like all mountain streams, the flowage varies abnormally, the lowest reading being about 2,500 cubic feet to a maximum of 8,000 or 10,000 cubic feet per minute. The high water period extends through the summer months, and until late in the fall, or during the period when a greater demand occurs for air. The creek has an average fall of 10 feet in 100, and the company is now building a dam across this creek five feet high, and a circular stave barrel flume, which has been sawed by the Salmo Lumber Co., the staves being 3 inches by 4⅛ inches, bevelled to the shape of a barrel five-eighths-inch round; iron bands, with take-up bolts will be used to hold the flume together, and these will be set every three or four feet on the flume. Joints are broken alternately in the wooden stave, a saw cut being made at the end of each stave, one-eighth inch thick and one inch deep, and a piece of iron of the same size is inserted to join the staves together. The lumber used is cedar, and the flume will be set on ties and wedged in place This form of construction is quite common on the coast, and a flume of the character in question will last longer than a light hydraulic iron flume, the lumber becoming water-soaked and practically imperishable. The total length of the flume is 1,354 feet, and the pressure on the flume will vary from 5 to 10 lbs., dependent on the height of the stream. This flume will cost complete with iron rods, exclusive of grading, about $1.25 per foot. The lumber is laid down dressed at $11.50 per M., lumber being exceedingly cheap in this section, while iron, owing to excessive freight rates, is very high.





The company is proposing to instal the receiving water tank and the down-flow pipe in wood, stave barrel construction being used throughout, so that the only iron in the plant will be the air chamber at the bottom of the shaft, and the ⅝-inch iron rods necessary to hold the flume and the down-flow pipe.

The head under which the plant will operate is 107 feet from the level of the water in the tank to the level of the water in the creek, and the back pressure of the rising water in the shaft will equalize the pressure in the down-flow pipe, so that the severest pressure at any point on the down-flow pipe will not exceed 60 lbs. The hoops will be put on at distances varying from 6 inches to 3 feet. The total depth of the shaft, which is now down about 90 feet, will be 210 feet, of which 20 feet at the base will be for the compression tank. In order to overcome the loss in the Magog plant due to ineffective separation, some slight modifications will be made in the construction of the Ainsworth plant, as will appear from the detail annexed. The down-flow pipe discharges its water into an iron inlet, which extends itself all round the centre or water line of the compression tank, and as the circumference of this tank will be approximately 51 inches, and the water with its corkscrew motion and its high velocity swings around this inlet, every particle of air carried down will be separated, so that the company's engineers figure on an efficiency of at least 70 per cent. of air h.-p. out of the gross h.-p. of the stream.

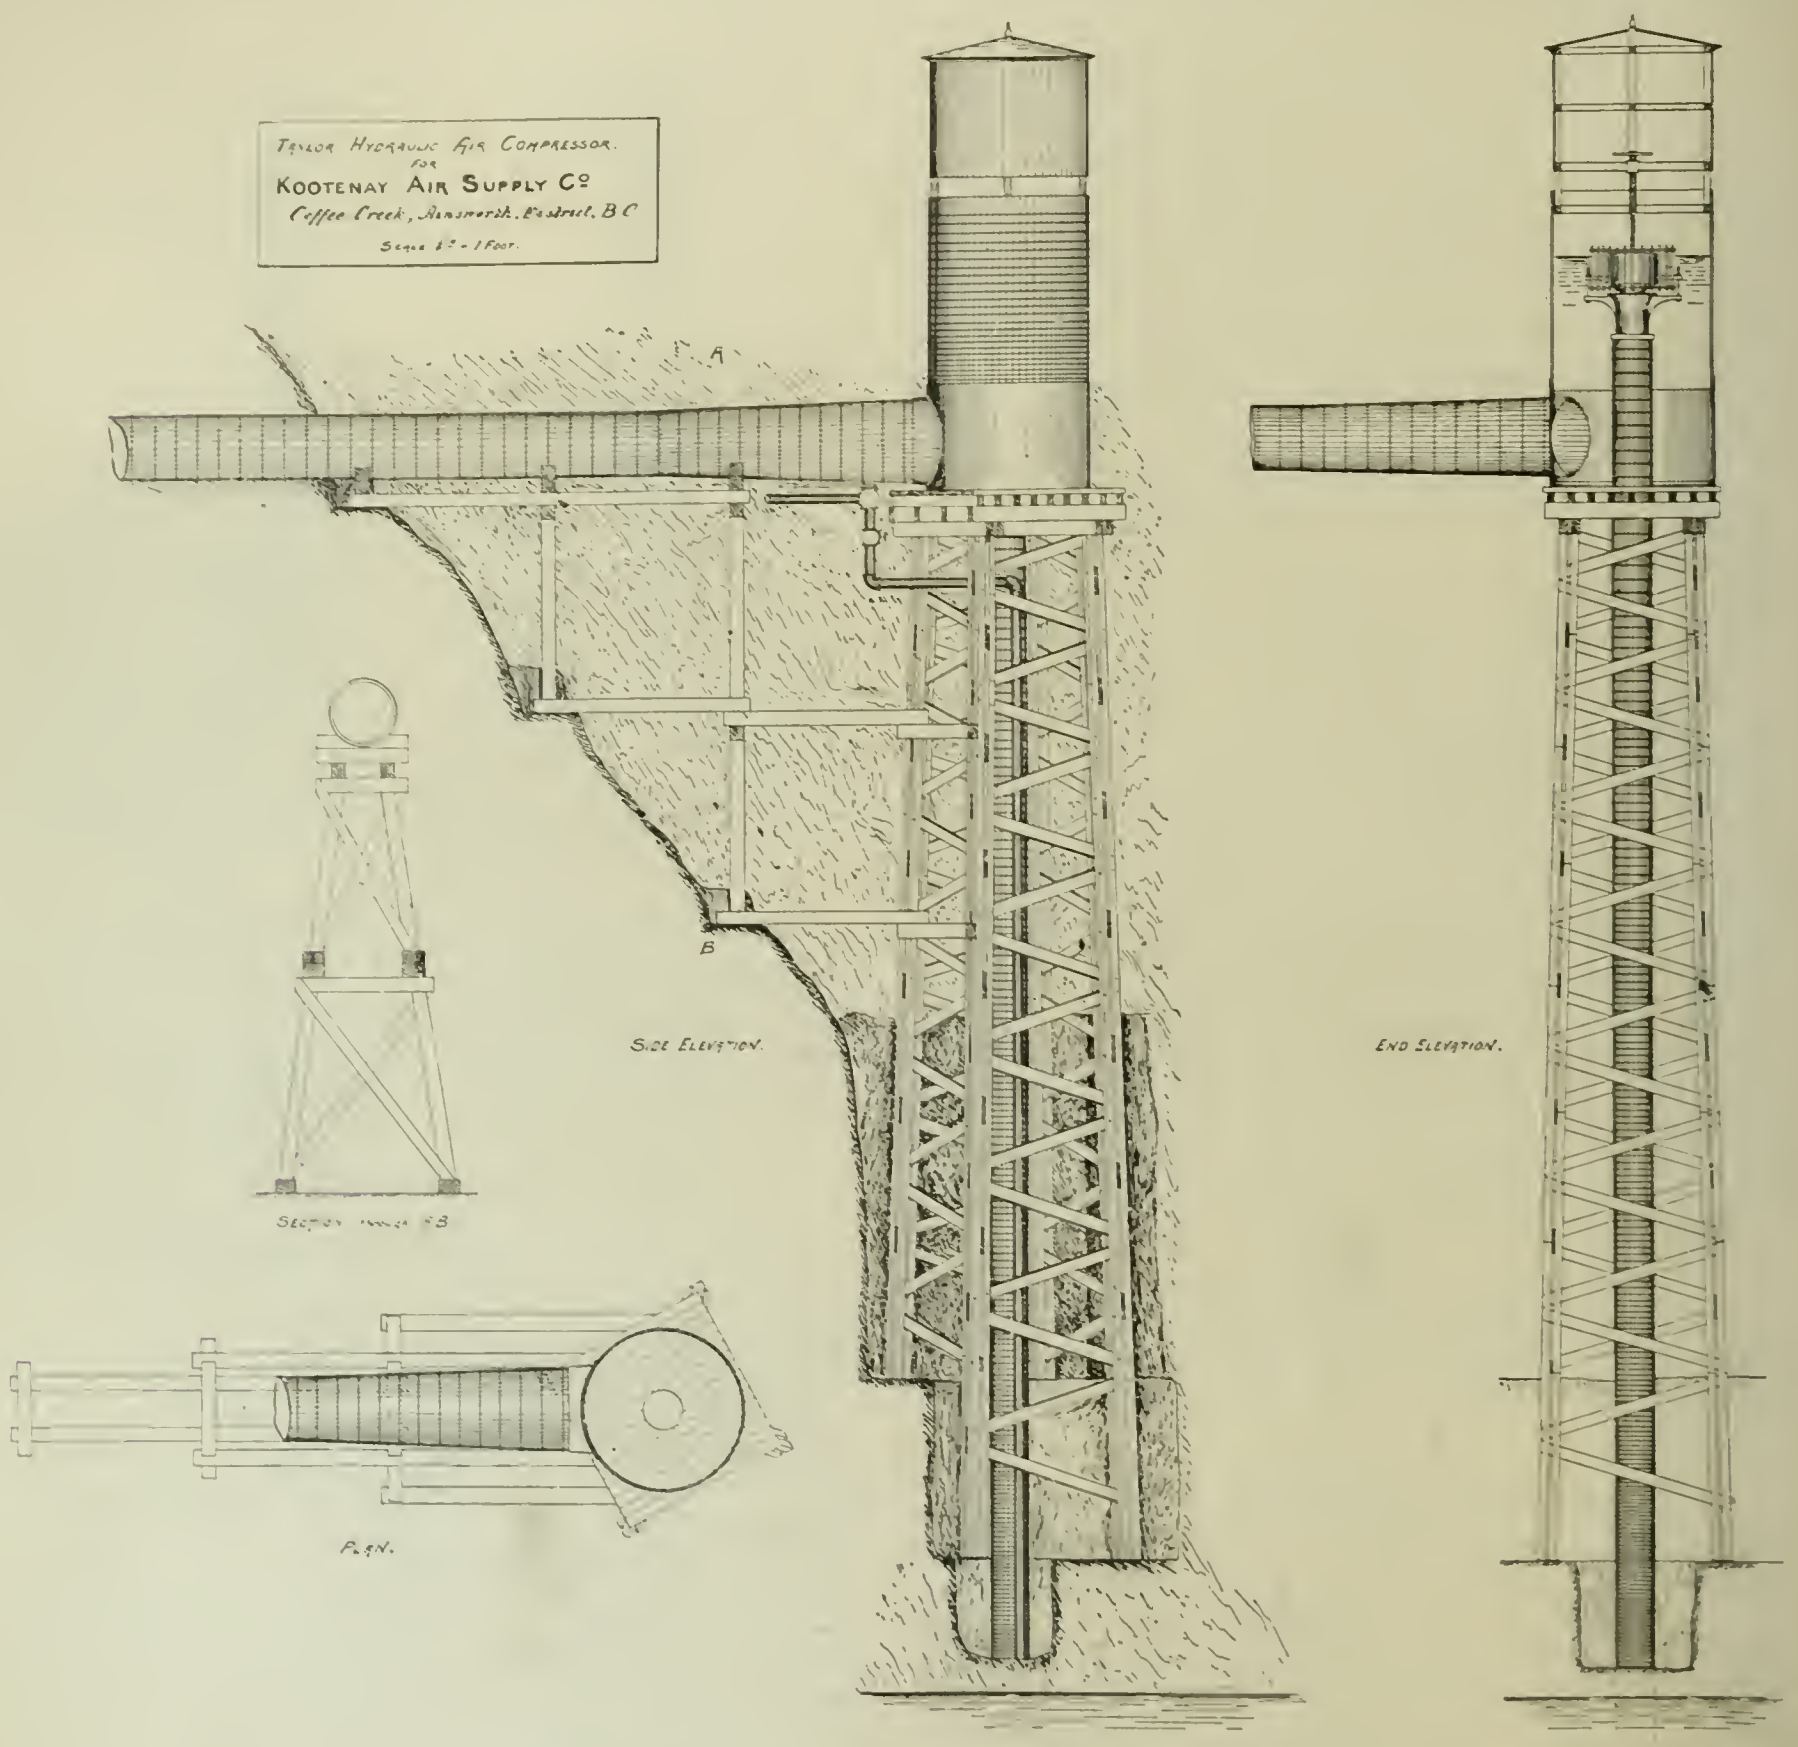
By the substitution of wood for iron in this work, the cost of the installation will be a moderate factor, and when the compressor outputs 500 air h.-p. the h.-p. cost of the air at the compressor site will represent a capital investment of only from $22 to $23. The h.-p. output of the compressor will vary from 340 h.-p., when the flowage is

2,500 c.f. per minute to a maximum of 650 h.-p. when the flowage is 4,500 c.f. per minute, the details of the plant being all worked out for the maximum flowage, which could be maintained throughout the entire year, if necessary, by the construction of further dam accommodation to store the water for the heavy load.

The company is now working 20 men sinking the shaft. The shaft is 6 x 8 feet in area, and a small boiler, 6 x 8 double hoist, and No. 2 Rand drill—all supplied by the Jenckes Machine Company—are now running on the work. The shaft is being sunk alongside the creek, and up to the present time, on account of the hardness of the rock, very little water has been met. Progress at the rate of about a foot per diem in sinking is attained, the cost being between $25 and $30.

Co. expect to sell power for the air drill on the 24-hour run at $3 per day, or less than the price of a miner's wage, and the mine owner will be saved all the capital cost of installing a compressor, with its attendant worry and cost of operation. Any prospector along the line of the pipe-line can tap on with a small pipe, and run a drill or a hoist, the capital cost of which is not very great, and when he is through with his work upon any particular property he can take up his outfit and move it to another claim. The power company, while able and ready to cut existing rates in two, will still make handsome profits, for with a drill rate of $3 (less than half the price of a miner's wage on the 24-hour run) the air h.-p. will still net, if from 20 to 30 drills are connected, between $140 and $150 per h.-p. per annum.

The estimated cost of the pipe lines laid on the ground is $18,000,



The main pipe-line of the company will be run from the compressor to some point on the "Black Diamond" ground, a distance of 10,000 feet. This pipe-line will be 9 inches in diameter in the clear, and with an initial pressure of 90 lbs., and allowing a loss of 10 lbs. in transmission, will discharge 4,600 c.f. of free air per minute, or, with 5 lbs. loss, giving a final gauge pressure of 85 lbs., will discharge 3,000 c.f. of free air per minute. From the "Black Diamond" ground branch pipe-lines will reach out to the principal operating properties in the district, and it is expected that with two miles of these branch pipe lines, varying in size from 3 to 6 inches, from 250 to 350 h.-p. of air can be sold. The pipe-lines will be of wrought iron, with bolted joints and rubber gaskets.

Throughout the Kootenay district the present charge for the air drill, consuming from 80 to 120 c f. of free air per minute, varies from $5 to $7 50 per day, dependent upon the size of the steam compressor plant and the fuel conditions prevailing. The Kootenay Air Supply

a portion of which, however, will be borne by the consumer, bringing the total estimated cost of the plant to $30,000. When once installed, the maintenance and operating expenses should be inappreciable. There is no moving machinery to wear out, no operators needed at the central station, and the life of the pipe-line is almost perpetual, as being laid above ground, it is affected only by atmospheric conditions.

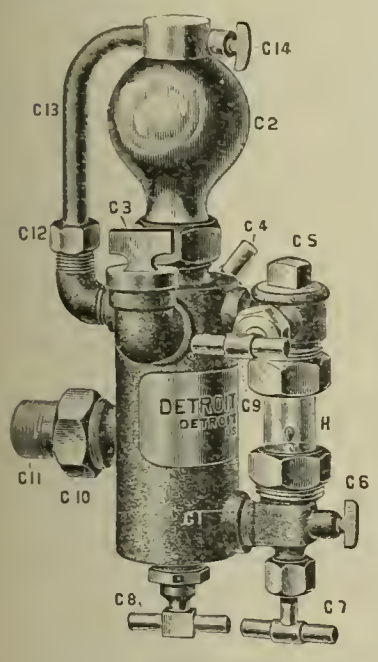
The greatest interest is being taken by miners, who are the largest users of air in the world, in this installation at Ainsworth. It means a vast saving in mining, for there are few mining districts throughout the entire West where a sufficient amount of water power is not available within from five to ten miles of mines to operate plants, and after the capital investment has been made the miner practically gets his motive power (and air is absolutely essential to him as motive power) without any cost other than the interest charge.

Steps are now being taken by the Taylor Air-Compressing Co., which is installing the plant at Ainsworth through its sub-company,

the Kootenay Air Supply Co., to make a similar installation in the Rossland and Ymir districts. In the former district some 750 actual air h.-p. are to-day being consumed, and the total cost of the air h.-p. at the mine to-day averages more than $200 per air h.-p. per annum. This section is one of the most inviting fields for the installation of a plant, the rock being especially hard, and the air power being absolutely indispensable for mining in the district.

A COLD WEATHER LUBRICATOR.

In the Northern States and Canada, where the winters are severe and of considerable length, it is often a difficult matter to maintain a steady feed of oil to the cylinders of engines. This is particularly true in the case of many mills and other steam plants where the engine room is exposed more or less to the cold. The oil thickens into a viscous, jelly-like mass, which will not break up into drops nor feed through the ordinary lubricator. As a result, the valves become cut and worn, and there is a double waste of energy due both to the cold and to the friction. Recently an ingenious lubricator has been designed by the Detroit Lubricator Co., of Detroit, Mich., to overcome these conditions. It is very appropriately called the "Zero," and is shown in the accompanying cut. Right above the support arm, inside the outer shell, is a heating chamber, which is always filled with steam while the engine is working. This steam heats the oil, and keeps it warm and in a liquid state, no matter how cold the weather. Of course, in very cold weather, it will use up some steam to keep the oil heated, just as it does to keep the cylinder heated, but the heat in the one case is just as positive as in the other. This heating chamber is perfectly automatic. In cold weather the steam in this heating chamber condenses more or less, and the condensed water runs back into the steam-pipe, keeping the chamber always filled with steam. These "Zero" cups have been on the market for nearly two years. They have been adopted by almost every American builder of threshing engines and by several Canadian ones. They are also used very generally on stationary engines that have to work in cold locations. Any one interested can obtain a descriptive circular or a complete catalogue showing them by dropping a card to the manufacturers.



ZERO LUBRICATOR.

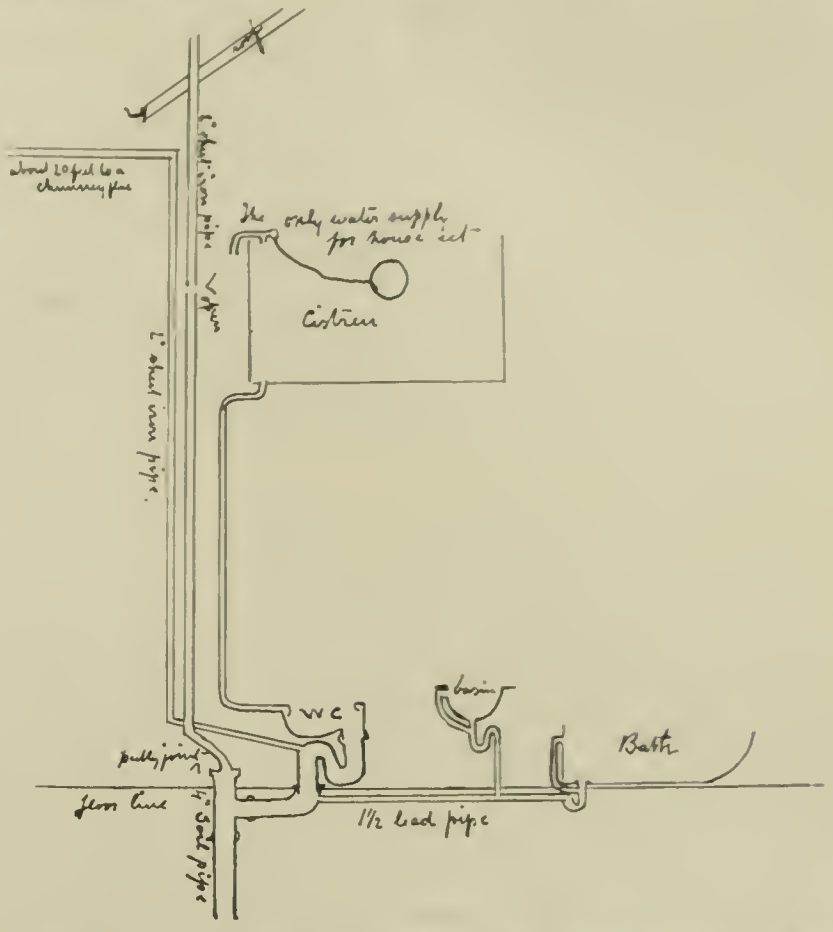
DANGEROUS PLUMBING.

Editor THE CANADIAN ENGINEER.

SIR,—In one of Toronto's large, well-appointed and handsomely furnished residences, a licensed plumber was engaged to remove an old pan water-closet, and the lead bend and P.-trap, and fix in a 4-inch by 4-inch tee in place of the lead quarter bend, and a 4-inch lead bend in place of the P.-trap, and an improved sanitary two-piece water-closet in place of the old pan water-closet.

The house had been fitted up in the first place in the old English style, having a large lead-lined storage cistern, from which the w.c. was flushed, and the range boiler and every water tap in the house was supplied. The cistern itself receiving its water through a ball tap and lead pipe direct from the city water mains. The old pan was vented by the 2-inch horn upward through the roof by a 2-inch sheet-iron pipe that dropped in two when the old closet was removed at the point shown in the sketch between the cistern and a wall having a space of about six inches jammed with about six different lines of pipes.

From the socket of the 4-inch to 4-inch soil pipe tee, the plumber fixed a 2-inch piece of sheet iron pipe up to within 1½ inches of the end of the old pan w.c. vent pipe at the end of cistern (see sketch), and there left it as a completed job, because one end was vertically under the other. By this, most of the sewer gas that should pass out through the roof is abstracted and absorbed by the drinking water stored in the cistern close by, which would partly poison the water and make it unfit to use for domestic purposes. And if not all absorbed by the cistern water, the balance would pass into the room, little if any would pass up the pipe except when the temperature of the room was lower than the outside. From the vent-horn of the new sanitary trap, he took another two-inch sheet iron pipe up and over the ceiling of room for twenty feet perfectly level to a chimney. He could have graded upward to a higher level of 8 feet if he chose. To expect air to circulate through so long and small a pipe laid level is absurd, and if it did deliver the sewer gas in the chimney at the point about 12 feet below the discharge head, it would not ascend upward except when the flue was warm When no fire was burning and the flue was cold the sewer gas would descend the straight flue into the living apartments.



The third error is seen by referring to the sketch at the point where the 1½-inch bath waste joins the heel of 4-inch lead bend. When bath pipes are joined in this way the excrement is liable when it bounces on the heel of bend to rebound back up the 1½-inch pipe, and charge the pipe, beside pressing the foul air in the small pipe through the water seals and by the act of making the water seal to oscillate to break the seal of the trap and leave it open until more water is run in.

This job has only been done within a few weeks time and one would hardly have expected to find such dangerous ignorance displayed, especially in a house where the total cost of good sanitary arrangements and workmanship would probably be only one-tenth of the amount of the house furnishing.

WM. WATSON.

567 King st. W., Toronto, Feb. 15th, 1898.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the metal imports from Great Britain during January, 1896, 1897.

	January. 1896.	January, 1897.
Hardware and cutlery	4,765	1,636
Pig iron	380	504
Bar, etc.	1,236	285
Railroad	..	50
Hoops, sheets, etc.	1,840	827
Galvanized sheets	654	2,031
Tin plates	22,508	11,929
Cast, wrought, etc., iron	1,684	1,874
Old (for remanufacture)	191	..
Steel	2,586	4,521
Lead	519	978
Tin, unwrought	3,046	422
Cement	468	518

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

KINGSTON NO. 10.

A special meeting of Kingston No. 10 Canadian Association of Stationary Engineers was held in Congress Hall, January 26th, 1898. It was called for the purpose of visiting the members of Parliament, B. M. Britton for the city and David Rogers for the county, *re* legislation. The following members of the association were present: President Simmons, Vice-President Asselstine, Past President Donnelly, Bros. Hoppins, Blomely, Woodrow, Davis, Taudrein, Linton, Strong, Gascoyne, Selley, Derig, Bajus, Turnbull, sr., Tait and Orr. There were also present certificated members of the Ontario Association: David Leslie, P. McArdle, James Ross and George Hazlett, of the Winnipeg branch of the association. All of the above members formed a deputation and proceeded to B. M. Britton's office; when David Rogers arrived the business was proceeded with, President Simmons reading and presenting an address, along with a copy of the Act, to Mr. Britton, after which H. Hoppins, in a few well chosen remarks, pre-

sented a copy of the address and the Act to David Rogers. Both gentlemen replied. After a few questions were asked regarding the working of the association, which were answered satisfactorily by President Simmons, Past President Donnelly, Bros. Hoppins and Blomely, the question was put to Mr. Britton if he would support the bill. He stated he would, and more than that, if the party having the bill in charge wanted any help to get it in shape to go before the House, he would only be too happy to give him any help he could to make it a success. Mr. Rogers was then asked if he could support it. He said he could not see anything in the bill but what was right and just, but he would not pledge himself until he made further enquiries. The deputation retired, feeling satisfied that when it came before the House he would support it. At a regular meeting held on the 3rd February, there was a resolution made that a hearty vote of thanks be tendered to B. M. Britton and David Rogers for the reception they gave the deputation of engineers who waited on them, and also that a copy of the minutes of the special meeting be sent to THE CANADIAN ENGINEER for publication.

JOHN L. ORR, Sec.,
Kingston No. 10, C.A.S.E.

C.A.S.E., TORONTO, NO. 1.

C.A.S.E., Toronto, No. 1 held its regular meeting on Feb. 2nd. There was a good attendance and two initiations, and two propositions were received. There were several questions in the question box. Bro. Miln took them up and figured them out on an old door, the new blackboard not being finished. Bro. Miln also took up the question, "What Makes a Motor Go?" and his explanation was highly appreciated by all the brethren present.

Their regular meeting on Feb. 16th, was held in their hall, 61 Victoria Street. There was a fair attendance, and after the regular business was over, and the question box opened, it was found to be full of Scranton School questions, some of which were answered and some taken home by the brethren, to ponder over till the next meeting night, when they will be expected to work them out on the new blackboard.

At the regular second Tuesday evening open meeting, Feb. 15th, Bro. Wickens continued his talk on The Steam Engine Indicator, after which a hearty vote of thanks was tendered to Bro. Wickens.

At the regular meeting on March 2nd, Engineers' Hall, 61 Victoria street, there was a good attendance and one candidate was initiated. A number of questions were asked and figured on the blackboard by Bros. Past Presidents Fox, Moseley and Bannan, which work was greatly appreciated by the brethren present. A Legislative Committee reported that all the members of the Dominion Government present in Toronto had been written to, asking their support for the Engineers' License Law and Boiler Inspectors' Act, which is to come up at the present session, and a number of them have promised their consent.

The regular open meeting will be held Tuesday evening, 8th inst. Mr. St. John has kindly consented to give a talk on the strength of boilers. The president expects a large attendance, and invites all engineers to the open meeting. The members "do not want to keep all the good things to themselves."

—The annual meeting of the Canadian Press Association will be held in Ottawa, 10th and 11th inst. Among the important matters to be considered will be the postage question, insolvency legislation, and the visit of British journalists to Canada. Frank A. Munsey, who has been without doubt the most successful modern publisher, will deliver an address on and discuss the "Elements of Success in Newspaper Publishing." It is hoped that one or two of the following representatives of the British Institute of Journalists will be present: Lord Glenesk (London *Morning Post*), Sir Hugh G. Reid, M.P., J. M. Maclean, M.P., and Sir Edward Russell. The dinner will take place as usual, when a number of important speeches will be made.

—P. B. OWENS writes to a contemporary:—"In these days of enormous productions of iron and of stupendous commercial transactions, it no doubt will interest many of the present generation to learn that mining, smelting and manufacturing of iron was an established industry in the County of Essex, Ontario (then Upper Canada), in the early part of this century. A smelting furnace was built in the Township of Gosfield, on the farm of Michael Fox, about one mile north of where the Olinda post-office now stands. The ore was taken from natural deposits in the adjoining Township of Mersey, and the fuel used was charcoal produced in the immediate vicinity. The writer remembers how wonderful the furnace, the smoking stacks of wood covered with earth, and the sluice boxes for the washing of the ore all appeared to his childish mind. A large quantity of timber was consumed in the production of the charcoal, timber which, if now standing, would be of enormous value. But no kind of timber, except white oak, was then considered of any value, even black walnut being made into fence rails, and much of it actually burned up in clearing the land."

—The German Association for Acetylene and Calcium Carbide will hold an exhibition of the recent progress that has been made in this industry, and at the same time a congress to consider the various scientific and practical questions that have arisen in connection with it. The exhibition, which will be held in Berlin from March 6th to March 20th, will comprise acetylene generators, lamps, purifiers and mixing apparatus, acetylene burners, motors and soldering tools, calcium carbides, electric furnaces and electrodes, and the different varieties of machinery used in the manufacture of the calcium carbide. Rigorous regulations have been adopted by the Berlin police to prevent any premature explosions, and no generating apparatus using more than about one-half pound of the calcium carbide will be permitted in the main exhibition hall. The use of pure, compressed, or liquefied acetylene gas will be prohibited, and a limit of a hundred and twenty pounds pressure has been placed on mixtures of the gas. The use of acetylene gas for illumination is increasing, and the coming exhibition will show how general its application can be made, as well as the simplicity with which the gas is generated.

Industrial Notes.

THE St. Thomas, Ont., city council is looking for plans for the new city hall.

GEO. GRANT, Arnprior, Ont., has the contract for building a bridge at Burnstown, Ont.

CHAS. RITZ has bought the foundry until lately run by C. Ritz & Co.—*New Hamburg Independent.*

THE Grand Trunk Railway, it is stated, contemplate building a mammoth hotel in Quebec city.

D. RICHARDS & Co. speak of the erection of a steel and brick addition, 90 x 40 ft., to their soap factory at Woodstock, Ont.

A BY-LAW, under which Goderich, Ont., is taking $50,000 stock in the Elevator Company, has been carried by 416 majority.

J. WILSON, foundryman, St. Catharines, Ont., has received a large order for wire cables for mining in British Columbia.

THE Stellarton, N.S., Lubricating Company, we understand, intends shortly to commence the manufacture of their lubricant on a large scale.

J. R. ADAMSON, Cornwall, Ont., is one of the incorporators of the Black River Creamery Co., Limited, which intends building a factory at once. Capital, $2,000.

APPLICATION has been made for the incorporation of a company to be known as the Woodstock, N.B., Sash Balance and Lock Company, to manufacture and sell a patented window raising and locking contrivance.

THE residents of North Cypress, Man., are endeavoring to make arrangement for a bonus of $10,000 to a flour mill and elevator. The mill is to have a capacity of 300 barrels and the elevator 100,000 bushels capacity.

THE new agricultural hall at Shawville, Que., will cost about $3,000. The design has been made by architect Edey of Ottawa, and is for a building of octagonal shape, the dimensions being 99 feet diameter, and a 27-foot wall.

THE Knowles Bicycle Company, Limited., is applying for incorporation; chief place of business, Brantford, Ont.; capital, $50,000. The provisional directors are: W. J. Knowles, W. G. Nott, J. T. Ham, J. H. Ham, and Maria Knowles, Brantford.

A DOMINION charter has been granted to C. Guimond, Beauharnois, Que.; C. F. Lalonde, Montreal; J. Leduc, Beauharnois; J. B. Roy, Beauharnois; Delia Rochette, wife of Emilien A. Manny, Beauharnois, as the Star Iron Company, Limited, with a capital of $60,000.

FRED. H. DOUGHTY, formerly in the employ of Jas. McPherson & Co., Hamilton, Ont., has purchased the business of H. B. Livingston & Son, machinery agents, Leicester, Eng., and, with Mr. Livingston, jun., will continue the business under the firm name of Livingston & Doughty.

A PLEASANT event took place at the B. Greening Wire Company's works, Hamilton, Ont, on a recent evening, when the employees of the rope department presented the foreman, Charles A. Herald, with a set of drawing instruments. Louis Beck made the presentation, with a felicitous speech. Mr. Herald made a suitable reply, thanking his co-workers for the pleasant surprise.

W. BURROW, C. Stewart, J. Milne, J. Stewart and C. Milne, Hamilton, Ont., and W. Burrow, jr., Chicago, Ill., are applying for a Dominion charter as the Burrow, Stewart & Milne Company, Limited, to manufacture stoves, furnaces, scales and hardware generally. Chief place of business Hamilton, Ont.; capital, $250,000.

LONDON, Ont., wants an engine to run its stone crusher.

ST. CHARLES COLLEGE, Sherbrooke, Que., is to have a new building.

A ONE hundred thousand dollar block of buildings is to be erected at Victoria, B.C., by the Molsons Bank.

DESERONTO will vote on a $20,000 bonus towards a charcoal iron smelting works in that town, to cost $250,000.

PETER STEWART, Arnprior, Ont., has secured a position with the Wm. Hamilton Manufacturing Co., Peterboro, Ont.

THE contract for building the Simcoe county, Ont., House of Refuge has been awarded to A. Tessier, Penetanguishene, for $14,966.

THE New Brunswick Government has invited tenders for the extension of the breakwater at Centreville, N.B., estimated to cost $4,000.

THE Carleton Place, Ont., council has had a letter from the Perth Waterworks Co., Limited, asking for a similar franchise from that town as they received from Perth, Ont.

THE Lancaster Machine Works, Lancaster, Ont., are kept busy with orders in all lines, especially in their line of cotton mill machinery, in which they are building up a good trade.

A NEW single span iron bridge will be placed over the River Raisin, at South Lancaster, Ont., the coming spring, to replace the old wooden structure, which has been condemned.

THE London, Ont., Foundry Company has received orders for four carloads of wheelbarrows, forges and miners' tools, for shipment to the Klondyke. The order comes from a Vancouver firm.

THERE is every indication of a good dairy season during 1898, and manufacturers are preparing for it; already the Lancaster Machine Works have booked several orders for their patented specialties.

THE Nelson, (B.C.), Iron Works are employing 12 men at present. They make and repair machinery for the mines in the vicinity. They recently completed a contract for water hydrants for Grand Forks.

WE have received from the International Correspondence School, Scranton, Pa., a booklet containing some hundred testimonials from pupils all over the world, who have studied under its direction with much benefit.

THE Massalon Paving Brick Company, of Massalon, Ohio, is endeavoring to place its wares on the Canadian market. The Massalon brick is larger than any of Canadian manufacture, and is said to be one of the best made.

G. H. MCGILLIVRAY, township clerk, will receive tenders up to noon on the 19th inst. for the construction of two stone abutments on the site of the Lancaster bridge, South Lancaster. Tenders will also be received for concrete abutments.

THE stock and plant of the Beaver File Works, Levis, Que., was sold by auction a short time ago. The purchasers were Marcau & Jauteau, who have now decided to change the name, and in future the concern will be known as the Mechanics' Star File Manufacturing Co.

THE Moore & White Co., of Philadelphia, manufacturers of clutch pulleys, couplings, etc., have appointed the Lancaster Machine Works, of Lancaster, Ont., as their representatives in Canada, from whom all particulars regarding these justly celebrated friction driving devices may be obtained.

THE Hamilton, Ont., municipal estimates for 1898 contain the following large items, among others: Catharine street sewer, $22,000; Wood street (John to James) sewer, $3,700; trunk sewer, east end annex, $20,000; Aberdeen avenue sewer (Locke and Garthe) $3,900; disposal works, expense, $10,000; gully drains and ventilators, $2,500; Mountain drain improvements, $2,500.

THE Ingersoll-Sergeant Drill Company has issued a very neat booklet, which is practically a condensed edition of their catalogue of air compressors, It contains illustrations of the various types of compressors, and shows some of the uses they may be put to. Copies of this handy little volume may be had by applying by postal card to the Montreal office, 299 St. James street.

G. W. RICHARDSON, representing the proposed Rossland, B.C., Gas Company, asks the following concessions from the municipality: The right to construct and operate gas works and to supply gas to the citizens of Rossland for ten years, with the right to lay mains and service pipes along the streets of the city; gas to be of a standard not less than 16-candle power, and to be supplied at a rate not more than $2.50 per thousand feet; work to commence in six months and to be completed within two years; gas to be supplied to the city at $3 per month per light, if 25 lights are taken, and $2.50 per lamp if more than 30 lamps are used; corporation to have the privilege of purchasing the plant at any time within ten years at a price to be decided by arbitration.

J. HANBURY, Brandon, Man., is negotiating with the municipality to start a wood-working factory. The proposed building is to cost $20,000.

W. PERRY, representing the R. H. Buchanan Co., engineers, Montreal, in connection with the Rider Ericsson Hot Air Pumping Engine Company, recently, at their works, Walden, N.Y., made a test of the new improvements on the hot air pumping engines, which far exceeded any previous tests, and was in all details satisfactory The severest tests were applied.

THE Willson Carbide Works, Merritton, Ont., have been so crowded with orders that they decided to start their works on Sunday; that is, instead of closing at 12 o'clock Saturday night and remaining closed until 12 o'clock Sunday night, they now run until 7 o'clock on Sunday morning, and remain closed until 5 o'clock Sunday afternoon. To these arrangements the Lord's Day Alliance took exception, and caused fourteen of the employees to be summoned before the police magistrate.

THE Hamilton, Ont., papers reported that Engineer Barrow had made a test, for capacity, of the pumps and machinery at the sewage disposal works. The showing made was 3,175,000 gallons in 24 hours, which is 175,000 gallons above the requirements. This work was done with one engine only in operation. Mr. Barrow expects to be able to bring about a great saving in chemicals, not only by a change in the precipitants used, but also through the large settling surface. At the east end works the machinery which runs the pumps is now being used to operate the mixers, and thus a saving in fuel is effected. Mr. Barrow expects, in time, to bring the cost of operation to a much smaller figure than at present. From the number of changes proposed it would appear that plant is at present found to be expensive.

A BRIDGE has recently been completed at Dundas, Ont., that is a decided departure from the usual class of work done by municipal councils. To protect the banks from the cutting action of freshet water, caused by the curving of the current at this point, the abutment walls were made just high enough to provide a margin for highest freshet known, and on the tops of these walls steel rail piers were placed to support the superstructure, and the abutment walls carried up and down stream in such a way as to turn the current, making in all a length of wall of about 200 feet. The walls were topped with a cap having a half-round face, with 4-inch projection and 12 inches depth. All of this work is of concrete construction. John S. Fielding was the designer and contracting engineer; J. F. Armour, the town engineer, in charge.

H. J. BEEMER, president of the Pontiac and Pacific Junction and the Ottawa and Gatineau Railways, stated recently that preparations for beginning active operations on the new bridge that is to be built across the Ottawa from the city of Hull at Nepean Point were well under way. The contract for the substructure has been given to a New York firm, while the superstructure will be built by the Dominion Bridge Company. There will be five piers, with a cantilever span of 550 feet in the clear, with arms of 250 feet each. The total length of the superstructure, according to the plans, is to be about 1,300 feet. The bridge will carry a railway track, two tracks for electric cars and a sixteen feet roadway on each side. The object of the 550 cantilever span is to get the piers out of the great accumulation of sawdust in the Ottawa river. The total cost is estimated at about $750,000.

THE following are some of the orders lately received by the Goldie & McCulloch Co., Limited, Galt, Ont. J. R. McComb, flour mill and oatmeal mill, including engine, etc.; Jas. Pender & Co., St. John, N.B., "Ideal" engine; Michigan Central Railway Co, two locomotive boilers; Montreal Transportation Co., Kingston, "Ideal" engine; Delhi Fruit Co, Delhi, one heater; C. G. Gelinas & Co., Three Rivers, "Wheelock" engine; Jas. Richardson & Co., Kingston, "Wheelock" engine, boiler, condenser, shafting, etc.; Maritime Sulphite Fibre Co., Chatham, N.B., heater; Orangeville Electric Light Co., Orangeville, one boiler; Cronkhite Bros., Wisawasa, engine, boiler, heater, etc.; J. S. Metcalf & Co., Chicago, elevator at Coteau Landing, "Wheelock" engine, condenser, feed pump, two boilers and one "Ideal" engine; G. M. Angier & Co., Boston, for Asylum at Fairville, N.B., two "Ideal" engines, two boilers, heater, feed pump, etc.; N. Wenger & Bros., Ayton, one "Ideal" engine; Ogilvie Milling Co., Winnipeg, Man., two boilers; Dominion Bank, large bankers' safe; Electrical Power and Manufacturing Co., Hamilton, engine, boiler, etc.; Molson's Bank, Montreal, two bankers' safes; D. Marshall & Co., Aylmer, two boilers, heater, etc.; Wm. Hamilton Manufacturing Co., Peterboro, six boilers; M. Beatty & Sons, Welland, one boiler; the T. Eaton Co., Toronto, two "Ideal" engines; S. Lennard & Sons, Dundas, one "Wheelock" engine; Bank of Hochelaga, Sherbrooke, large bankers' safe; Bank of Hamilton, Hamilton, large bankers' safe.

A THEATRE to cost $30,000 will be built in St. Roch's, Que.

THE Granby, Que., rubber factory is being extended. Neil & Kent have the contract at $8,500.

THE Welland Vale Bicycle Co., St. Catharines, Ont., have shipped recently 50 wheels to Austria.

ARTHUR DENISON, Toronto, architect, has passed the Walkerton town hall, and taken it off the contractors' hands.

A CONTRACT for building a bridge over the Holland River near Bradford, Ont., will be let during the coming summer.

RIDGETOWN, Ont., has offered a large bonus and exemption to W. E. Hall, furniture manufacturer, Galt, Ont., to remove to that town.

THE Ontario Rolling Mills, Hamilton, Ont., lost no time in getting their premises into shape after the fire, and will soon have everything in as good condition as formerly.

RHODES, CURRY & Co., Amherst, N.S., recently obtained a contract to build 50 twenty-ton box cars for use on the extension of the Drummond Counties Railway at Montreal.

WORK at the Shawenegan Falls, above Three Rivers, Que., is to start shortly, and the hotel there has been reopened for the accommodation of tourists and people connected with the works.

DARTMOUTH, N.S., has a proposition before it to bonus a pulp mill to have a capacity of 20 tons per day. The promoters have secured options on suitable water power and land in the town.

THE Taylor Air Compressor Company, of Montreal, is installing a 500 h.p. plant at Ainsworth, B.C., and expects to distribute the power to mines within a radius of five miles. A full description of this plant will be found on another page.

THE Almonte, Ont., town council has been approached by the Perth Waterworks Co., asking if the council would be willing to enter into negotiations, even in an informal way, with the ultimate view of granting them a franchise for the supply of water and light.

THE Three Rivers, Que., Iron Works is completing the erection of a large brick machine shop and foundry, in connection with their already extensive works. The firm has large contracts on hand, which will give full work to their establishment for the next few months.

AT a recent meeting of the Essex County, Ont., Council the Road and Bridge Committee sanctioned the construction of the following: New bridge over River Canard, cost $1,732; new bridge over Bell River, cost $1,099; new bridge over Tremblay Creek, on county line between Essex and Kent.

IN April, 1897, the Cooper Machine Company of Toronto was incorporated, with $20,000 capital, one-fourth of which was paid. Last month the creditors had a meeting, and their statement showed assets of $4,800, against liabilities of $5,500. An offer of 40 per cent. was made and accepted.

THE local papers in Almonte, Ont., are discussing a system of water works for that town. The finances of the town are in good condition, and such a scheme might be put through; however, the laying down of the mains would be a most expensive undertaking, as almost every foot of excavation would be rock cutting.

JOHN MCCONNELL, of McConnell's Electric Carriage Works, Guelph, Ont., has invented a carriage wheel which ought to prove a revelation in carriage manufacture. The new wheel is set on roller bearings and has no boxings to break or get loose. It is dustproof, and requires oiling once in a season, there being no friction to require the continuous use of oil.—*Guelph Herald.*

THERE was a meeting of the Iron Founders' Association of Montreal recently, in the reading room of the Laurie Engine Company. Among those present were: W. H. Laurie, H. R. Ives, J. H. Garth, Thos. Monaghan, Wm. Rodden, John Laurie, E. Lamb and G. H. Weaver. During the evening a most interesting paper on "The Chemistry of Iron" was read by Ernst A. Sjostedt.

THE board of management of the public works of St. John, N.B., will receive tenders till April 1st for the supplying of about 3,116 tons of best quality 24 and 12 inch cast-iron water pipe, according to specifications and drawings prepared by Wm. Murdoch, Esq., C.E., engineer and superintendent S. and W. Supply, copies of which specification may be had on application to the director, A. Chapman Smith.

IN our last issue, THE CANADIAN ENGINEER stated that a writ had been issued against the Welland council of 1897 by the Waterous Engine Works Company, claiming damages for the non-fulfilment of a contract to purchase a fire engine. The statement, we find, is incorrect. A local informant states that our item might truthfully refer, however, to the village of Fort Erie, which is having some trouble with the Waterous Company.

THE secretary of the General Hospital, at Kingston, Ont., has been instructed to advertise for tenders for the reconstruction of the Watkins' wing, the cost of which is estimated at $12,000. The plans provide for twenty rooms. The question of putting in an elevator has not yet been decided.

THE Somerville course of lectures for 1898 at the Natural History Society Hall, Montreal, has been announced. The following lectures will interest our readers: Thursday, March 24th—The Modern Steamship, by Prof. A. J. Durley, B.Sc., Assistant Professor of Mechanical Engineering, McGill College. Thursday, March 31st—Precious Metals: Where they come from and how they occur, by Prof. F. D. Adams, M.A.Sc., Ph.D., president of the Natural History Society. Thursday, April 7th—Coal and Iron, by Osmond E. LeRoy, B.A., of McGill College. Thursday, April 14th—Our Railways, by Prof. Cecil B. Smith, M.A.E., Assistant Professor in Civil Engineering, McGill College.

IN the works of the Robb Engineering Co., Amherst, N.S., has a concern of world-wide reputation. At present, in every department, the hum of industry is heard, not only during the day, but night. Recently there was a test of a Robb-Armstrong engine. This one, which is compound, goes to Europe to be placed in an electric installation, and will be completed and ready for shipment at an early date. It is 125-h.p. Besides this one just referred to, three compound engines of the same type, each 200-h.p., being made for a foreign order, two of 225-h.p. each, for the Rathbun Co., Deseronto, Ont., and two more of 150-h.p., each, simple, for St. Thomas, Ont. These engines are of the side-crank type. In another part of the premises a large boiler is being finished, which will go to Parrsboro, N.S. It is known as the Mumford improved patent boiler. It is entirely cased in, with furnace in centre, and the smoke returns round the outer part of the shell. The boiler is arranged so that the water has a positive circulation, and the steam is collected in a large horizontal dome at the top. The whole arrangement is such that a great saving in fuel is claimed to be effected.

THE new steel swing bridge across the Lachine Canal at Seigneurs street, Montreal, for which tenders have been called, is to replace the present old structure, which is too light in construction to allow of an electric car service. It has only a clear roadway of seventeen feet, and a total width of twenty-eight feet. The new structure will have a clear roadway of thirty-seven feet, with two sidewalks of four and a half feet in width, and a clear roadway of twenty-six feet. Its length will be one hundred and thirty-eight feet between ballast walls, and be about eighteen inches higher than the present structure. The Atwater avenue bridge across the Lachine Canal is expected to cost about $75,000. The bridge is to be a swing bridge, with a clear span between abutments, ballast wall of two hundred and forty-three feet. The total width of the bridge will be thirty-eight feet, giving five-foot sidewalks on each side. The bridge can be built during the season of navigation, the abutments being placed far enough from the canal bank, so as not to interfere with the canal walls. The centre pier is founded on concrete placed within a square made of piles, with rods passing through the walling pieces. The rest pier work down the centre of canal, is composed of cribs, with ten-foot openings, and will be about two hundred and ninety feet in length.

RECENTLY a number of the people of Sarnia, Ont,, witnessed at the Doherty Stove Works a test of T. Doherty's latest improvement in iron casting—the transforming of cast iron directly into steel by an air blast, passed through the melted metal as it emerges from the cupola. For some time Mr. Doherty has been at work on a new method for decarbonizing iron in the process of casting and bringing the resultant metal to a higher grade of steel than was obtainable by his original process. The basis of the latter was the introduction of a steam jet to the cupola. The new process is based upon the use of compressed air. A specially designed cupola also forms part of the new process, we are informed by a local contemporary. The metal, as melted, drops in a small stream through the bottom of the receptacle to a receiver below, and as it falls through a powerful blast of air is directed against it, which blows out the impurities, which find escape through an opening in the back of the cupola. The effect of the introduction of air under pressure is marvellous. The carbon, sulphur and silicon in the iron can be eliminated to any extent desired by the foundryman by regulating the pressure, with the result of producing a steel casting suitable for the class of work for which it is required. At the test described the blast was regulated for stove plate casting and did not show the highest results obtainable, but it clearly demonstrated the superior character of the process over that of the original patent. Metal produced under the air blast process shows all the characteristics of steel under the hammer, the drill or the lathe, and there appears to be no doubt that Mr. Doherty has solved the problem of producing steel from ordinary pig iron at a single process, at once simple and cheap.

J. E. Lusby intends starting a feed mill at Amherst, N.S., in a short time, and has ordered a 40-horse power boiler and engine from the Robb Engineering Co.

Senator Poirier, Shediac, N.B., has ordered a 60-horse power engine and boiler from the Robb Engineering Co., Amherst, N.S., for running a flour mill and shingle mill.

An application has been made for a charter under the name of the Nickel Steel Company of Canada, the incorporators being: John McLaren of Brockville, manufacturer; George B. Douglas, of New York, manufacturer; Alexander Fraser, of Ottawa, lumberman; David McLaren, of Ottawa, lumberman; F. F. Vandervoort, of Pittsburg, manufacturer; George A. Cox, of Toronto, capitalist; Nathaniel Dyment, of Barrie, lumberman; Alexander McLaren, of Buckingham, lumberman; Andrew Trew Wood, M.P., of Hamilton, merchant; John Moodie, of Hamilton, capitalist, and John Patterson, of Hamilton, secretary. The company wants power to "explore for, develop, operate and acquire by purchase, lease or otherwise, gold, silver, copper, nickel, lead, iron, coal and other mines and properties, and to dispose of the same by sale, lease or otherwise; to manufacture and treat metals, minerals and ores, and to carry on the business of manufacturing therefrom and in combination with other metals, minerals, ores, substances and minerals and all articles of merchandise that may be manufactured therefrom." It also wants power to construct railways to reach or connect the mines, etc., and to establish steamship lines. John Patterson, Hamilton, the promoter, says there is $20,000,000 of capital behind the enterprise.

Electric Flashes.

The Guelph Light and Power Company recently started up its new Brush arc machine.

The Cardinal, Ont., Electric Light Company, Limited, has been incorporated; capital, $20,000.

The Buckingham Reduction Co. of Buckingham, Que., is installing a 200 K.W. power generator. The order was given to the Royal Electric Co.

The Richmond County Electric Co. has purchased a 60 K.W. "S.K.C." two-phase generator from the Royal Electric Co.

The Toronto Railway Company has just placed an order with the Canadian General Electric Company for 20-G.E. 1,000 motors with K-10 controllers.

S. Lennard & Sons, of Dundas, placed an order some time ago with the Canadian General Electric Company for a 100-light incandescent plant.

The Ossekeag Stamping Company, Hampton, N.B., has purchased a 200-light incandescent plant for lighting the works from the Royal Electric Co.

The Sherbrooke, Que., Street Railway Company has recently placed an order with the Canadian. General Electric Company for additional G.E. 1,000 equipments.

The British Columbia Railways Company has placed an order for a freight car, using "Brill" trucks and G.E. 1,200 motors, with the Canadian General Electric Company.

The Electric Light Co., Edmonton, N.W.T., has purchased a new plant complete, including a 75 K.W. "S.K.C." two-phase generator, with "Stanley" transformers, from the Royal Electric Co.

The Midland Electric Light Co., Midland, Ont., recently placed an increase order with the Canadian General Electric Co. for a 60-kilowatt, single-phase alternator of the company's standard type.

The Metropolitan Street Railway Company, Toronto, has placed an order with the Canadian General Electric Company for G.E. 1,000 equipments to replace the motors burned in the fire recently at the car barn.

W. B. Davey will immediately commence work for the lighting of Grand Forks, B.C. The order for the electrical machinery complete, including a 1,500 light alternator, has been given to the Royal Electric Company.

The Chateauguay and Northern Railway Co., Montreal, has placed an order with the Canadian General Electric Company for a 325-kilowatt steel frame generator. This will give that road a total capacity of 525 kilowatts.

The Hull, Que., Electric Company has ordered thirty-six G.E. 1,000 motors from the Canadian General Electric Company. These will be used as four-motor equipments, making in all fifty-two motors of this type which the Hull electric road will have in operation.

The Canadian General Electric Company is supplying three small direct connected units for the C.P.R. steamships on the Stikine River. These machines will be 4 kilowatts each, direct connected to vertical engine of special type, running at 600 revolutions per minute

The Canadian General Electric Company has been awarded the contract for supplying electrical machinery for lighting and power purposes at Ashcroft, B.C. The three-phase system will be used, and the pumping for the town waterworks will be done by an induction motor.

The Canadian General Electric Company has closed a contract with the Montreal Transportation Company at Kingston, Ont., for a 25-kilowatt generator of the well-known direct connected type. This machine will be used for lighting the new elevators and other buildings of the company at Kingston.

There is a good deal of favorable criticism of the kindly action of the Royal Electric Company in coming to the assistance of the Lachine Rapids Company, the power-house of which was burnt on the 6th ult. The Royal Electric Co. lighted Westmount and Mile End for its competitor.

The council of Orillia, Ont., has instructed Wm. Kennedy, jr., hydraulic engineer, Montreal, to visit the Ragged Rapids and give an estimate of the probable cost of the hydraulic work, with information as to the best methods, etc. The Canadian General Electric Co. and the Royal Electric Co. have been asked to estimate on the proposed municipal lighting and power plant.

The Canadian General Electric Company has been awarded the contract for supplying the entire electrical equipment for the new St. Thomas Street Railway. The order covers two 100 kilowatt generators, and eight two-motor equipments. The order for cars was given to the Ottawa Car Company, and for steam engine to the Robb-Armstrong Engineering Company, Amherst, N.S.

The Auburn Power Co. at Peterboro, Ont., has ordered a direct connected sub-station unit from the Canadian General Electric Company, consisting of a 75 horse-power induction motor. From this outfit current will be supplied at 500 volts to small power users throughout the town of Peterboro, it having been found that the high price of induction motors prevented their general use.

The Electric Reduction Company, of Buckingham, P.Q., have placed an order with the Canadian General Electric Company for a 1,000 horse-power three-phase revolving field generator to be used for electrolytic work. The machine will be similar to those installed at Lachine and West Kootenay, except that the current will be supplied at the low potential of 75 volts.

The Canadian General Electric Company has closed a contract with the E. B. Eddy Co., Hull, Que., for a 500 and 350-light multipolar direct current generator, for lighting its mills at Hull. With these machines will be installed standard marble panels containing instruments of the latest type. The contract also covers the supply of material for the wiring of the place in strict accordance with the latest standard requirements of the fire underwriters.

The Sydney Electric Light and Gas Company, of Sydney, C.B., is making extensive alterations and additions to the plant, and has placed an order with the Royal Electric Co. for one 60 K.W. and one 40 K.W. "S.K.C." two-phase alternator, these machines being connected to deliver 150 volts per phase. This is the fourth order that has been placed with the Royal Electric Co. for low tension generators of this type within the last few months, and is an evidence of the growing popularity of these machines.

The Toronto Railway Company recently placed an order with the Canadian General Electric Co for an 850-kilowatt direct connected, direct current generator, which has since been installed and is now in operation in the power house. This machine is practically identical with one of the same type and size supplied by the Canadian General Electric Company to the Toronto Railway three years ago. The new machine is being installed to take the place of a direct connected unit, of another make, which had to be discarded.

The T. & H. Electric Co., successors to Kay Electrical Manufacturing Co., reports the following recent sales in Hamilton, Ont. Norton Manufacturing Co., 15-h.p motor; Bain & Colville, 20 light dynamo; Max Bernstein, 1-h.p. motor; Leitch & Turnbull, 10-h.p. and three 15-h.p. direct-connected elevator motors and attachments; Bain & Sache, one 1-h.p. motor and 12 light dynamo; Electric Light and Power Co., several motors; G. H. Meakins, Esq., one 1-h.p. motor; Ontario Plating Works, one 400 gal. plater; Domestic Specialty Co., one 5-h.p. motor; D. Moore & Co., Limited, one 150 gal. plater; Tolton & McKay, one 1-h.p. motor; City Brass Foundry, one 5-h.p. motor; Hand & Teale, one 1-h.p. motor; Post Office, one ½-h.p. motor; Geo. D. Membery, one 3-h.p. motor.

A BY-LAW for the establishment of an electric light system for Beeton, Ont., was voted on and carried by a unanimous vote a short time ago.

THE Welland, Ont., Aqueduct and Power Company has been organized, with a capital of $25,000, to supply electricity for light, heat and power.

THE Acadia Coal Company's charter, Stellarton, N.S., has been amended so as to permit the company erecting an electrical plant and all necessary requirements for electric lighting.

THE British American Light and Power Company is seeking incorporation to build electric tramways and operate systems for electric lighting in the Yukon district, Northwest Territories and Northern British Columbia.

CHIEF ENGINEER HOBSON, of the Grand Trunk Railway, and a representative of the General Electric Co., spent a day a short time ago looking over the tunnel, with a view to introducing electricity to supersede steam as a motive power.

THE Royal Electric Co. has presented its friends with a very handsome desk convenience, which consists of a very large and well-bound blotting pad, with a calendar and indexed engagements book in the margin. The whole souvenir is one of the most beautiful and serviceable articles it has been our pleasure to receive in a long time.

BY Ontario letters patent, the Saugeen Electric Light and Power Company of Ontario, Limited, has been incorporated. Charles Edward Kilmer, of Southampton, electrician; Clarence Hurd Burnham, of Port Elgin, electrician; Joseph Barber and James Barber, of Georgetown; Edward Kilmer, merchant, of Walkerton, are the parties. Capital, $20,000.

MARKHAM, Ont., has settled its claim against the Waterloo Mutual Fire Insurance Company, caused by the burning of the waterworks and electric light station on the 16th ult. The loss claimed by the corporation was $1,593, on which $1,550 was allowed by the company's inspector. The council started at once to rebuild. The new boiler and engine room will be made fireproof.

IN a recently published interview, B. S. Jenkins, superintendent of the Canadian Pacific Railway Company's telegraph, said that a heavy copper wire is to be strung from Montreal to the Pacific coast, the work to begin almost immediately. The new cable to be laid between Vancouver and Victoria left England on one of the company's new steamers recently purchased for the Yukon Territory trade.

THE first regular meeting of the Royal Electric Engineering Society was held in Montreal not long ago. The following were elected officers for the present session: Hon. president, Wm. H. Browne, general manager Royal Electric Company; president, Wm. Bucke; vice-president, W. S. Dix; corresponding secretary, R. F. Morkill; recording secretary, W. G. Angus; treasurer, L. A. Howland; librarian and curator, F. Cushing; committee, J. Burnett, L. Mudge, K. B. Thornton. This society has been formed by the members of the engineering staff of the Royal Electric Company, and has as its primary object the advancement of knowledge in engineering subjects.

THE Toronto Electric Motor Co., Toronto, and Thompson Electric Co., Hamilton, have amalgamated, the change in the firm to take effect on the 15th inst., under the name of "Toronto Electric Motor Co., Limited." The Hamilton factory will be moved to Toronto, and will occupy the new buildings which the company is to finish by the first of May. The new shops will be of the most modern type, with traveling cranes, etc. With this change the new company will be in a position to do the heaviest work in power apparatus, also arc and incandescent work of every kind. All communications should be addressed to Toronto Electric Motor Co., Limited, 107 Adelaide St. West, Toronto, Ont.

D. A. STARR, president and manager of the Cornwall, Ont., Electric Railway Co., appeared recently before the council of Peterborough, Ont., and explained a scheme for the construction of an electric road from there to Chemong and Lakefield, and connecting in town with the Jackson and Nicholls park, and south to the locks. Mr. Starr said his company also proposed to place four steamers on the back lakes, one steamer to run to Stony Lake, two on the Lakefield-Chemong round trip, one leaving each place each morning, and the fourth running from Chemong to Bobcaygeon. The electric road, Mr. Starr explained, would handle freight, and give a half hour service between Peterborough and Lakefield and Chemong. The company propose to lease both the Chemong and Lakefield lines from G.T.R., convert them into electric line and take over its freight business. The former road would be diverted so as to enter the park. The cost was roughly estimated at $350,000, and the company asked the town to guarantee the interest for twenty years on $150,000 of bonds at 5 per cent.

THE new 2,000 light dynamo purchased by St. John's, Que., in January, to replace the present machine, has been installed.

WE are indebted to the Packard Electric Co., St. Catharines, Ont., for their neat monthly memorandum books and blotter calendars.

THE city of Three Rivers, Que., and the North Shore Power Company are negotiating for the running of the waterworks by electricity.

CHAS. MACBETH, son of Col. Macbeth, London, Ont., has been appointed engineer-in-charge of the construction of the St. Thomas street railway.

THE town council of Napanee, Ont., has accepted a proposition made by J. R. Scott, agreeing to install an incandescent and arc plant within one year.

AN accident to the generating plant of the Electric Power Co., at Montmorency, left the twenty thousand incandescent lamps in Quebec City in darkness, on Sunday, 27th February.

ENGINEER LEYDEN, of the Cataract Power Company, has submitted to E. G. Barrow, city engineer, Hamilton, Ont., a proposition for running the sewage disposal works by electrical power.

THE Halifax and Bedford Electric Company is seeking incorporation to build an electric railway from Halifax to Bedford, with such extensions as may be approved of by the municipalities. The head office of the company will be in Halifax, and the capital stock is placed at $250,000.

IT is stated that the Montreal Street Railway Co. will leave its present power house to the Royal Electric Co., and that it will be kept in reserve in case of accident, when the new arrangements are put in operation by which the street railway will be run by power from Chambly.

THE British-American Light and Power Company are applying to the Dominion Parliament for power to construct and to operate by electricity and other power, tramways at Dawson City, Fort Selkirk, and points in the Yukon and North British Columbia; and to operate heating and lighting systems.

APPLICATION is being made for incorporation of the North Shore Electric Railway Company, with powers to construct a railway on the north shore of the St. Lawrence, starting from a point near Three Rivers and through the district of Three Rivers and other districts. Also to generate and sell electrical energy.

AT the next session of the Legislature a Winnipeg company will ask for a charter to build an electric railway from that city to St. Andrew's Rapids, and through the municipalities of Springfield, St. Boniface, Kildonan, St. Paul's and St. Andrew's. The company also propose to construct saw mills, boats, telegraph and telephone lines.

SHAREHOLDERS of the Hamilton Radial Electric Railway met Feb. 22nd to consider matters the outcome of the relinquishment of the Leather interest in the road. The business was not in shape for immediate consideration, however, and the meeting was adjourned for two weeks. With the retirement of Thos. E. Leather from the company it is probable that the original idea of continuing the railway through Burlington and on to Bronte will be dropped, at least for this year.

JNO. PATTERSON, engineer of the Cataract Power Co., Hamilton, is also interested in promoting the new company which is being formed to manufacture steel and nickel, and electric power will be used. The water will be taken from the Chippewa Creek and the power canal will be enlarged to double its capacity. The power houses will be at Reynoldsville, Ont. Mr. Patterson states that power will be generated by his company by May 1, although it will be months before the works are completed. Poles are now being distributed along the G.T.R., and power will be conveyed to Hamilton, Ont., along that route.

AT the annual meeting of the Toronto Electric Light Company, the financial statement presented showed a surplus of $7,000 over dividends paid. A steady growth is shown in the business all through the past year, especially in private incandescent lighting and power. The old board of directors were re-elected, as follows: H. M. Pellatt, president; W. D. Matthews, vice-president; S. F. McKinnon, Hugh Blain, W. T. Murray, Hon. Geo. A. Cox, Robert Jaffray, W. R. Brock, A. E. Ames, Samuel Trees, Thomas Walmsley, H. P. Dwight, Frederic Nicholls, Hugh Ryan. J. J. Wright, general manager; W. A. Martin, secretary.

THE annual meeting of the Bell Telephone Company was held in Montreal, February 23rd. The net revenue for 1897 was $297,751.57, and after dividends have been deducted the company will carry forward $82,364.17 to its 1898 account. There were present at the meeting: C. F. Sise, president; R. Mackay, F. X. St. Charles, G. A. Greene, P. R. Gault, Hugh Paton, C. R. Hosimer, R. Archer, R. W. Shepherd, Chas. Cassils, T. D. Hood, F. G. Payne, R. P. McLea, C.

A. Briggs, C. F. Paul, James Wilson, Herbert Wallace, George Sumner, H. A. Budden, M. S. Foley, E. Rawlings, John Crawford, J. A. Grenier, George H. Holt, D. Ross Ross, Charles Garth, F. B. McNamee, James Shearer, James Williamson. The annual report was submitted as follows: "Nine hundred and eighty-three subscribers have been added during the year, the total number of sets of instruments now earning rental being 30,445. The company now owns and operates 349 exchanges and 261 agencies. Thirty-five miles of pole and 703 miles of wire have been added to the long distance system in 1897; of these five pole miles and 200 wire miles are in the Ontario department, and 30 pole miles and 494 wire miles are in the Eastern department The long distance lines now owned and operated by the company comprise 16,567 miles of wire on 6,095 miles of poles. Under the authority of the shareholders $66 500 bonds have been sold during the year, the premium thereon being 10 per cent. Continuing the policy adopted in past years, your directors have charged to contingent fund $150,000, that amount having been expended during the year on construction rendered necessary by the introduction of trolley and other strong wires, but which has not increased the earning power of the plant. The following directors were elected: C. F. Sise, Robt. Mackay, John E. Hudson, Robert Archer, Wm. R. Driver, Hugh Paton, Charles Cassils, Thos. Sherwin.

Railway and Marine News.

THE story is revived that the C.P.R. will erect a million bushel elevator at St. John, N.B.

IT is proposed to run one of the Conneaut car ferries to Port Burwell, Ont. this season, instead of both to Port Dover.

GEORGE F. BAIRD, Yarmouth, N.S., has purchased the steamer "City of Monticello," for a price in the vicinity of $20,000

A DEPUTATION from Lancaster, Ont, has requested the Dominion Government to make an appropriation of $10,000 for a wharf there.

THE Sault Ste. Marie *Star* says the steamer "Cambria" will be thoroughly rebuilt and again take her place on the Windsor-Soo route.

THE Alberta Railway Company have sold to Mackenzie & Mann, for use on the short line to Lake Teslin, a quantity of steel rails and four locomotives.

A SYNDICATE has been formed to operate two steamers on the Kingston and Wolfe Island ferry, and Kingston and Gananeque route, the coming season.

THE contract for building the Cobourg, Northumberland and Pacific Railway, running north from Cobourg, Ont., to the C.P.R., has been signed by C. H. Bowen.

IT is stated on good authority that the present intention of the company which controls the M. & N.W. Railway is to extend the line to Prince Albert this year.

THE Grand Trunk Railway authorities are putting new colonist cars on their Winnipeg route that for comfort and appearance excel anything of the sort yet seen in this country.

REPRESENTATIVES of D. C. Corbin have succeeded in obtaining the endorsation of the council of the Rossland Board of Trade for a railway charter from Cascade City to Grand Forks.

THE Grand Trunk Railway system has received for service in its western traffic ten locomotives of the heaviest and most powerful build, from the Baldwin Locomotive Company, at Philadelphia.

THE contract for building the Midland Railway line from Windsor to Truro, N.S., 60 miles, has been let to Fitzpatrick Bros., New Glasgow. The road will be graded and ironed by next fall, it is said.

THE C.P.R. shops are busy turning out new passenger coaches and locomotives to meet the demand for new rolling stock created by the boom in business and the extension of its service in the West.

THE second compound locomotive ordered by the Canadian Government Railway System from the Baldwin Locomotive Works, Philadelphia, has been shipped to Montreal, where it will be put together.

THE Canadian Pacific Railway has sent a representative to Newfoundland to engage 1,500 laborers to proceed to British Columbia to work on the Crow's Nest Pass Ry. The wages offered are $1.50 a day.

THE Government has decided to send immediately the chief engineer of the Department of Public Works, Louis Coste, and the chief engineer of the Department of Marine, Lt.-Col. Anderson, to the Stikine River and over the Canadian route to Dawson city, for the purpose of seeing what improvements are necessary to overcome obstructions to navigation. It is also the intention to erect a wharf at Dawson after inspection.

THE new pier at Margaretville, N S, is completed, and the cost, $10,854, slightly more than the tender of the contractors, Simmons & Burpee, Gibson, N.B. The work has been done to the entire satisfaction of the Dominion Government engineer, C. E. W. Dodwell. As Margaretville is the nearest approach to a natural harbor on the Nova Scotia shore, between Minas Channel and Digby Gut, the necessity of a safe breakwater has been admitted.

THE Newfoundland cabinet has concluded an arrangement with R. G. Reid, the contractor who built the Transinsular Railway, to operate the entire railway system of this colony, six hundred miles, for fifty years, in return for a land subsidy of 2,500 acres per mile. Mr. Reid will pay over to the Government one million dollars guarantee. This money, with the interest accumulations for fifty years, will belong to the colony at the expiration of that period, the railway then reverting to the representatives of Mr. Reid.

DAVIS Dry Dock Company is very busy this spring filling orders for launches, etc. There are being built a passenger and freight steamboat for Homer & Co., of Gravenhurst, Ont.; 25-foot steam launch for Muskoka Lake; three boats for the Adirondacks, for New York owners; one 17-foot ¾ h.p. gasoline motor; one 20-foot long gasoline motor, one 36-foot long steam engine, beside one 34 feet long and another 50 feet long on the stocks. They are getting out plans for a 20-foot boat with a small steam motor to fit back in the stern, a very pretty little launch, with plenty of room and at a very small cost.

THE steamer "Tecumseth," owned by McArthur Bros, Toronto, will undergo considerable alterations to her machinery this season at the hands of the Bertram Engine Works. The two present fire-box boilers, which are allowed 65 lbs. per square inch, will be removed, and replaced by one "Scotch" boiler 11 feet diameter, with a working pressure of 130 lbs. per square inch. This boiler will be fitted with a complete installation of the "Howden Hot Air Draft," in which the air is considerably heated by the escaping funnel gases before being forced into the ashpits. The present cylinders, which are 26 and 48 inches diameter, will be replaced by new ones of 19 and 40 inches diameter, the rest of the engine remaining practically as at present. The results anticipated are an increase of power, economy of fuel, both as regards quality and quantity, less weight of boiler, and more stowage room in the ship. As this is the first installation of the "Howden" draft on a Canadian lake vessel, it will be watched with interest. The work is under the supervision of A. P. Rankin, consulting engineer, of Toronto.

CHICAGO forwarders have sent out the following circular:—"It is our intention to put on three boats from Chicago to Parry Sound, the capacity of which will be in the neighborhood of 3,000 tons each, which will call at Milwaukee; also, two boats from Duluth, with about the same capacity. At Chicago we have leased a dock between the Ogdensburg Transit Company and the Lehigh Valley Transportation Company's dock, on which there is being erected a warehouse about 125 feet long, with an average width of 110 feet. At Parry Sound we have an elevator now ready for the handling of grain, with a capacity of about 1,250,000 bushels, and will have a warehouse 600 feet long by 80 feet wide, also a flour house 600 feet long by 80 feet wide, together with 2,500 feet dockage accommodation, on a 22-foot water line. We are also building at Coteau Landing, on the St. Lawrence river, at the mouth of the Soulanges Canal, a transit elevator, of 500,000 bushels' capacity, which will handle 240 carloads a day, also a warehouse and docks of sufficient dimensions for the handling of flour and package freight, our idea being to float our grain and package freight to Montreal and deliver alongside of the ocean vessels in Montreal harbor."

Mining Matters.

OIL has been struck at Croton, Bothwell county, Ont. The field is said to extend over an area of several miles. Some splendid wells have been struck on the town line of Zone and Camden.

THE Hall Mines Co. has closed a contract with the Dominion Wire Rope Company, Limited, Montreal, for 10 miles of wire rope for its cable way from the mines to the smelter. Its weight will be about 40 tons, and it will be made in six sections of over 1½ miles in length, for convenience in handling.

WHAT is known as the Dickenson mine in Michipicoten, Ont., has been sold to an English syndicate. George Fee, and J. J. Mackey, of North Bay, and J. L Caverhill, Montreal, were the vendors. E. A. Bremner, an English mining expert, acted for the syndicate. This claim was the first discovered in the Wawa, Ont., district.

CONSIDERABLE excitement has been caused in the county of Megantic, Quebec, by the discovery of gold on the banks of the Bullard Brook. The discovery was made late in the autumn, and several pits have been sunk, and in every case gold in small quantities has been found in the black sand that seems to be scattered over the whole of the flats.

THE annual meeting of the shareholders of the Intercolonial Coal Mining Company, Limited, took place recently, in Montreal. The sales of coal and coke, for the year ending Dec. 31st, 1897, amounted to 186,654 tons. The following were elected directors of the company for the ensuing year, viz.: James P. Cleghorn, president; H. S. MacDougall, W. M. Ramsay, Thomas Wilson, E. Goff Penny, M.P.; A. W. Hooper, R. MacD. Peterson, Charles Fergie, vice-president, and Wm. J. Nelson.

IN a report to Arch. Blue, director of the Bureau of Mines, Ontario, Prof. De Kalb, the new professor of mining engineering at Kingston School of Mining, says that the corundum in the counties of Hastings and Renfrew is very rich. Tests have been made showing that concentrates may be made giving ninety-two to ninety-four per cent. of corundum, and as the commercial standard of purity only requires eighty per cent. of corundum, it appears that this limit can be easily passed. Another thing that he says is that there is little difficulty in separating the corundum from the magnetite.

THE Geological Survey of Canada has just issued a summary of the mineral production of Canada for 1897, which, without being final—some of the figures not being obtainable just at present—is based on a general knowledge of the progress made in the various industries, and is sufficiently accurate for all practical purposes. The report shows that the value of the gold produced amounted to $6,190,000; of copper, 13,300,802 pounds were produced, value, $1,501,660; of lead, 39,018,219 pounds, value, $1,396,853; of nickel, 3,997,647 pounds, value, $1,399,176; of silver, 5,558,446 ounces, value, $3,322,905; of iron ore, 71,451 tons of two thousand pounds, value, $178,716; of mercury, 688 pounds, value, $324, and of platinum a value of $6,600. The report will be taken up fully in a later issue of THE CANADIAN ENGINEER, when the production in the United States will also be given, so that the relative increase in the two countries may be considered.

Personal.

WE regret to state that Wm. Hamilton, manager of the St. Lawrence Foundry, Toronto, was stricken with paralysis recently.

WM. MCLEAN, of the McClary Manufacturing Co., Limited, London, has gone to take charge of the company's office in Winnipeg.

P. S. ARCHIBALD, ex-chief engineer of the I.C.R., is engaged by Sir Charles Tupper as chief engineer of the Klondyke Mining Company.

T. H. WHITE, St. Thomas, Ont, has been appointed chief engineer for the new line of railway to be built from the Stikine River to Teslin Lake.

HENRY BUDDEN, vice-president and managing director of the Intercolonial Coal Company, of Pictou, N.S., has resigned that office on account of ill health.

JAMES WARNOCK, one of the most prominent citizens of Western Ontario and a leading manufacturer in Galt, Ont., proprietor of the Galt Edge Tool and Axle Factory, died at his home the 5th February.

W. A. CARLYLE, British Columbia provincial mineralogist, has handed in his resignation, to take effect April 1, when he will leave for Rossland to accept the mining superintendency of the British America Corporation.

RICHARD G. MCCONNELL, geologist of the Dominion Geological Survey, has been appointed mineralogist of the British Columbia Government at a salary of $4,000. Mr. McConnell has been with the Geological Survey since 1879, when he graduated from the science school of McGill University.

IN attempting to remove a piece of wood that had stuck fast in a bed planer, Norton Olds, employed in the Mann Manufacturing Co.'s works, Brockville, Ont., accidentally placed his right hand in the knives, which gradually drew the arm in, cutting it off by inches to within a short distance of the shoulder.

MRS. ANN OWEN GREENING, widow of the late Benjamin Greening, founder of the B. Greening wire works, Hamilton, Ont., died at the residence of her daughter, Mrs. R. H. Merriman, Hamilton, recently, aged 88 years. Her husband died 21 years ago. Five sons and two daughters survive her.

CHAS. B. BROWN, of the Ontario Rolling Mills, Hamilton, Ont., has gone to Tacoma, Washington, to accept the position of superintendent of the Western Iron and Steel Company. Before leaving he was presented with an address and a purse of gold by his fellow employees of the rolling mills.

CHAS. DAWSON, who for the past five years has been Works Superintendent for the Central Bridge and Engineering Co., Peterboro, Ont., and was formerly with the Canadian General Electric Co., as master mechanic for the Engineering Department, has resigned his position with the former and has accepted the position of Assistant Superintendent with special charge of all Machine Tool Work for the Dominion Bridge Co., Montreal.

WILLIAM HOLTBY, mechanical engineer of the Canada Atlantic Railway, Ottawa, was accidentally killed at Coteau Junction, Que., Feb. 23rd. He was superintending the replacing of a snow-plough on the track, when he slipped and fell under the train. Mr. Holtby had been a resident of Coteau Landing during the construction of the Canada Atlantic Railway transfer, of which he was the foreman. At the inquest, the jury brought in a verdict that deceased was the victim of an accident due to his own imprudence.

ALEX. DUFRESNE, one of the engineers on the Soulanges Canal, had a narrow escape from drowning Feb. 25th, while sounding for the depth of the water at the head of the canal. Mr. Dufresne, together with A. G. Grant, another engineer, was engaged with his instruments, when the ice suddenly gave way, carrying him with it. Mr. Grant, at the risk of his life, seized Mr. Dufresne and succeeded in pulling him out of the water. The place was a dangerous one, being 25 feet deep and at the head of the Coteau rapids.

LITERARY NOTES.

We have received the "Transit," a pamphlet of 170 pages, published by the engineering society of the State University of Iowa, U.S. It contains some valuable and interesting papers on engineering topics, chiefly by graduates of the University.

We have before us the Proceedings of the Seventh Annual Convention of the Association of Railway Superintendents of Bridges and Buildings. It contains in 275 pages a number of valuable papers profusely illustrated.

The "Mining Resources of Canada" is a pamphlet of about a dozen pages of printed matter and as many more of handsome photo-engravings, issued by the Department of the Interior, Ottawa. A great many statistics are given of the mineral productions of Canada in the past and information about the mineral regions. A large map of the Dominion is also included.

FIRES OF THE MONTH.

Feb. 2nd.—McIntyre block of stores and offices, Winnipeg, Man. Loss about $500,000; to be rebuilt.——Feb. 13th.—Ontario Rolling Mills, Hamilton, Ont., the main building destroyed; the loss was $16,472. The machinery, etc., was insured for $28,000, and the building, owned by the Grand Trunk, for $6,000.——Feb. 16th.—The power house and plant of the Markham, Ont., electric light and waterworks; loss about $3 500.——Feb. 16th.—George Middleditch's foundry and machine shop, Bothwell, Ont. Loss about $7,000.——Feb. 17th.—Waterloo, Ont., Manufacturing Co.'s foundry; damages, $400.——Feb. 19th.—Bismarck cheese factory, near Wellandport, Ont., burnt down; loss about $2,500.——Feb. 19th.—Barrel factory, Lequille, N.S., property of the Union Bank of Halifax; loss about $15,000.——Feb. 20th.—Flour mills, Burlington, Ont., run by W. H. Finnemore, owned by Estate P. Redpath, Montreal; loss about $10,000.——March 4th.—The Goold, Shapley & Muir windmill and bee supply factory, Brantford, Ont.; loss about $20,000.

—A hot air radiator, of special value to all users of wood burning stoves or furnaces, has been invented by R. W. Biggar, Sorauren ave., Toronto. It is a drum to be applied to a stovepipe in the ordinary manner, but, unlike any other heating drum we have seen, it sucks up the cold air from the floor of the room and throws it out at the top of the drum, thus keeping all the air in the room in circulation, and abolishing finally cold floors.

—The Hamilton Acetylene Gas Machine Company's generating apparatus, of which an advertisement appears on another page, possesses many features which make it of great value. The patent water spray, by which the water is supplied to the carbide in the generator, is a special feature of great interest. A further description of this machine will be given in the next issue of THE CANADIAN ENGINEER.

SOME EXPERIMENTS ON THE CONDENSATION OF STEAM.*

By H. L. Callendar, M.A., F.R.S., Professor of Physics, and J. T. Nicolson, B.Sc., Professor of Mechanical Engineering of McGill University, Montreal.

Part I.

As the result of some experiments by electrical methods on the measurement of the temperature changes of the walls and steam in the cylinder of a working steam-engine, which were made at the McDonald Engineering Building of McGill University in the summer of 1895, the authors arrived at the conclusion that the well-known phenomena of cylinder condensation could be explained, and the amount of condensation in many cases predicted from a knowledge of the indicator card, on the hypothesis that the rate of condensation of steam, though very great, was not infinite but finite and measurable. An account of these experiments was communicated to the Institution of Civil Engineers in September, 1896, and will, it is hoped, be published in the course of the ensuing session. In the meantime, the authors have endeavored to measure the rate of condensation of steam under different conditions by a new and entirely different method, with a view to verify the results of their previous work, and also to estimate the influence, if any, of the film of water adhering to the walls of the cylinder.

In considering the condensation of steam on a metal surface it is usually assumed that the surface exposed to the steam is raised up to the saturation temperature corresponding to the pressure of the steam, and that the amount of condensation is limited by the resistance of the water films to the passage of heat from the steam to the metal and from the metal to the water. If the steam contains air, there may also be a considerable resistance due to the accumulation of a film of air on the surface, but it is comparatively easy to exclude this possibility in experimental work.

In the steam-engine experiments, above referred to, it was practically certain that the water film due to the cyclical condensation never exceeded one-thousandth of an inch in thickness, and that the resistance offered by it was unimportant. At the same time, it appeared clear that the temperature of the surface of the metal at its highest was considerably below the saturation temperature of the steam: a condition which could only be explained by supposing the rate of condensation of steam on a surface to be limited by some physical property of steam itself, apart from the resistance of the condensed film of water. Interpreted in this manner, the experiments led at once to the conclusion that the rate of condensation at any moment was simply proportional to the difference of temperature between the saturated steam and the surface on which it was condensing.

The limit thus found was shown to be capable of explaining many of the phenomena of cylinder condensation in a rational manner; but the method by which it was established was of an indirect and somewhat intricate character, and appeared to require some simple and more direct confirmation.

If the rate of condensation of steam were really infinite, it should be possible by a suitable modification of the surface-condenser method (i.e. by getting rid of the water films on the outside of the tubes) to obtain values of the condensation considerably in excess of those given by the formula deduced from the temperature cycle observations.

To accomplish this, it is necessary to eliminate as completely as possible the resistance to the passage of heat through the water films between the steam and the metal, and between the metal and the circulating water, and at the same time to measure as accurately as possible the temperature of the metal.

These considerations led to the form of apparatus which was employed. The resistance to the passage of heat from the metal to the condensing water in this apparatus is practically eliminated by employing a thick cylinder, 5 in. diameter and 2 ft. long, with a screw thread cut on its outer surface. Water from the high-pressure mains is forced to circulate round this surface with a very high velocity in the narrow space between the cylinder and the surrounding tube. In this manner it is possible to obtain a very uniform temperature for the external surface differing but little from that of the circulating water.

If the cylinder is made sufficiently thick, its temperature may be approximately determined at any depth by inserting mercury thermometers. It was intended at first to use thermo-couples for this purpose, but the apparatus in this form would have been unsuitable for students' use in the ordinary course of laboratory work, which was one of the primary objects in view in the construction. It would also have been desirable to make the cylinder of nearly pure copper, which would have reduced the resistance of the metal to the lowest point. The authors were compelled, however, to content themselves for the time with cylinders of cast iron and of mild steel.

The internal surface of the cylinder, upon which the steam was condensed, was a hole one inch in diameter, drilled in the solid metal. In order, as far as possible, to minimize the resistance of the surface film of condensed water, a revolving brush was constructed of very thin strips of steel to wipe the surface five or six times a second. This wiper was found to wear in a very short time to so perfect a fit and the water film must have been so energetically stirred that its resistance to the passage of heat must have been far less than that of the best conducting metal, when there was perhaps some small film present.

Under these conditions, if the rate of condensation of steam were infinite, it should have been possible to obtain a rate of condensation many times greater than the limit deduced from the cylinder-condensation experiments above mentioned.

On making the experiment, however, it was found that the wiper made very little difference to the amount of condensation. With the wiper revolving at the rate of 160 per minute, the condensation was increased by about 5 per cent. on the average of several experiments. It may be concluded from this that the drops of condensed water with which the surface is partially covered are in such rapid motion that they do not appreciably obstruct the passage of heat from the steam to the metal. In fact, Prof. Callendar actually found that the drops increased the condensation. A film of the same average thickness, if it were absolutely quiescent, and if its conductivity, as generally estimated, were only one-hundredth of that of cast-iron, would no doubt prove a serious obstacle; but, as a matter of fact, the viscosity of water at these temperatures is so small, and the motion so rapid, that the drops cannot be treated as a quiescent film.

The temperature at various distances from the inner surface of the cylinder was determined by means of mercury thermometers inserted to a depth of 8 in. or 9 in. in holes drilled parallel to the axis. From the temperatures so observed the conductivity of the metal and the temperatures of its inner and outer surfaces could be approximately inferred. It was found, however, that the presence of the holes interfered materially with the flow of heat through the metal, and that the readings of the thermometer under these conditions were not altogether trustworthy.

From a number of observations on the cast-iron cylinder a conductivity of 5.5 thermal units Fahr. per square ft. per minute per deg. Fahr. per inch was deduced, a result which agrees very closely with the authors' previous determination by a different method. For the steel cylinder a conductivity of 5.8 was similarly deduced. These results apply to a mean temperature of about 140 deg. Fahr., and are much lower than the values generally assumed for iron.

In order to verify the previous results as to the rate of condensation of steam derived from the steam-engine experiments, the temperature of the inner surface of the metal was calculated on the assumption of a rate of condensation equivalent to 0.74 thermal unit Fahr. per second per square foot per deg. Fahr. difference of temperature. The values so found agreed with the observed temperatures within the limits of error of the observations. Owing to the inferior conductivity of the iron the test was not absolutely conclusive, as the difference of temperature between the steam and the surface rarely amounted to as much as 30 deg. With a cylinder of pure copper, and thermo-couples for determining the temperature at a given depth, it should be possible to obtain a more certain confirmation by this method.

In performing the experiments a number of variations in points of detail were introduced from time to time. The flow of the circulating water was varied in velocity, and directed in different ways. In order to secure uniformity in the distribution of temperature measured in different directions from the centre, the spiral circulation was found to be essential. In the second apparatus the screw thread was at first replaced by a baffle-plate, which was intended to direct the water into a spiral course, but the results found were unsatisfactory.

* A paper read at the annual meeting of the Canadian Society of Civil Engineers.

In some cases steam was admitted from the top of the apparatus, and in other cases from the bottom. With the steam supply at the bottom, it was found that condensed water refused to drain down the vertical 1-in. tube in opposition to the current of steam, although the maximum velocity of the steam could not have exceeded 10 ft. per second.

The following set of observations, each of which represents the mean of several taken on similar conditions, will sufficiently indicate the general nature of the results:

The temperatures of the metal at distances of 1 in., 1.5 in., and 2 in. from the axis of the bar were observed by means of mercury thermometers, which were very carefully centred by small iron washers in holes filled with mercury. The hole fitting the bulb of the thermometer was 3-16 in. in diameter. The other holes were 5-16 in.

It will be observed that in this particular set of experiments the temperatures at 1 in. in the metal, when calculated to agree with the assumed rate of condensation, are all too low as compared with those observed, whereas the temperatures similarly calculated at 1.5 in. are all too high. This might at first sight appear to indicate a very rapid diminution of the conductivity with rise of temperature; but after making various tests the effect was traced partly to the disturbance of the heat flow caused by the presence of the holes, and partly to differences of density of the bar in directions at right angles. The latter differences were not observable in the case of the cast iron.

The observations taken at different pressures do not indicate any marked difference in the rate of condensation per degree second. These results, so far as they go, are in agreement with the authors' previous work, but they hope to be able to obtain more conclusive evidence.

Condensation Results Summary. Mild Steel Bar. Wiper Removed.

1. With a short length of condenser and a very free escape of steam, the condensation observed was equivalent to 22.2 thermal units Fahr. per square foot per second, for a difference of temperature of 28.5 deg. Fahr. between the steam and the metal surface. This is equivalent to a rate of condensation of

AN ELECTRICAL METHOD OF MEASURING THE TEMPERATURE OF A METAL SURFACE ON WHICH STEAM IS CONDENSING.

By H. L. Callendar, M.A., F.R.S., Professor of Physics, McGill University, Montreal.

Part II.

The object of the following experiments, which were made at the McDonald Physics Building with a different apparatus, was the measurement of the temperature of the metal surface itself by a more direct and accurate method. It was also desired to verify as exactly as possible whether the rate of condensation of steam at atmospheric pressure was the same as at the higher temperatures and pressures at which most of the preceding experiments were made.

The condenser used for these experiments was a very thin platinum tube, ¼ in. in diameter and 16 in. long. The thickness of the tube was only six-thousandths of an inch, and the greatest difference of temperature between its inner and outer surfaces at the maximum rate of condensation observed in the experiments could not have been greater than ¼ deg. cent.

The mean temperature of the metal itself was determined in each case by measuring the electrical resistance of that portion of the tube on which the steam was condensing. The author has had considerable experience in the employment of this method, which, moreover, is very easily applied if suitable apparatus is available.

The platinum tube was enclosed in an outer tube of brass or glass, and steam was admitted to the space between the two tubes. A steady current of condensing water was maintained through the platinum tube. The amount of condensation could be inferred by measuring the flow of water, and observing the difference of temperature between the inflow and the outflow. In many cases the condensed water was also measured. Applying a small correction for radiation, the two methods always agreed within one-half of 1 per cent. The pressure of the steam in the outer tube, which was never far from the atmospheric, was observed by means of a mercury column.

The conditions of the experiment as to flow of water and steam, size and length of the external tube, etc., could be varied within certain limits. The following is a summary of the more interesting results obtained:

For Sale Cheap

A New 100 Kilowatt 125 Volt Multipolar, Direct Current Dynamo

Latest steel frame type, with iron clad armature.

A most complete set of Station Attachments. Suitable for Incandescent Lighting, with a capacity of 2,000 16-candle power lamps, or for power or electro-chemical purposes; has never been used only for a test.

For particulars apply to E. H. HILBORN, 74 Brunswick Avenue, Toronto, or to JOHN TOLMIE, Kincardine.

The Ontario People's Salt and Soda Company, Limited

A Handsome Catalogue

"The Steele, Briggs Seed Co., Limited, have issued their annual catalogue in the shape of a very handsome volume of over 100 pages. The covers are beautiful, front and back, both bearing exquisite floral designs. The front page contains pictures of sweet peas and of the new pink Roamer rose, while the back has two magnificent pictures of two new giant orchid flowering, Italian cannas, the Italia and the Austria. The contents of the volume are as interesting and as up-to-date as usual, and contain some tempting offers"—Toronto Globe, Feb'y 9, 1898.

ROADBED CONSTRUCTION.

ARTICLE 28.—LAYING OUT AND MEASURING WORK.

Cross-sections should be taken at such intervals that the prismoid between two adjacent ones will have planes as boundaries on a top surface with longitudinal convolutions only, extending in straight lines from one section to the other; to do this quickly and without unnecessary sections is a matter of experience and visual judgment, requiring the personal attention of the engineer. The slope stakes should be marked on one side with the cut or fill and on the other with the distance from the centre line; some engineers also write the station (chainage) on the slope stakes. These stakes are put in at every 100 feet in light work and on tangents, but on curves and heavy work they should be put in every 25 or 50 feet, depending on circumstances, and on all side-hill work liable to slip the sections should be carried up the hillside 200 or 300 feet to points beyond any danger of movement, and should be taken before excavation has been commenced.

*This series of papers will be issued in book form as soon as they have appeared in THE CANADIAN ENGINEER.

There are two methods of keeping notes in use in Canada; in the first, each rod reading is entered in a separate line and the corresponding cut or fill reduced from the grade elevation; in the second method the difference between height of instrument and grade is called "grade rod," and the rod readings are subtracted mentally from it, and the corresponding cuts or fills are recorded, consecutively, on one line of the book in the form of fractions, with the distances from centre line as denominators. It is evident that the first method is more laborious and fills much more space in a note book, and is not so convenient for plotting, but, on the other hand, the reductions can be checked afterwards, and are legal documentary evidence, whereas the second method is entirely one of convenience and leaves great chances for error by careless mental subtraction, which cannot be duplicated, and the note books are, therefore, not very strong evidence in a law court.

Plate XXI

22 L..	..	..	..	10.2	301.0	..	8.0	..	S. S.

(II) United States Method.

Station.	B. S.	H. of I.	F. S.	Grade.	Grade rod.	Left.	Centre.	Right.
102...	...	311.20	...	293.0	18.2	(s.s.) $\frac{+8.0}{22.0}$ $\frac{+8.5}{3.0}$	$\frac{+8.0}{0.0}$	$+7.5$ $+\frac{6.0}{8.0}$ $+\frac{7.0}{20.0}$ (s.s.)

The greater simplicity and convenience of the second method commend it to general use in spite of its drawbacks.

On some roads it is customary to take sections after the work is done, and pay for the actual quantities excavated; in others, the slope lines are adhered to and every endeavor is toward the full section taken out. It is probable, however, that the former method is more satisfactory to all concerned, although giving a little extra work to the engineering staff.

Structures need to be staked out twice, once for the foundation pit and again for the laying out of masonry, and of course, on all important structures, measurements and levels are given very frequently as the work progresses, both as an aid and a check to the contractors. A separate note book called a "structure book" should be used, and in it recorded, from day to day, notes of actual sizes, heights and measurements of all structures, and a duplicate office copy also kept up to date for fear of losing the field book. This structure book should include notes on all timber, stone and iron structural work, and will be a valuable aid in case of disputes involving quantities, it will also enable a large scaled profile being made for the maintenance department showing the exact chainage and elevation of each foundation and portion of structure. The necessity for absolute accuracy in laying out, measuring and calculating the quantities in all structures and grading cannot be too firmly impressed on the young engineer; all office calculations should be done in duplicate and preferably by different persons, as one cannot be very sure of a check on one's own work.

Cross Section Areas may be calculated in at least three or four ways, (1) where only a three-level section is taken, as in Fig. 77, the area of the section is evidently made up of triangles and is:

$$\text{Area} = \left(d \times \frac{S_1 + S_2}{2}\right) + \left(\frac{b}{2} + \frac{d_1 + d_2}{2}\right) \quad \ldots\ldots\ldots (1)$$

(2) On rougher ground where more than three surface readings are necessary this method fails and must be replaced by more tedious ones, quite ordinarily Fig. 78 illustrates the one adopted, and consists in taking out the sum of all the trapezoidal areas, $A.A._1D._1D.E.F.G.H.A.$ and deducting the area of the two triangles $A.A._1B.$ and $D.D._1C.$

(3) By careful plotting, irregular areas can be taken out quite accurately with a polar planimeter.

(4) By Eckel's formula, which can be used without plotting the sections, and is equally adapted to the easiest or most difficult rectilinear areas. This formula, which is mathematically correct, is: "If the corners of any rectilinear polygon be referenced by rectangular co ordinates to any origin, then if the ordinate of every corner be multiplied by the abscissa of the next corner. and so on around the polygon, and these products added together; and if the ordinate of every corner be again taken and multiplied by the abscissa of the next corner, passing around the polygon in the *reverse* direction, and these products added together, then the area of the polygon is equal to one-half of the difference of these two sums." As an example, in Fig. 79 the area of the polygon is

$$\tfrac{1}{2}\{[(a \times d) + (c \times f) + (-ex - h) + -g \times -l) + (k \times b)] - [(a \times -l) + (k \times -h) + (-g \times f) + (-c \times d) + (c \times b)]\} \quad \ldots\ldots\ldots (2)$$

or,

$$\tfrac{1}{2}\{(a \times d) + (c \times f) + (c \times h) + (g \times l) + (k \times b) + (a \times l) + (k \times h) + (g \times f + (c \times a) - (c \times b)\} \quad \ldots\ldots\ldots (3)$$

In which great care must be taken to use the correct plus and minus signs. In railway work, this is much simplified by having all the area above the axis $XX.$, and in very irregular areas, which are met with in cuts that have slipped in as in Fig. 79, the area can be quickly taken out, thus, as follows:—

$$\text{Section} = \frac{+8.0}{-22.0}\cdot\ \frac{+8\,5}{-3.0}\cdot\ \frac{+8.0}{0\,0}\cdot\ \frac{+7.5}{+2.0}\cdot\ \frac{+6.0}{+8.0}\cdot\ \frac{+7.0}{+20.0}\cdot$$

$$\frac{+3.0}{+13.0}\ \ \frac{+0.0}{+9.0}\cdot\ \ \frac{+0.0}{0.0}\cdot\ \ \frac{+0.0}{-9.0}\cdot\ \ \frac{+2.0}{-14.0}\cdot\ \ \frac{+4.0}{-16.0}\cdot\ \ \frac{+8.0}{-22.0}$$

$$\text{Area} = \tfrac{1}{2}\{-24.0 + 16\,0 + 60.0 + 120\,0 + 91.0 + 27.0 - 32.0 - 88.0 + 128.0 + 56.0 + 18.0 - 60.0 - 56.0 - 12.0 + 24.0 + 187.0\} = 227.5 \text{ square feet.}$$

Thus arriving at a c rrect result without plotting sections, and by a mechanical sort of process, which is a safe one to place in the hands of a comparatively unintelligent rodman; for the purpose of checking calculations, it is not appreciably more or less rapid than by taking out areas by method. (2)

QUANTITIES.

The use of tables and diagrams is a great aid in taking out approximate quantities, so that in various handbooks may be found the volume of 100 foot prismoids of level sections, of various heights, slopes and widths of road-bed, and this has been extended in Wellington's earthwork diagrams, etc., by giving the volumes of 100 foot prismoids where the sections, although not level, are of the three-level type, having a separate height at the centre and each slope stake, and as in easy sections this is all that is taken the diagrams are very useful. More accurate calculations of volumes of excavation or embankment may be made in three ways: (1) The prismoidal formula, which is the only one that is mathematically correct, is as follows:—

$$\text{Volume} = L \times \frac{A + 4A_1 + A_2}{6} \quad \ldots\ldots\ldots (4)$$

Where L = length of prismoid A and A_2 = end areas and A_1 = middle area (which must be calculated by interpolating the middle heights).

A proof of this formula may be found in any mathematical text book, but a neat adaptation of the formula for three-level sections is given by Mr. G. H. White in *Engineering News*, April, 1895 (see Fig. 80).

$$\text{Volume} = \tfrac{1}{6} L\left\{A + 4A_1 + A_2\right\} =$$

$$\tfrac{1}{6} L\left\{\left(\frac{W.d}{2}\right) + \left(\frac{b}{2} \cdot \frac{H+h}{2}\right) + \left(\frac{W_2.d_2}{2}\right) + \left(\frac{b}{2}\frac{H_2+h_2}{2}\right) + 4\left[\tfrac{1}{2}\left(\frac{W+W_2}{2} \cdot \frac{d+d_2}{2}\right) + \frac{b}{2}\left(\frac{\frac{H+H_2}{2} + \frac{h+h_2}{2}}{2}\right)\right]\right\} \quad \ldots\ldots (5)$$

$$= \tfrac{1}{6} L\left\{\left(\frac{W.d}{2} + \frac{W.d}{2} + \frac{W.d_2}{2}\right) + \left(\frac{W_2 d_2}{2} + \frac{W_2 d}{2} + \frac{W_2 d_2}{2}\right) + \frac{b}{4}\left(H + H_2 + h + h_2 + 2H + 2H_2 + 2h + 2h_2\right)\right. \quad \ldots\ldots (6)$$

$$= \tfrac{1}{6} L\left\{W\left(d + \frac{d^2}{2}\right) + W_2\left(d_2 + \frac{d}{2}\right) + \tfrac{3}{4}b(H + H_2 + h + h_2)\right. \quad \ldots\ldots (7)$$

and if we have a definite slope which we call s. (say $1\frac{1}{2}$ to 1 for earth, or $\frac{1}{4}$ to 1 for rock), we will have

$$H + H_2 + h + h_2 = W + \frac{W_2 - 2b}{s} \quad \ldots\ldots (8)$$

and the volume equation becomes

$$= \tfrac{1}{6} L\left\{W\left(d + \frac{d_2}{2}\right) + W_2\left(d_2 + \frac{d}{2}\right) + \tfrac{3}{4}\frac{b}{s}\right.$$

$$(W + W_2 - 2b) \quad \ldots\ldots (9)$$

from which it will be seen that the volume may be obtained by having the slope stake distances of the two end sections (W and W_2), the centre cuts (d and d_2) the roadbed width (b), and slopes (s), thus eliminating the determination of the middle area from the calculation.

(2) Mean areas, which custom has established as the one to be ordinarily used, because of its simplicity, is merely, volume $= L \frac{A+A_2}{2}$ .....(10)

where A and A_2 are the two end areas, the error involved in this formula is $+ \frac{1}{6} L (h-h_2)^2 s$. Where h and h_2 are the two centre heights, and s = slope of earth work, it is evidently = zero when $h=h_2$ and increases with their difference.

(3) Middle area volume is given by

Volume $= L+A_1$ .....(11)

Where A_1 = area of section midway between the ends of the prismoid.

The error involved in this formula is $+\frac{1}{12} L(h-h_2)^2 s$, being one-half as much as in the formula for mean areas, and also disappearing.

When $h=h_2$—and although equation (11) is more accurate than equation (10), it is not used, because once the middle area has been determined, the prismoidal formula is easily applied and still more accurate. There is another reason why formula (10) is not objectionable, that, in general, the profile of a line is convex in cuts, and concave in fills, and any system of sections, no matter how carefully taken will, as an average, need a little allowance for this rotundity between sections.

At points where the cut changes to a fill there should be two grade pegs determined (see Fig. 76) and cross-sections taken at these points, this makes the first volumes in cut and fill always pyramidal, there is no necessity for a centre grade peg, unless the distance from one grade peg to the other is excessive.

Borrow pits should be carefully cross-sectioned from some well defined base line before excavation is permitted, and, if at all possible, it should be made imperative that these pits before being abandoned should be left in good shape for final cross-sections and for drainage; undrained borrow pits are unsightly, a menace to health, and difficult, often, of measurement. There is another matter in this connection which should be well attended to, *i.e.*, proper referencing of alignment hubs; this may be done by cross lines fixed by hubs, trees, etc., or by right-angled lines and steel tape measurements, but in whatever way accomplished, considerable judgment is required to place the references out of harm's way and at the same time reasonably available; in side-hill cross-sections made after excavation great precision is required in this respect to prevent serious error.

Article 29.—Methods of Payment and Classification of Materials, etc.

There are occasional instances of railway companies of some financial strength and progressive growth carrying on construction under their own management, with their own plant and by day labor, but such instances are not frequent, and in general we may look to responsible contractors for the rapid execution of this kind of work requiring experience, undertaking risk, and with considerable capital as plant continually wearing out. Occasionally such work is taken by contractors at so much per mile, within limits of curvature, grades, style and locality, but as the element of risk is great the price is correspondingly high. Only approximate estimates are furnished, and the experienced judgment of the contractor to size up the class of material to be met with is his chief reliance. Such contracts are apt to be made when the railway company and the contractors are more or less identical.

Again, at times, contracts are taken in which such as timber, stone and iron are specified as to quality and price *pro rata*, but the excavation is unclassified and an average price per cubic yard is given, the contractor again taking chances, and being, by this method, unable to alter the location, his risk is great and price high enough, on the whole, to cover the risk; this has led to what is, at present, the general method of letting contracts for excavation, namely, to define certain classes of material as rigidly as possible and fix prices for each class, the usual divisions are solid rock, loose rock, hard-pan and other cemented material, and earth. As the dividing lines between these classes are purely arbitrary they need to be defined for all possible contingencies, which is a difficult matter. An engineer is always, although in the employ of the railway company, more or less an arbitrator, and he should endeavor to be just to all; theoretically he should always live up to the strict letter of the contract, and ordinarily this is the only course to pursue, but there are cases in which contractors, in their eagerness to obtain contracts, take them at too low prices, or they may strike some very difficult cuts which will not classify very highly if the specifications are adhered to, and in such cases it is usual to allow percentage classifications based on a fair cost of doing the work, *e.g.*, a heavy cutting composed of a mass of small boulders closely cemented together would only classify as hard pan, but often must be excavated entirely by drilling and blasting, and in such a case percentages, at least of rock, would be quite justifiable.

This idea of *helping out* a contractor, however, is a very pernicious one, and should only be done for good cause, where the recipient is worthy of it by his economical handling of the work, and with full knowledge and consent of the railway company. The vigilant watch and full knowledge of the various classes of material met with in excavation and the most economical methods of handling them, form one of the most important duties that a railway engineer has to perform, needing, moreover, a knowledge of men as well as ways and means. The calculation of quantities in structures should be made very minutely and in detail, as the prices are so much higher per unit than those of excavation; but the method to be used will depend on the terms of the contract and the individuality of the engineer. In some cases payment is made on bills of timber furnished, and on general plans of masonry, while in others the actual timber used and the masonry as built are the basis of payment. In the case of timber this latter method should include payment, as timber delivered, for all pieces cut off either from piles or timber, so long as the material used was as per bill given.

Quantities of earthwork should always be measured in excavation, for no one can determine accurately the shrinkage of fills, especially as only a portion of it takes place while construction is in progress, and continues for a year or two depending on the method of forming the bank. The total shrinkage is fairly well known, being about 5 per cent. for sand, 10 per cent. for clay, and 15 or 20 per cent. for loam; while rock expands 50 to 75 per cent., depending on the size of the pieces, and such figures modified according to the age of the bank will be sufficiently accurate for monthly estimates, but not for final ones. It is more laborious, often, to measure irregular borrow pits, but by insisting on these pits being shaped up before being left, the extra labor is not so very great and is the only really reliable way, the chief value of embankment quantities being to aid in a proper dis-

tribution of material from cuts, to enable overhaul calculations being made, and for approximate estimates where errors of 5 per cent. or even more are not objectionable, as the company, in its monthly payments to contractors, reserves 10 or 15 per cent. for just such exigencies. In taking monthly estimates, the only certain method is to make each one a total estimate in fact as well as in name, and derive the current estimate by deducting the total one for the month previous from it, that is, never take notes only of what is thought to have been done during the month, for nothing is more difficult or more apt to lead to error—whereas if the total work done or material delivered at each point is noted, the errors of each month are eliminated in the next one—the extra labor involved in this is usually insignificant.

Specification for Excavation.—Materials excavated will be classified as earth, quicksand or dry hard-pan, loose rock and solid rock. Earth includes everything except the other classes mentioned. Hard-pan includes all cemented clay or gravel, or any combination of these that it is not practicable to plow with a four-horse team. Loose rock includes all stone containing not less than one cubic foot, and masses of detached rock containing not over one cubic yard; also all slate, shale or other soft rock which can be removed without blasting, although blasting may be resorted to. Solid rock includes all loose rocks containing over one cubic yard, and all rock in place which requires drilling and blasting.

(N.B—.The earth and hard-pan are sometimes placed in one class as earth, at a higher rate, thus saving much contention.)

ARTICLE 30.—SURFACE DRAINAGE.

In addition to the provision for flow of water under or through the track, there is yet the question of track and slope protection which is of almost equal importance. Where, on side-hills, the surface flow toward the top of the cut slopes and toe of the embankment slopes is considerable, ample provision should be made to intercept it. In general, catch water ditches three or four feet wide, and one to one and one-half feet deep, should be dug so as to run in a continuous line along the upper side of the cuttings and embankments from each lateral watershed to the nearest culvert or stream—which should set back five or six feet, generally, from the edge of the slopes leaving a solid berm; the material from these ditches, cast on the lower side will form an additional protection. In very porous soils, these ditches may need to be lined with pitch or planked; but in any case will prevent that heavy washing down of cut slopes which, otherwise, fills up the track ditches and floats the track, making the roadbed soft.

The track (cut) ditches themselves should be turned into these catchwater ditches at the upper grade points, so as not to empty down along the toe of the embankment, eating it away; and in very wet cuttings, it may be necessary to run a farm tile about three feet under the track ditches and parallel to them to aid the drainage. In case of quicksand, which will soon fill up tiles, the tile must be covered with straw and laid with collars, or longitudinal round pole drains may be substituted for the tiles.

The slopes of cuttings themselves also need protection to prevent erosion; in ordinary cases the sowing of grass seed on the slopes of cuts and fills will answer the purpose, but where the cut slopes are wet and springy it may be necessary, in addition, to cut a series of diagonal ditches on the slopes to bring the water to the cut ditches by easy grades; in extreme cases the construction of a network of tiles on the slopes may be necessary to effect complete protection. Perhaps the most imperative matter of all is to have the ordinary cut ditches always cleaned out—free from boulders, ties, ballast, etc., which tend to accumulate during maintenance. The form which such ditches assume is of a wedge shape, with a slope from the track of about 3 to 1 and an outer slope the continuation of the cut slope. This form will tend to maintain itself better than one with a flat bottom and steeper slopes.

(Conclusion Vol. I.)

For THE CANADIAN ENGINEER.

SEWAGE DISPOSAL THROUGH THE ACTION OF BACTERIA.

BY W. M. WATSON, TORONTO.

Toronto and several other cities and towns, as well as private places, are contemplating putting in sewage works. Perhaps a little information, gathered from the leading bacteriologists, chemists and engineers, who have with the assistance of the best appliances been studying and experimenting on sewage for the past fifteen years, with the object of solving the knotty problem, viz., how to purify foul fluids, may be useful. My own experience in this connection will also be of interest.

Up to the present time precipitants of lime, powdered clay, alumina, ferrozone, sulphurous powder, sulphate of iron, and other chemicals, have been used to clarify or clean sewage by settling in tanks, generally extracting about a twentieth part of a pound of sludge per gallon of sewage treated, at a cost per head of population ranging from 25 to 75 cents, and often having considerable difficulty in disposing of the solids, even when expensive pumps, presses, and other machinery are used. The average composition of domestic sewage is: organic matter, 27.72 grains per gallon; nitrogen, 6.21; phosphoric acid, 1.17, and potash about 2.03 grains per gallon, which is principally in solution, and can only be removed by filters that contain numerous colonies of a very small rod-shaped bacteria that can be seen only by the assistance of a very powerful microscope. These organisms feed and thrive on the foul contents of sewage matter. Trade sewage may contain any chemical, and in some cases may need special treatment, which ought to be given it before it is allowed to enter the public sewers. Sewage heavily charged with grease may require a precipitant of bisulphide of carbon. Sewage from sugar factories which contains vegetable organisms, oscillaria alba, or beggiatoa, which act like ferments, rapidly decomposing, may require a magnesium chloride, quicklime and coal tar preparation, to extract its foul contents, and sewage from slaughter houses should have the blood and fat extracted before entering the public sewers.

To discharge clarified sewage that has only passed through settling tanks into fresh water is simply undoing the work done, because the dissolved putrefactive matter is held in solution after the solids are thrown down by the precipitants, and after being delivered into fresh water the dangerous microbes increase rapidly, and putrefaction is set up. Almost the same end is reached by allowing the sewage to enter fresh water after it has been carefully screened through a fine sieve, and it is probably more to the advantage of the public to allow sieved sewage to go in raw, than after it has been settled by the use of precipitants, because precipitants add somewhat to the chemicals held in solution, and make the sewage harder to purify.

Sewage placed under a microscope shows various decaying matters, multitudes of dangerous microbes, amoebiform bodies, infusoria, fungi, etc., including all the classes discharged from the skin and intestines of man and the animals. When water carriage is used to remove

excrements, it is usual to calculate upon a basis of about 156 lbs. of solids and 200 gallons of liquids from each one thousand of population to remove daily. The sewage from clothes washing is very dangerous.

Disposal of sewage by broad irrigation over the top of land is neither efficient nor profitable in cold climates, because it takes a large space, and only about two gallons per yard per day can be put on, even when vegetation is active, because of the tenacity of the soil in holding moisture. Vegetation only takes up the manurial deposits, and the bacteria in the land must extract the foul gases or poisons, which they cannot do when the air cells of the earth get choked with fat and dirt. Then the bacteria cannot secure aeration, and so becomes useless. During heavy rains and hard frosts, the land is totally worthless as a filter or absorber of foul matter. When either irrigation land or artificial filters become water-logged too long they become asphyxiated, the organisms cease to act and oxidation is suspended until air can again be introduced to the filtrate to give vitality to the bacteria. On that ground irrigation through land can only be a success when the position is high and dry, and the water can freely escape at a depth of over four feet, and when it is composed of sand and gravelly soil. Under these circumstances, it will act as a bacteria filter, and can be made to purify sewage all the year round, by laying perforated pipes about every two feet, so that the fluid will be evenly distributed over the land. The pipes may be laid about fifteen inches below the face of the land, out of the reach of the frost in winter, and out of sight in summer, to prevent any nuisance, and to allow the land to be cultivated. By so doing, the moist air rising from the sewage will aid the vegetation growing on the surface. When this system is adopted proper arrangements must be made to discharge the sewage through the pipes at stated periods and equal quantities, giving the land periods of rest and sufficient time to secure aeration, and to supply the air to the underground pipes, flues and air circulating shafts must be constructed so that every part of the irrigating land, gravel and sand, also the microbes lodging in it, may be sufficiently supplied with oxygen. A firm in Ireland mix a solution of soda with the sewage, which it is claimed gives the bacteria all the oxygen they require without wasting time aerating. This is described elsewhere.

The marked success lately of the scientists has shown that all purification of foul fluids, whether accomplished by fresh water, by farm land, or artificial filters, is done by bacteria, and every method used to purify sewage must have proper provision made to supply these microbes with oxygen. By scientific management these friendly bacteria, which are humanity's scavengers, can be coaxed to eat up all the dirt and impurities in the sewage and discharge it into the atmosphere in the form of non-injurious gases, and by so doing saving the expense of handling the sludge.

This narrows down the art of cleaning foul fluids into being able to cultivate, to breed and use friendly microbes to advantage. When this is accomplished and the ditritus screens, the preparative storage tanks and the bacteria filters stocked with the friendly microbes and set in motion, it afterwards costs little to manage the treatment plant, for it can be made fully self-acting, only requiring the ditritus removed from the screens, and the grit removed from the syptic preparing tank about once a year.

There are several sewage purifying works constructed on the system just described working at present, and it will no doubt be generally adopted when properly understood. What is named the syptic tank, is placed underground and arched over, made air-tight and kept dark. The town's sewage goes in at one end and is almost motionless for a day, and during that time the coarser particles in suspension become deposited, and the putrefactive bacteria contained in the sewage are disintegrated, and a large portion of the inferior microbes disappear along with the sediment, after which it overflows over the opposite end, and is passed on to the bacteria filters.

Where convenient, towns should have separate drains for the collection of sewage, and they ought to be divided into small districts, each having its own sewage works. By adopting this plan only small main sewers would be needed, a better grade could be given, the sewage would arrive at the works in a fresher state, and on that account would be easier to treat, it would not have time to putrefy in the pipes, and the sewers would not need so much flushing, and the large trunk sewers might be dispensed with. By the new method of sewage purification the district plan can be easily carried out, because the whole sewage plant can be placed underground in public squares or other convenient places, out of sight and totally free from smell or nuisance, there being no machinery required or sediments to remove, and the first expense of plant will be less than by the old systems, and the cost of management after the system is put in full working order will be very small.

When proposing to lay down a sewage disposal plant there need be no stereotyped rule, nearly every place will require a little different method of arrangements in detail. The difference in the composition of the sewage, the geographical position and surroundings, and the amount of depth applicable, will each need to be considered in the style of construction. The general points to be secured are, first, that when a filter is started it must be stocked with sufficient colonies of the friendly bacteria ; second, see that they are supplied at short periods with plenty of oxygen by a thorough aeration of the filter ; third, never allow the filter to empty with a rush, because in that case some of the bacteria would be washed out of the filter. Rush the sewage on as quick as you please, but draw off the effluent slowly. Never allow the filter to be water-logged longer than the microbes can exist under water on the store of oxygen that is in the air cells of the filtrate and the little there may be in the fluid. Where possible to secure carbon made by carbonizing towns' garbage, use it for a filtrate. When these instructions are adopted the plant may be made to any design and placed in any position, either open or buried underground, and the results will depend on the amount of scientific management and good workmanship introduced into the construction, as to whether 200 or up to 500 gallons of sewage per superficial yard of filter space can be run through each day.

I have already described the preparatory settling tank into which the sewage first enters for treatment after being freed of all ditritus. The bacteria filter that purifies the fluid is simply a separator, that divides the sewage into small particles, and also constitutes a residence for the millions of bacteria which are brought into contact with each particle of sewage, on which they feed and from which they extract the foul gases. Any handy material that is easily wetted and easily dried and cannot be dissolved by chemicals, will answer for the filter, because it is not so much the nature of the filtrate, as it is the size, the thickness and the arrangement of the material in the filter, that is of the first importance. The best material is that which contains the largest amount of air cells to the cubic inch, in which the oxygen can be stored when the filter is getting aerated. Carbon is preferable because it is a better non-conductor than gravel, it also possesses the most air cells and is a natural deodorizer. Thus,

either charcoal, carbon made from garbage, coal, spar, marble or gravel chips, clinkers, slag, sandstone, gravel, coarse sand, hard burnt clay or cinders will answer to charge the filter with.

If there is about 20 feet of depth between the bottom of the outfall sewer and the high-water mark of the fresh water channel into which the clear effluent is intended to be discharged, a free hand can be used in the construction of the works to the advantage of the paymasters; but if there be only five feet between the two points, a plant may still be made to work without the aid of pumps or other water lifting machinery. In places where there are combined storm-water and sewage sewers, it is unnecessary to treat sewage when a violent rainstorm is on, except that portion which is forced forward at the first rush, and which is really the scourings of the drains, because when 25 per cent. of sewage is well mixed with 75 per cent. of fresh water it becomes harmless, because the bacteria that are always in fresh water are in the ascendant, and will devour the small amount of foul matter the sewage contains. But when sewage is emptied into fresh water without being properly mixed and shaken up, it holds itself apart, and the *bacillus coli communis* and fecal microbes rapidly breed and thrive with the help of the adjoining fresh water, and resist the attacks of the scavenger bacteria by keeping in a compact body.

Filters can be constructed so that a constant current of air will flow through the body of the filtrate, simultaneously with a flow of sewage continually passing on and downward through the filtrate; and where the space is limited and room for a syptic tank cannot be secured, then in place of the dark syptic tank an upward flow roughing filter composed of crushed clinkers will answer for the preparatory process.

I have recently received the plans of a very simple and inexpensive mode of purifying sewage that is continuous in action, and requires no sieves, or screens, or any attention. If the sewage is weak because storm water gets a little mixed in, it goes through a little quicker to make up for it. It is well understood that it is the top twelve inches of a filter that does the work, and that there the bacteria slime rests because it is there where the air can be got the easiest, so the inventor forces the sewage in at one end of the filter and it moves along under the surface to the other end and passes out, thus the bacteria can secure air from the dry surface at any time.

There are a great many expensive sewage-disposal works now in use that discharge their finished effluents in a state that cannot be purged of the putrefactive matters that are held in solution, and that contain many colonies of active and dangerous microbes. These impure effluents are either discharged unfiltered, or are passed through filters which are rendered useless by the fact that they are never aerated.

For THE CANADIAN ENGINEER.

THE OXYGEN SYSTEM OF SEWAGE PURIFICATION.

BY W. M. WATSON.

The Sewage Purification Company, of Dublin, Ireland, has been good enough to send us a small pamphlet explaining their patented system of purifying town's sewage. There are several new features in the process worth noting. The company tells us that they use extra deep settling tanks, with sumps to collect the sludge, that they use baffle plates to throw down the solids, and that they supply the micro-organisms with the necessary oxygen they require by the use of nitrate of soda in place of and as a substitute for atmospheric air. They say that the oxidation of sewage is brought about by the operations of micro-organisms, and that the organisms which live on dead organic matters will quickly multiply in sewage, and will rapidly set up an oxidation of the organic matter it contains, making the sewage harmless if there is a regular and continuous supply of oxygen to all parts of the liquid under operation sufficient to sustain vitality during their life processes; and the sewage is preserved until acted upon in a neutral or slightly alkaline condition, and continued so during the activity of the organisms. When these conditions are maintained, several chemical changes take place. When the sewage passes through the first or roughing tank, the heavy solids are extracted; when passing through the second settling tank, the sewage, by the help of a precipitant, is converted into ammonia carbonic acid and water; and by the third and last process the ammonia is turned to nitric acid by microbes or bacteria. They say that they have succeeded in estimating the amount of air the microbes require to perform their work well. Thus, for very foul sewage, it takes 1,400 volumes of air to 1,000 volumes of fluid to remove the suspended matter, and even three times the bulk of air to one of fluid to finally and perfectly purify trade sewage. They point out that oxygen must be regularly supplied to the micro-organisms; if not, they will at once set up putrefaction, emitting offensive and dangerous odors. This would appear to mean that they hold that the intermittent method of aeration is a failure.

It will explain the remarks more fully by stating that the process of filtering is at present as far as sewage is concerned an artificial means of supplying the micro-organisms with oxygen. Therefore it is necessary to arrange appliances so that they will continually aerate every particle and item of the filtrate where the microbes that clean the sewage lodge. On this ground every description of filtrate must be open and porous, whether it be sand, crushed stone, clinkers, coke, fine pea coal or charcoal, and packed together in a way that will divide the sewage into small thin films that will move from one item to another on its downward passage through the filter, allowing the bacteria the filtrate contains to devour all the dead matter, also to allow a free passage of air to every particle of filtrate, so that the micro-organism it contains can be amply supplied with oxygen.

This so-called oxygen system consists of three processes, the roughing tank, then clarifying by a precipitant called manganese, often called Condy fluid, and the final process by the microbes, which are supplied with air or oxygen by the use of nitrate of soda without the help of filter beds, such as is described in the preceding paragraph, and that as thus far being in general use as a lodgment for the microbes and a medium for the circulation of air to supply them with oxygen.

The advantages of their system appear to be that by using nitrate of soda as a substitute for atmospheric air to supply the bacteria with the oxygen, they are able to sustain activity in a gradual and regular form, thus preventing any danger of the sewage setting up putrefaction during the process of purification. This, of course, assumes that oxygen can be properly supplied from nitrate of soda. The second advantage is that by using deeper tanks, baffle plates and nitrate of soda, they can keep up a rapid continuous flow through each of the three processes required, thereby purifying about 60 per cent. more sewage than can be done by other appliances used to mechanically purify foul fluids; taking only about one-third of space that other systems do for plant, having no expensive machinery pumps or fans, no tanks stand-

ing idle, aerating, etc. I approve of the idea of the deep tank and baffle plates; the soda business, also, if it is a genuine substitute for air, and can be efficiently applied at a small cost. I cannot approve the use of any precipitant, though manganese is one of the best precipitants that can be used, because the latest scientific experiments have proved that microbes and bacteria can totally destroy every impurity contained in sewage when properly aerated and housed in filters composed of powdered charcoal made from town refuse or small pea coal, and in a lesser degree by sand, small clinkers, stone and coke.

SOME MODERN FORMS OF MILLING MACHINERY.*

FREDERICK T. SNYDER, KEEWATIN, ONT.

The time has happily gone by when directors of mining companies order a mill "ready made" like a suit of clothes, and it is not unusual to have a mill designed to fit the ore it is to treat, as carefully as the development aims to explore the lead. The machinery, whose description follows, is a case where designing to meet specific conditions has been carried somewhat further than is customary. The problem was to plan a custom plant to handle the gold ores of the Lake of the Woods, many of which are low in grade, but contain streaks of high values. The absence of copper or lead in addition to the low tenor, put smelting out of the question. A site was selected at Keewatin, having ample water power with the lake for a mill pond. The ore is brought in from the mines to the plant in barges carrying thirty tons. It was decided to build the mill, to unload this ore, crush it, and sample into storage, then run over amalgamated plates and vanners; all the ore handling to be automatic. It will be seen in the following description that nothing radical was introduced, and that the principal features worth noting were improvements in the detail of existing methods.

The ore is unloaded from the barges by means of a Locke-Miller cableway of four hundred and fifty feet span. This hoists the ore in skips to an elevation of seventy feet and carries it across the main line of the Canadian Pacific Railway into the sampler building. The skip is automatically dumped into a two hundred ton bin, by means of a spring hook. The bottom of this bin is shaped like the letter W, having a gate at each point, so that each side may be used as an independent bin. Both discharge into a crusher feed hopper in the form of an iron cone, thirty inches in diameter at the bottom, placed with the open end thirty inches from the crusher feed floor. The gates being open the ore forms a cone on the floor around the bottom of the hopper, and automatically works down as it is fed into the crusher.

This crusher is of the "Invincible" type. Tension strains are carried by wrought iron, and all compression strains by cast metal. The movement of the jaw is parallel, the top and bottom moving equal distances; and not, as in the Blake, where the bottom moves more than the top; or, as in the Dodge type of crusher, where the top has the greater throw. The usual arrangement is reversed and the outside jaw made movable, with the result that the common massive frame is done away with. This brings the weight of a ten-inch by eighteen-inch machine, which is the size used in this plant, down to nine thousand pounds, while the customary weight of the cast-iron framd machine of the Dodge or Blake type is from twelve thouse and pounds to eighteen thousand pounds. Each portion of the jaw moves over an elliptical path, the long axis of which is so inclined that during the moment of crushing the hanging jaw plate moves directly towards the stationary plate, and only at the end of the stroke moves down and back to feed the material through. The result is a minimum amount of cutting of the plates by the ore, there being no sliding movement at the time of greatest pressure. The tension strains are taken by four wrought rods, which run through the frame of the machine to the rear and end in nuts. By tightening independently the rods holding the top and bottom of the hanging jaw, the inclination of the moving plate with reference to the fixed one can be altered. It is profitable to have the opening of the crusher as large as possible, that sledging may be avoided, while the angle between the jaws must be so sharp that the rock will not jump up when the jaws come together. These independent adjustments allow the angle between the jaws to be the largest practicable for any particular ore, and once placed, does not change during the operation of the crusher. In the design of this machine the parts which require attention have been concentrated at the back, so that the jaw end can be built into the feed floor, placing the jaw opening where most accessible, and at the same time bringing together within easy reach and out of the dirt and dust from the ore all oil cups and adjustments requiring attention. The inertia effects in this machine were planned to make it as free as possible from longitudinal shake, and in this plant, where it is set twenty feet or more from the ground, produce little or no vibration of the building.

The ore from this crusher is carried by bucket elevator to a screen, which deserves especial notice, its use removing the list of troubles attendant on handling crushed quartz dry through a revolving trommel. It is an ordinary gravel screen, set up at an angle of forty-five degrees, and furnished with a cover. But it is this cover that makes the difference, as it prevents the ore from taking long jumps, and thus permits the use of a screen of almost double the mesh of the product desired. That is, to get half inch mesh ore use a one inch screen, the ore particle striking the screen at so small an angl as not to fall through if more than two-thirds the size of the opening. Particles of ore which get wedged in an ordinary screen do not get into the openings of this screen at all, but jump down over it to be further crushed. The screen surface used in this plant is five feet long and ten inches wide, and readily handles six tons of ore per hour.

What fails to pass the screen goes to a pair of rolls, in which the best results of the experience of a number of mining machinery designers have been utilized. These rolls having shells thirty-six inches in diameter and ten inch face, weigh twenty-six thousand pounds, and when taking rock from a three inch screen and crushing to half inch mesh, run smoothly without jar. The frame is cast in one piece, extended below to form a hopper. The moving roll is of the sliding yoke type. The bearings are nine inches in diameter by twenty inches long, and are patterned after the journals of a railroad axle, which seems to be the best type for heavy service under repeated strain. They have a solid shell and are babbited on the side supporting the strain. The other half is chambered out to form a recess to hold waste, soaked with oil. In addition, back of the babbit is cored out a water jacket, which, in the event of heating, can be connected by hose with the water supply, and the operation of the rolls continued. The shell on the outside is but partially formed in the shape of a ball and socket box. It allows the box to adjust itself to any horizontal angularity of the shaft, such as is produced when one side of the roll is fed an the other side is empty, but prevents the

*A paper read before the Federated Mining Institute, Montreal

shell from tipping out of a horizontal plane so that the babbit in one end of the bearing cannot wear out without wearing out the other end at the same time. These bearing shells are supported in yokes, which, in the case of the movable roll, form the sliding part, and in the fixed roll are cast in the frame. By removing the caps of the yokes a roll, together with its bearings, can be lifted out at any time for repairs without disturbing the tension of the springs. One bearing of each shaft is furnished with collars on both ends, each of which, in the case of the ten-inch by thirty-six inch roll used in this plant, has a bearing surface of two hundred and sixteen square inches. Between these collars and the ends of the box are loose brass rings, making the total thrust bearing surface in each direction, on each shaft, four hundred and thirty-two square inches. These collars are threaded upon the shaft, and by screwing them in or out the shaft is adjusted endways to keep the rolls in alignment. The housing above is a prolongation of the frame furnished with openings covered with canvas curtains, making all dust tight. The shaft of the moving roll passes through sliding plates, which are held against the housing by springs. All the principal nuts on the machine are split and provided with clamp nuts, so that they can be securely held in adjustment, yet readily be loosened for movement. In operation, the rolls are set apart by means of cast-iron plates, against which the sliding box is screwed up solid. When running it does not jump. Each yoke of the sliding boxes has a bearing surface under it twenty inches wide by thirty-eight inches long, in the form of a steel plate two inches thick, removable when worn. To provide against the accidental introduction of a piece of steel too large to go through the rolls, safety springs are provided, which, however, do not yield until the pressure per lineal face of roll exceeds four thousand pounds, giving a spring pressure for this size of roll of forty thousand pounds, which will flatten out a wrought iron nut, but will allow a cold chisel to go through. The feeder for these rolls has no moving parts, but consists of a series of four inclined steps facing in opposite directions, from one to the other of which the ore slides, and is so spread evenly over the width of the roll shells. One of these steps is hinged, and by means of a short lever can be thrown up against the step above it to shut off the ore supply in case of trouble with the rolls or with the spouting above.

That portion of the ore passing through the screen goes to an automatic time sampler, which was designed for this plant. It consists of a casting about the size and shape of a miner's gold pan which is mounted to revolve on the end of a horizontal shaft. The ore to be sampled is allowed to fall on the inside of the sloping flange, and slides off into a receiving bin. At one point of the sloping flange is a narrow slot, which, as the sampler revolves, passes under the spout and allows a portion of the ore stream to pass through to the back of the sampler into a second bin, where it forms a sample of the lot. This sampler was designed to avoid the mechanical complication of the Bridgeman sampler, which was recognized as doing theoretically correct work. An attempt was also made to reduce the head room necessarily occupied by a sampler, with the result that the seven feet required for a Bridgeman sampler of the same capacity, has been reduced in this machine to twelve inches. It is probable that this machine, while making but one cut on the material, does theoretically the same work as the Bridgeman, which makes three.

From this sampler the ore drops into one of two three-ton hopper scales, where it is weighed and delivered by flat belt conveyor to one of the two hundred ton storage bins. When required for reduction it is drawn off from the bottom and carried by another belt conveyor two hundred feet into the stamp mill. These are flat belts, twenty inches wide, eight ply rubber, running at a speed of three hundred feet per minute, and have proved entirely satisfactory. The surface wears but little, the ore being given the same forward velocity as the belt, before it is allowed to drop upon it. This belt has carried over sixty tons of ore per hour on a space not over eight inches wide in its centre. The belt goes uphill and delivers the ore into the ore bins above the stamps.

From these it is fed by automatic feeders of the suspended "Challenge" type, which are without the usual frame and hopper, the disc with its rotating mechanism being hung on two iron bars at the back of the mortar. A light iron spout connects it with the ore bin gate, and the ore bin proper forms the hopper, thus giving free access both to the back of the mortars and to the mechanism of the feeder.

These deliver ore into the mortars, which were designed solely as crushing machines intended to give a maximum output when fed with ore which has passed a half-inch screen. They are double discharge, provided back and front with splash boards. The discharge from the back screen is carried through a channel cored out in the base of the mortar so as to issue, together with the discharge from the front screen, through a short spout on the front of the mortar. These mortars weigh six thousand pounds apiece, the base being ten inches thick. They are furnished with steel liners on the sides and ends, and the wear of the shoes compensated for by false bottoms of steel. The screens stand at an angle of seventeen degrees from the vertical, and are twelve inches by fifty-two inches, giving a total discharge area of twelve hundred square inches. The stamps dropping in these mortars weigh nine hundred and fifty pounds each, and drop eight inches one hundred times per minute.

The pulp passes from the mortar to the distributing box of a gyrating copper plate, four feet long and six feet wide. These are silver-plated, coated with amalgam, and by a simple mechanical arrangement each point in the surface of the plate is caused to gyrate around a circle about three-quarters of an inch in diameter. This causes each particle of ore, in place of running over a straight path of amalgamated copper six feet long, to go over a spiral path about thirty-four feet long, before it reaches the bottom of the plate. The gyrating shake enabling the table to be operated at about one half the incline necessary without it.

From these plates the tailings pass to vanners with four feet plain belts. These vanners, in place of the customary side shake of the "Frue," are given the same gyrating shake as the plates, that is, each point in the belt moves over a circular path about three-quarters of an inch in diameter. The reason for this circular shake in place of the customary side shake of the Frue vanner will be apparent to anyone who has attempted to settle the contents of a gold pan; or in a hand screen, has tried to get the coarse material on top. The advantage of this shake is so apparent, that the question arises, why it has not been used before, especially as it was patented some seventeen years ago in the United States. The difficulty has been to build a practical machine that would not shake itself to pieces under the varying strains brought about in producing this gyrating motion. Success was obtained in the vanners of this plant by stripping them of the customary heavy frame, supporting them on six round

steel rods, one end of which was screwed to the floor, the vanner resting on the upper end free to float around in any direction. The belt is stretched over rollers in the usual arrangement and below it is supported, on a short vertical shaft, an unbalanced weight. When this weight is caused to revolve by a two-inch belt the amount that it is out of balance causes the vanner to swing around in a circle, whose radius multiplied by the weight of the table equals the radius of gyration of the unbalanced weight multiplied by the amount that it is out of balance. In practice it has been found desirable to use a gyration about three-quarters of an inch in diameter, and to run the table at a speed of about two hundred and twenty-five shakes per minute. Owing to the fact that the table is just balanced by the amount the gyrator is out of balance, no jar or shake is transmitted to the floor, and no racking strain is set up in the vanner itself. The feed of the belt is obtained from a Challenge feed clutch on the head roll. The tail of this clutch is attached by a flexible link to a point on the floor, the gyration of the table furnishing the necessary movement. By changing the point of attachment of the link to the floor, the feed of the belt can be altered from nothing up to twenty-five feet per minute. The heavy frame of the Frue vanner, the side shaft with its three eccentrics, and the complicated "G" spring feed is avoided. From the vanners the tailings are divided over two more sets of gyrating copper plates, each four feet wide by six feet long supported in a similar manner on flexible steel rods, and gyrated by the revolution of an unbalanced weight supported below each.

THE D'ESTE AND SEELEY COMPANY'S STEAM TRAPS.

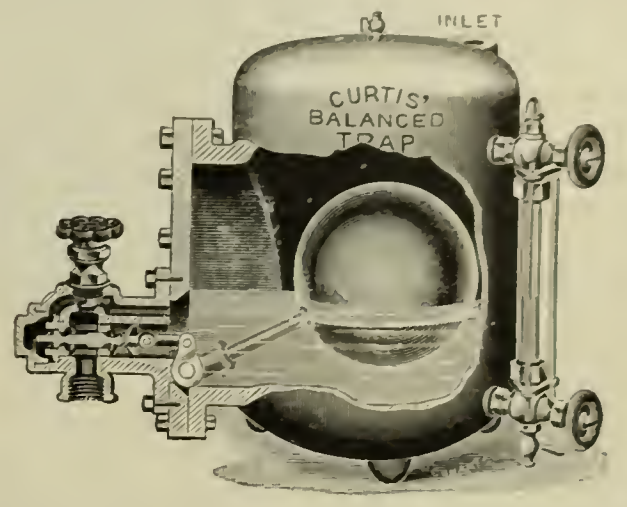
Every high pressure heating plant or any heating pipe not returning to the boiler should not be allowed to run a moment without a steam trap. No sane man would think for a moment of opening a pipe direct from his boiler to the atmosphere and try to get steam, and yet that is just what is done when a pipe is not drained by a trap. The amount of money wasted in this way on an ordinary steam plant in one season would pay for traps enough to last for years, and thus be one of the very best instruments which the owner or engineer could possibly make. While any trap is far better than no trap, it is always well to remember that a good trap costs little, if any, more than a poor one, and a purchaser with a little care in making a selection can assure himself that he is getting the best the market affords.

Four things should be required: First, efficiency; second, simplicity of parts; third, durability; and fourth, ease of making repairs when necessary. In all four of these points the Curtis balanced trap stands high, as may be seen by the following description:

The full prospective view shows a cylindrical pot with rounded ends, of the strongest form to resist pressure. On the side is a neck or nozzle of sufficient diameter to admit the float. This nozzle is covered with a strong plate, to which is bolted the composition valve. It will be seen that when the plate is removed it brings away the float and valve with it, which can be taken, altogether, to any suitable place to be examined or repaired, or can be shipped to the manufacturers, leaving the pot in place and connected.

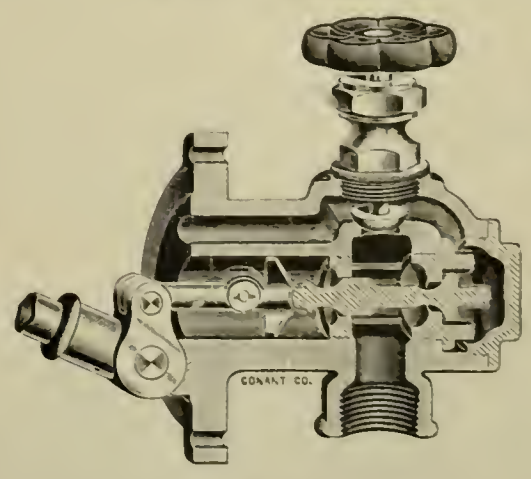
The composition valve can be removed without removing the cover, by taking out the four tap bolts by which it is fastened; then the float steam can be pulled out far enough to unscrew it from the knuckle, leaving the float inside and cover joint intact.

The sectional view shows a valve body cast with strong ears to bolt it on to the cover of the trap. The valve consists of two discs of equal area on a single stem, one with



a short sliding fit, and the other with a ground seat taper fit, which guides it onto its seat, while the valve stem is guided by a spider with three arms, and is loosely connected by a knuckle joint and stem to the float. The valve stem is in two parts, the outer one carrying the discs screwed into the inner one; and when unscrewed the valve can be taken out for repairs or grinding.

By removing the cap from the end of the valve body, the valve can be taken out without starting a joint, pipe, bolt or gasket. This is claimed by the makers as an entirely new, as it certainly is a valuable, form of construction. It is also provided with an independent passage or passby, and is the only trap, so far as known, with the valve so easily accessible from the outside. It is also provided with an independent passage or passby controlled by a stop valve, and work can be continued and the water drained off, even if the discharge valve should remain closed for any reason. The float is very large, perfectly rounded, so hard that it cannot be dented, nor can it be collapsed at 200 lbs. pressure. It is made by a special process of an alloy with aluminium, and is practically indestructible. It is hermetically sealed as a glass globe, and is so located in the trap that the outlet is always sealed by several inches of water.



These steam traps have acquired their reputation in the last eight years simply on their merits. This is presented as a strong, plain, serviceable machine, and is warranted to work correctly under any disadvantage to which a steam trap can be subjected. They will work against any head or back pressure less than the direct pressure in the trap. Some of them are now working with 75 pounds in the trap, against 30 pounds pressure on the outlet, and deliver hot water into the second and third story or into a closed tank.

The Curtis balanced trap is also often used as a water-line trap on large plants, when there is need to balance any particular circulation, to prevent snapping and cracking in the pipes and radiators. This is accomplished by connecting the direct steam-pipe to the top of the trap, and bringing in the return below the water line of the trap.

MONTREAL ISLAND BELT LINE RAILWAY.

The Montreal Island Belt Line Railway, about thirteen miles of which was opened for operation during the past year, constitutes perhaps one of the most significant facts of recent years in connection with the development of the commercial capital of Canada. At the time the North Shore Railway was being constructed between Montreal and Quebec, great pressure was brought to bear upon the Government to bring it across the Riviere des Prairies at Bout de l'Ile, and thus traverse the Montreal Island to the city of Montreal. For reasons, apparently political, this influence was disregarded, and the North Shore Railway was brought into the city via St. Martin's Junction, thus adding fifteen unnecessary miles to the length of the line. The lower part of the Island, which comprises its best half, covering a distance of about thirteen miles, consequently remained in a large measure inert, until a year ago, when operations were begun by the Belt Line. This seems to be the beginning of the much-talked-of scheme to girdle the Island, a charter for which is held by the Belt Line Company.

In 1897 the old Belt Line Company was reorganized, new blood and large capital brought into it, and operations begun on a vigorous scale. Although the charter is for the construction and operation of either a steam or electric railway, the directors judged it in the interests of the company to make use of the latest developments of electricity as a motive power. The construction of the line was pushed rapidly forward in the face of great difficulties in the way of land expropriations, and the line was opened for traffic a little more than a year ago.

The line is thoroughly constructed, on the standard gauge, and specifications of the Dominion Government railways. It has its own private right-of-way, constituting a strip of land eighty feet in width, the whole distance. It is almost a straight line from one end to the other, and with the single exception of the Canadian Pacific Railway at Hochelaga, its gradients are practically level. The line leaves the Canadian Pacific Railway at Hochelaga, and passing near the proposed Inland Basin, traverses the municipality of Maisonneuve, Longue Pointe and Pointe aux Trembles. Where the line crosses La Salle street in Maisonneuve, an extension is built along La Salle street (one of the principal streets in the town) to Notre Dame street, crossing on its way the tracks of the Montreal Street Railway at Ontario street, St. Catharine street and Notre Dame street. The Town Council of Maisonneuve, alive to its own interests, secured this concession from the Belt Line Company by granting them a perpetual franchise of the street in question and exemption from taxation for a long term of years. In its course through the municipality, the line passes close to several large manufactories, to which sidings have been laid by the company. Passing through the municipality of Longue Pointe, it runs within a few hundred feet of the immense Asylum for the Insane, which is now in course of construction.

It may not be known by everyone that the extensive Longue Pointe Asylum, which has existed for many years near the banks of the St. Lawrence in Longue Pointe for the care of an unfortunate class of the community, is about to be removed to a more suitable location, about a mile and a half further back on the same property, where the buildings will be reconstructed on an immensely larger scale than ever existed before, and that to this end the Quebec Government guaranteed a loan of $500,000 at a low rate of interest. The buildings of the new asylum are in the course of construction, and when completed will constitute almost a town of themselves.

From Longue Pointe the line of railway pursues a perfectly straight course to Pointe aux Trembles, a most flourishing and attractive suburban village, situated about six miles from Montreal. Since the advent of the railway building, operations in the village have been very active, and there is every prospect of a most prosperous time for the village. From Pointe aux Trembles the line turns slightly to the left, and following the course of the St. Lawrence River, and in full view of it, it reaches Bout de l'Ile, a distance of another six miles, passing on its way the Catholic convent at Pointe aux Trembles, and the French Protestant Training School.

A Straight Bit of Track.

At Bout de l'Ile, where the cars are connected by a steam ferry with the town of Charlemagne and other points, a large park has been established by the company, covering more than twenty-five acres. Bout de l'Ile ("the end of the Island") is an ancient hamlet, beautifully situated at the "meeting of the waters," where the Ottawa (Riviere des Prairies), merges into the blue St. Lawrence. The company has transformed this dreamy hamlet into an ideal summer resort. Its charming grove of maples and elms has been turned into a picnic ground, and ample pavilions, band stand, boat-houses and bath-house put up. A bicycle track has also been laid out around the park, to form at no distant date an important feature in the plans of devotees of the wheel in Montreal. The large hotel overlooking the two rivers has just been purchased by the company, and plans have been made for a big extension, which is to be ready for occupation by the Queen's birthday. The idea is to provide first-class accommodation and harmless and amusing diversions for the citizens. The hotel grounds will comprise 330,000 sq. ft. of land, and the new building will have a dining-room 36x60 ft., and a billiard-room 20x50 ft. The grounds will have fountains, tennis lawns and croquet courts. That the susceptibilities of temperance people may not be offended, the bar will be kept away from the hotel building altogether.

The company, in equipping their line, made a new departure from what has seemed to be the established custom in Montreal. The cars placed upon the road are of the best description, finished inside and out of imported mahogany, oiled and polished. The cars, instead of being the orthodox one-truck, were equipped each with double Taylor electric trucks of the latest construction. Inside they are luxuriously upholstered and polished, while the unsightly stoves of some electric railways have vanished, and each car is heated with six electric heaters of the latest description. They are handsomely vestibuled at both ends, and brilliantly lighted. These cars can only be compared to Pullman coaches on a smaller scale. The open cars, so much appreciated by summer travelers, are likewise built and finished in the handsomest possible manner. They are forty-five feet long, also double trucked with the Taylor Electric trucks. One of the open 45-ft. cars is shown in the accompanying engraving.

The company has also placed upon its line an electric locomotive, built to handle ten loaded cars. This latter move was made in order to meet the demands of the trade in the lower part of the city, connections having been made with the tracks of the Canadian Pacific Railway. A satisfactory arrangement was made with the latter company and the Belt Line for switching the East End freight coming over the Canadian Pacific Railway and destined for points in Maisonneuve, Longue Pointe and Pointe aux Trembles, and the end of the Island, in car lots.

An electric rotary plow has been in operation all the winter, and has performed most efficient work. The snowfall of the past winter is well known to have been one of the most severe in the memory of man, and on the occasion of the most severe

of these storms, when all the steam railways in the country were tied up for three, four and five days at a time, the rotary plow of the Belt Line opened the line up from one end to the other inside of five hours. At places the drifts of snow were so deep that the upper part of the drift had to be removed to permit of the egress of snow from the machine as it was discharged in a continuous and rapid stream from the vents.

Double Truck Car.

The power-house of the company is built about half way between the two ends of the line, near the village of Pointe aux Trembles. It is situated on the edge of the St. Lawrence, and a wharf has been built at this point out into the stream. Two large car barns have also been erected, besides other minor buildings, and as this point is connected with the main line by a short branch of a few hundred feet, there appear to be excellent

Rotary Snow Plow.

facilities for ultimately bringing car-lot freight from Montreal, destined for shipment, and here transferring to the vessels. The company before deciding upon its equipment investigated all the latest improvements in electricity, and canvassed the various electric manufacturers in Canada and the United States. The decision arrived at, and what has been carried into effect, was to install three compound condensing Wheelock engines, aggregating over seven hundred horse power, belt connection, and two electric dynamos, one of 200 kilowat, and the other of 325 kilowat. The contract for the engines was given to the well-

A View in the Park.

known makers, Goldie & McCulloch, of Galt, Ont., and was carried out in a highly satisfactory manner to the railway company. The engines are models of perfection, grace and easy working. They are placed on massive masonry foundations, and when revolving at a high rate of speed, so slight is the vibration that a copper cent can be set upright on its edge on the curved surface of the cylinders and remain there indefinitely without being overturned. The engines are divided into three units, two of 150 h.p., and one of 435 h.p. By thus dividing the units, the power for every varying condition of traffic upon the company's line is made to correspond with the consumption of fuel. So economically are these engines built and graduated that during last year's operations the consumption of fuel, repairs to motors, engines, boilers and generators, all included, amounted to less than 2 1-3 cents per car mile. The makers appear to have surpassed their usual excellence of work. The contract for the large electric dynamos was given to the Canadian General Electric Company, of Peterboro, and has been filled in an equally satisfactory manner. These machines will develop as high as 900 h.p. between them, and their regular rated capacity is nearly 700 h.p. At times during the past summer work upon the line was very heavy indeed, notwithstanding which no defect of any kind discovered itself in these magnificent machines. The motors for running the cars were also obtained from the Canadian General Electric Company, and were placed two to a car. They average about 35 h.p. each, and are geared to run the cars at a speed of about 25 miles an hour. The motors have done excellent service. Twice since the opening of the line for operation, the company have been obliged to increase the number of cars and motors.

The car bodies were built principally by the Ottawa Car Company, of Ottawa, and the managers believe that in construction and finish they are unsurpassed by any electric cars in Canada. The number of cars now consists of four large open cars, 45 or 50 feet in length, and with a capacity of 150 to 200 people to the car; five shorter cars, and four closed cars, in addition to the locomotive. Several of these cars have been added quite recently, as the traffic during last season was so great as to frequently compel passengers to satisfy themselves wih standing room only. It is with a view of doing away with this inconvenience to their patrons that the company has lately increased its rolling stock. During the year past, which was the first year of opening, the company handled over 300,000 people, and it is anticipated that during the present year this number will be doubled.

The operating expenses of the road were only 62 per cent. of the gross receipts, notwithstanding the fact that much experience had to be learned, and that last season was unprecedently wet and cold. During the summer months the cars ran every ten minutes, and throughout the winter an hourly service was maintained. The operations of the company so far have given

The Old Horse Ferry.

such satisfaction to the public, as to support the belief among some railroad officials, at least, that it is best to conciliate and please the patrons of the road. Incredible as it may seem to outsiders, before this railway was opened, the lower part of the Island was in a worse position as regards postal facilities and

traveling accommodations for the public than many country districts a hundred miles away. The only means of communication was the old-fashioned stage coach, which ran daily between Montreal and Bout de l'Ile, plodding its weary way through mud or snow drifts, as the case might be, exposing its patrons to a drenching rain or a burning sun, and consuming from three to six hours in making the trip. The evening newspapers' issues to-day did not reach their subscribers until to-morrow night, notwithstanding that these seekers after knowledge were within twelve miles of the metropolis of the country. The communication with Charlemagne and the towns along the line, some of them of very considerable importance, including the large town of l'Assomption, at which there is one of the most noted educational institutions in the country, was restricted until lately to a peculiar construction called the "horse-boat." This craft was composed of two hulls placed side by side, and planked over, a stern wheel is slowly revolved by means of a pair of unhappy-looking horses working a tread-mill. The approach of the boat to either side was irregular, and usually depended upon the impulse of the officials in charge. There was not, however, usually any chance of the waiting traveler losing his boat, as its approach was heralded from afar by the clanging and rumbling of the iron cogs of the wheel connecting the tread-mill with the unhappy horses at the back. In stormy or windy weather the boat usually declined to make any trip at all. One of those quaint craft is still to be seen at Bout de l'Ile. It is probably the most primitive form of ferry-boat to be found on this continent. J. H. Bernard, of Montreal, informed a representative of THE CANADIAN ENGINEER that his grandfather used to cross the St. Lawrence by this ferry over 100 years ago, and it was doubtless in use long before his day.

Some time, no doubt, the railway will be extended across the river. Sixty years ago an enterprising farmer on the other side of the river constructed a bridge at this point over both channels of the Riviere des Prairies, aggregating about half a mile or more in length. The model of this old structure is still to be seen in the old dwelling-house of the time. It is an ingenious construction, and bespeaks a great degree of industry and no little ability in the maker. This useful structure, however (for during its life it was used by a great many people), was not long for this world. Some three years after its construction the high water of the spring and the ice carried it mercilessly away, and nothing remains to tell the tale beyond the approach on each side, and here and there the ruins of a sunken pier.

Since the opening of the railway the aspect of everything has been changed. The beautiful farm sites along the banks of the river have been laid out in building lots, and many cottages have been erected. Four rivers, known as the l'Assomption River, Back River, and Riviere des Prairies, the two latter being branches of the Ottawa, and the mighty St. Lawrence, all come together at Bout de l'Ile, hence this point has been fittingly named "Where the Waters Meet."

ROBERT WELSFORD, ENGINEER.

The Belt Line cars are always on time at the intersection of La Salle street and Notre Dame street, in Maisonneuve. One of the strict rules of the company is that the cars run absolutely on time. The point of starting is reached by the Notre Dame street line of the Montreal Street Railway. During the winter the Ontario street line of the latter company has been extended to the intersection of the Belt Line, and during the coming season Montrealers will doubtless find it both pleasanter and easier to reach the Belt Line cars without the trouble of making any transfer on the way. By this means a passenger can take the Montreal street car at Wellington street, and for four cents enjoy a trip of nearly seven miles in length, where he again proceeds another twelve miles to a charming park at the end of the island, and which is so large that even when four or five thousand people are scattered over it, there can be found a quiet retired corner for himself and his picnic surroundings.

The officials of the company are W. Dale Harris, late managing director of the Ottawa and Gatineau Railway Company; John P. Mullarkey, managing director, a railway man of considerable experience; John Rowley, superintendent; Robert Welsford, engineer in charge of engines and plant, and C. H. Wright, electrician.

Robert Welsford, engineer of the Montreal Island Belt Line

W. DALE HARRIS, PRESIDENT.

Railway, was born in Paisley, Ont., 35 years ago. As a boy he obtained his education under great difficulties, having been able to go to school only two years, but while serving his apprenticeship as a miller, he studied at night, and made good headway in his studies. He filled good situations as miller with such firms as A. W. Ogilvie & Co., Montreal; James Goldie, Guelph, and Robert Noble, of Norval. Owing to fail-

J. P. MULLARKEY, GEN. MANAGER.

ing health, he quitted the milling business, and afterwards, having a taste for engineering, he took instructions in mechanical and electrical work for one week, and with this short appren-

tieship he installed the first arc light plant in Mount Forest, ten years ago. Since then he has been steadily employed as an engineer. Mr. Welsford's aim is to produce horse-power with as little fuel and friction as possible, and in aiming at this he has never been in want of a situation, while at the same time he has been able to help more than one fellow engineer in time of need. Mr. Welsford is the inventor of a new oil filter and waste sewer, which has been in use for five months at the Montreal Island Belt Line power house, with the most satisfactory results. We hope to give a description of this device in an early issue.

W. D. Harris, president, and J. P. Mullarkey, managing director of the Montreal Island Belt Line Railway, were associated on the directorate of Pontiac and Pacific Junction and the Ottawa and Gatineau Railways. Mr. Mullarkey was first connected with the Belt Line Railway as managing director, which position he held for about a year, when he purchased the capital stock, reorganized the company, and induced Mr. Harris to become president.

JOHN ROWLEY, SUPERINTENDENT.

John Rowley, superintendent of the Montreal Island Belt Line Railway, is an old steam railroader, having been connected with the Midland Railway, Quebec Central, Quebec & Lake St. John Railway, Ottawa & Gatineau Valley, Pontiac & Pacific Junction Railway. He also put in the large new main water pipe from Lorette to Quebec city, eight miles, for the supply of water to the city, bridging the St. Charles with a tubular bridge. The stop gates and all connections to that system were done under his supervision. He took charge of construction on June 1st, 1896, of the Montreal Island Belt Line, and charge of the operating department Nov. 1st, same year. Born in the city of Quebec, 1861, went through the common school and took commercial course through the High school, Quebec, under the noted principal, Daniel Wilkie.

C. H. WRIGHT, ELECTRICIAN.

C. H. Wright, the Montreal Belt Line Company's electrician, started with the Renfrew Electric Company as trimmer and cleaner. He then engaged with the old Royal Electric Co., of Montreal, as dynamo tender in the alternating and power station, and later as wireman. He subsequently joined the Edison General on installation work. Returning to Renfrew, he installed and operated a three-wire alternating plant, it being the first of the kind in Canada. Leaving there, he worked at Peterborough for the Canadian General Co., then for the Kingston Street Railway, and finally constructed the Belleville Street Railway line. In 1892 Mr. Wright entered McGill University, from which he was graduated as B.A. Sc. in 1896, taking honors and leading in all electrical subjects of the third year. In the fourth year he led the electrical engineering graduating class, taking honors in four subjects, and making all the marks obtainable in electrical laboratory work under Prof. Callendar. Mr. Wright was vice-president of his class. He entered the employ of the Belt Line when the first rail was laid, and when operation started he was taken into the permanent staff as electrician.

ACETYLENE GAS ON A CANADIAN RAILWAY.

The Pontiac Pacific Junction Railway Co. claim the credit of having the first express train in America, if not in the world, illuminated with acetylene gas. In conversation with Andrew Holland, of Ottawa, Wm. Ressman, superintendent of the road, suggested that acetylene gas would be a splendid illuminant for railway trains, if it could be safely handled. Mr. Holland expressed his firm conviction that it could be done with a Niagara Falls generator, if space in the baggage car were devoted to the purpose. Mr. Ressman at once placed two cars at Mr. Holland's disposal for the experiment. A twenty-light generator was installed in the baggage car. The cars were regularly piped for gas, with ordinary goose-neck drop fixtures. At each end of the cars the main pipe, ⅜, terminated with a hose cock, by which means the gas was piped between cars by rubber tubing. It was a hard time of the year for such a test, coming on the severe frost and storms of January. It was, however, a splendid success, so far as illumination was concerned. The light was as steady as starlight, bright and soft, so that passengers on the train could read the evening papers from any seat in the car with ease. The frost had no effect on the gas, and no amount of shunting could put out the lights. The disadvantages were: 1st, space occupied by the generator: 2nd, slopping over of the gas tank; 3rd, danger of causing slop and smell, should an explosion take place, where such a quantity of gas had to be generated, and trainmen with lanterns, pipes and matches always present; 4th, the putting out of the lights in the other cars when the baggage car had to be disconnected.

Mr. Ressman said if these difficulties could be overcome, acetylene gas, as an illuminant, had come to stay. It was cheap and effective. An idea suggested itself to Mr. Holland, that if small generators were coupled up in series to a main feed pipe, individual car lightning could be effected without any of the drawbacks complained of. The piping of the first-class car was slightly changed, five small generators, each 18 inches high, and 10 wide, were installed on shelves in a locker in the water closet. Mr. Holland felt confident that he had solved the problem. The first trip was a disheartening failure. When the train got up speed and the car began to rise and fall on its springs, out go the lights, and it took a box of matches to keep them re-lit. By the next trip, Mr. Holland had thought out a simple plan to remedy this defect, and the cars are now running with the lights in perfect order. Mr. Ressman has, in consequence, decided to equip both systems of railway, over which he has the management, with acetylene gas fixtures.

Mr. Holland's next experiment was with a locomotive headlight. The management of the Canada Atlantic Railway, ever alive to the improvement of their line, and the comfort, convenience, and safety of their patrons, placed a shunter engine at his disposal. The experiment proved the possibilities of acetylene gas as a headlight illuminant. Locomotive No. 26, of the Montreal express, was then temporarily piped ; for the headlight and gauge lamp, the postal baggage and express car were fitted up, and on Monday evening the express pulled out with the new light. Mr. Holland rode with the engineer, feeling anxious about the result, as the installation had to be put in so rapidly. The headlight was splendid, lighting up the entire right-of-way and far away ahead of the train. The terrific vibration of the locomotive did not affect it, but coming round a curve, a sharp rush of wind down the lantern ventilator extinguished the headlight, while the gauge lamp light, unprotected, was also blown out. The train was slowed down while the fireman went forward, re-lighted the jet, stopped the hole in the lantern with cotton waste, and the train proceeded without any further trouble. The postal car was so brilliantly illuminated that the clerks told Mr. Holland he would have to come with a revolver in both hands to take out his plant again. It is claimed that the system adopted by Mr. Holland is at present the only safe

way known to utilize acetylene gas where the generator is subject to vibration and is liable to come in contact with fire by accident or design. He deliberately explodes a generator without doing any more damage than causing a report like that of a toy pistol. The safety lies in the fact that only a very small quantity of gas is generated at one time. Railway men are taking a deep interest in the new light. Mr. Bailey, of the Railroad *Gazette*, of New York, came to Ottawa specially to investigate the system, and after seeing the generator charged and the train lighted, declared it to be the most simple and effective light for railways that he had ever investigated. The Government car "Cumberland" has been piped for gas and a plant installed. Mr. Schreiber is anxious to have the gas system thoroughly tested as to safety, as well as efficiency. It will be of interest to railway engineers to know that the locomotive headlight generator makes the run from Ottawa to Montreal on two pounds of carbide, costing three cents per lb. wholesale.

THE YORK STREET BRIDGE, TORONTO.*

This bridge is at the foot of York street, Toronto, and gives access to the water front from the city for vehicles and pedestrians over the numerous railway tracks at that point As the bridge was built jointly by the city and the Canadian Pacific Railway, the plans were prepared by P. A. Peterson, chief engineer of the C.P.R. and approved by the City Engineer of Toronto.

The general design of the bridge is a steel trestle, composed of about 32 spans deck plate girder, ranging from 30 feet to 70 feet span, with wooden stringers and decks. There are also in addition two spans of less than 20 feet, rolled steel I beams. These girders and I beams rest on iron columns, standing on stone pedestals, except at the three ends of the bridge, where there are stone abutments. The width of the roadway, except on the southerly ramps, is 37 feet 6 inches, with sidewalks on each side 7 ft. 6 in. wide. On the southerly ramps the width of roadway is 32 feet 6 inches, with one 7 ft. 6 in. sidewalk. The ground plan of the bridge is "T-shaped," with the base resting on the south side of Front street, and it extends southerly therefrom, across the deviation of York street and the railway tracks to Lake street, a distance of about 906 feet. Here the ramps of the bridge turn, one to the right, and the other to the left, and descend to the level of the street. The length of these ramps is each about 316 feet, making a total length of bridge of 1,538 feet. From Front street the roadway of the bridge rises with a grade of one foot in twenty, for about 298 feet, and at the Lake street ends, there are similar falling grades of one in twenty, about 500 feet in length. Heavy loads to the railway freight sheds are taken over these grades every day, and no special difficulty seems to be experienced. There are in all three abutments and sixty-eight pedestal blocks. The foundations of the two Lake street abutments and all the pedestal blocks, except fourteen north of the south line of the old Esplanade, are on piles driven to the ledge rock. This was necessary, as this land was formerly part of Toronto harbor, and had only been filled in the year previously with miscellaneous rubbish, earth, brickbats, tin cans, as well as more objectionable refuse. When piles were to be driven, an excavation was carried down to one foot below zero level of the water of Toronto harbor, and soundings were then taken down to the rock. The piles were then cut off the correct length and driven home, with a "follower." Under the specifications, the piles were to be cut off one foot below zero level, and the above method was found less expensive than actually cutting them under water, and it was very seldom that a pile had to be cut when once driven home. Only a very blunt point was made on the pile, before driving. Four piles were driven for the small pedestals, eight for the medium and nine for the large pedestals. Under the abutments the piles were 4 ft. centres longitudinally, and 2 ft. 6 in. transversely. The excavation was then carried down six inches below the top of the pile and two feet in depth of concrete put in. In some cases where the underlying material was very soft, short lengths of two-inch plank were laid flat under the concrete, between the piles, in order to keep the concrete from settling on the soft material before it was set. The concrete foundation is 7 feet square under ten of the pedestals carrying the longer spans, 6 feet square under nine of the pedestals, 5 ft. 6 in. square under five pedestals, and 4 ft. 6 in. square under the remaining 44, and is generally two feet deep. The concrete was composed as follows, except when laid under water: Cement, 1 part, clean sharp sand, 3 parts, broken stone, 5 parts—all by measure. Under water the concrete was composed: Cement, 1 part, sand, 2 parts, broken stone, 5 parts. The cement used was the "Star" brand, made by the Rathbun Company, of Deseronto. Below ground the stonework is what is known as "rubble masonry:" above ground it is "rock-faced ashlar," and was built under the Canadian Pacific standard masonry specifications. The stone was brought partly from the contractor's quarries at Owen Sound, and partly from the Orangeville quarry. The contractor for concrete and masonry work was David Chalmers, of Owen Sound. The piling was done by the railway company's own men, and their track pile driver. The two top courses of the pedestals had to be drilled before being placed in position to receive the 1¼-inch iron rods which secured the iron columns to the masonry, and some little difficulty was experienced drilling completely through these stones without breaking them. This drilling was done with a steam drill, half from each side of the stone. The iron work was erected during the winter of 1896-7. It was supplied and erected by the Central Bridge and Engineering Co., of Peterboro', Ontario, and was paid for at so much per lb. in the finished work. The bridge was designed to carry in addition to its own weight the following live loads, either singly or in any combination: (a) 100 lbs. per sq. feet of roadway and sidewalk, (b) one 32,000 lb. road roller having a wheel base of 11 ft. 2 in. in length and 7 ft. 4 in. transversely, (c) a string of electric cars 26 ft. long, each weighing 30,000 lbs., fully loaded, on each track.

All parts of the structure were proportioned so that maximum loads should produce no greater tensile strain upon the net section than 12,000 lbs. per sq. inch. A wind strain of 400 lbs. for each longitudinal lineal foot, and 150 lbs. for each vertical lineal foot of the trestle bents was allowed for.

All steel had to come up to the following requirements:

Ultimate strength	58,000 to 65,000 lbs.
Elastic limit	33,000 lbs.
Elongation in 8 inches	20 p.c.
Reduction of area	40 p.c.

and was made by the open hearth process. Before leaving the shop it was thoroughly cleaned of all loose scales and rust with steel scrapers and brushes, and was then given a good coating of red lead mixed with linseed oil, well worked into all joints and surfaces, and after erection the ironwork was given two more coats of paint. All the timber in the deck of the bridge, with the exception of the sidewalk planks and paving blocks, is southern yellow pine, creosoted with 10 lbs. of dead oil of coal tar per cubic foot.

On top of the joists and 4-inch plank, were laid two thicknesses of best tarred paper, thoroughly sealed with roofing pitch to the planking, and each other. On top of this was laid the paving blocks, consisting of square-cut white pine blocks, 8 in. x 4 in. x 4½ in. deep, grain upwards. These blocks were held apart at the cross-joints by three specially-made nails driven into each block up to the collar, leaving the blocks 3-16 in. apart. All joints and vacancies were then filled in with best paving pitch, and the roadway covered ½ inch deep with gravel. A double track girder rail for electric cars was laid across the bridge by the Street Railway Company before the paving was done, for possible use in the future. The sidewalk planks are of tamarack, 7 ft. 6 in. long, 2 in. thick, laid with 1½-in. felt towards the kerb. The cost of the structure was approximately:

Foundation and earthwork (including piling)	$ 4,200 00
Stone and concrete work	15,900 00
Ironwork	43,000 00
Damages St. James' hotel property	4,900 00
Deck and roadways	28,000 00
Engineering	2,000 00
	$98,000 00

* Extracted from a paper read before the Ontario Land Surveyors, by A. P. Walker, of the City Engineers Staff, Toronto.

ONTARIO LAND SURVEYORS.

The adjourned annual meeting of the Ontario Land Surveyors was held March the 8th in the repository of the association, in the Parliament Buildings, Toronto, the president, T. H. Jones, of Brantford, being in the chair. On this, and the two succeeding days, the meeting was occupied in hearing the reports of the various committees, and in listening to the reading of a number of very valuable papers by different members.

Extracts from some of these papers will be given our readers next month, as lack of space prevents us giving a full report of the meeting in this issue. The annual dinner took place on the evening of the 9th, and was a most enjoyable affair, being more largely attended than any previous dinner. The nominations of officers resulted as follows: President, P. S Gibson, elected by acclamation; Vice-President, H. J. Bowman, elected by acclamation; Secretary-Treasurer, A. J. Van Nostrand, elected by acclamation. For Council of Management, in place of F. L. Foster and J. L. Morris, whose terms expired 1st of April, four candidates, F. L. Foster, J. L. Morris, Geo. Ross and Capt. W. F. Van Buskirk, were nominated. For auditors, A. W. Campbell and H. L. Esten, by acclamation. The president appointed as scrutineers of ballots Capt. K. Gamble and J. F. Whitson, who will, on the 7th of April attend the opening of the ballots by the secretary.

STEEL CYLINDER PIERS.

Editor CANADIAN ENGINEER :

In the item in last issue of THE CANADIAN ENGINEER *re* bridge recently completed at Dundas, Ont., you say it is supported by steel "rail" piers. This should be steel "cylinder" piers. This is a small error, but I would not like anyone to think I would construct a pier of steel rails.

Yours very truly,

JNO. S. FIELDING, C.E.

Hamilton, March 12, 1898.

MINING IN QUEBEC.*

BY J. OBALSKI, G.M E

The state of the mining industry in the Province of Quebec during 1897, is shown by the following notes, and is quite satisfactory, although there is no booming, for the present, on any of our minerals. I would mention copper and asbestos mining, charcoal iron-making as very important industries, with mica and chrome coming after, besides a few others which may become prominent later on.

IRON.

The Radnor forges had its furnace in operation for the whole year, and the Drummondville, one since July. They have produced 8,386 gross tons of pig iron, 680 men being employed by this industry. The consumption of raw material has been 19,766 gross tons of bog ore, 2,545 gross tons of limestone, 1,031,800 bushels of charcoal. The quality of the product need not be mentioned. It is a credit to our country: in fact, it is highly praised, not only in Canada, but in the United States and Europe, competing with the best brands on either of the continents.

CHROME.

This year, shipment has been 2,340 gross tons, mainly to the United States, and we have still in hand over 2,000 tons, about 60 men being employed. Our ore is mostly high grade, but I consider that with concentrating plants, we could use our low grade ore and the refuse of the mines, and considerably increase our shipments. This industry is in its infancy, but nevertheless, with only hand-working, we have taken out, since 1894, over 10,000 tons, representing an approximate value of $140,000, of which 8,183 have been shipped. I refer to a pamphlet I am just publishing on the subject.

TITANIC IRON.

I would make mention of the discovery of important deposits in the Lake St. John district. People have also an eye on our magnetic sand, on the north shore, which may eventually become profitable to handle.

OCHRE

Is prepared as in the past by two companies, in the vicinity of Three Rivers, with a production of 1,239 short tons of burnt ochre, which have been used in Canada, or shipped to the United States, 50 men being employed.

COPPER.

Our low grade ores have been worked as usual, at Capelton, the product being 36,815 gross tons, of which 29,512 tons were shipped to the United States, a small cargo to England, and the balance used on the spot for sulphuric acid manufacturing, 270 men being employed. At Harvey Hill, some work has been done, but only 20 tons of high grade ore shipped. Several prospects have been made at a few points of the Eastern Townships, and the time may come when this industry will be one of the most important of this province, if we take into consideration the numerous good mines actually idle

LEAD, ZINC AND SILVER

On the Calumet Island several good prospects have been made, showing the existence of an important mineral belt, containing zinc blend, and rich galena, carrying sometimes 200 ounces of silver to the ton. The Lake Temiscaming mine has also been worked to some extent, but no shipments made, and we may say that last year's output has been 450 tons of zinc blend, and 5,000 tons of galena, 45 men being employed

GOLD.

Prospecting was going on in the Beauce district, on the Gilbert, on the du Loup, and in Dudswell district, with also some finds reported in the vicinity of Sherbrooke Besides those we know of, every summer, small parties find their living by washing in the rivers of our gold district Some preparatory work has been done last fall on the old diggings of the Gilbert River, and according to recent informations, gold, in paying quantity, has been struck. I estimate approximately, that not more than $900 of gold have been taken out during the year. The question of the Beauce district has been discussed at length at previous meetings, and although not yet satisfactorily settled I personally am fully confident in the final success of that region.

GRAPHITE.

The graphite industry is one of the most difficult to operate advantageously in Canada, as we have to compete with old establishments in the United States, taking easily their supply from Ceylon. In the Buckingham district we have three companies with well equipped mills, two using the wet, and one the dry process, and it appears to me that their product is as good as any other one, and all that we require is a regular market for it. But little work was done last year, and we have not the account of the production.

ASBESTOS.

The market for asbestos has been fair: three companies at Thetford, and one at Danville, employing altogether 800 men, have been in operation for the whole year, having shipped 12,565 tons of 2,000 lbs., of fiber, about 42,000 gross tons of the new product, called asbestic, have also been prepared, of which a very large quantity has been shipped, and the contracts made for the coming year will, it is expected by the company, take the entire output. Shipments have been made to England, Germany, Australia, South Africa, besides the United States and Canada. The Black Lake mines have not been in operation this year, and the production of two companies, having their mill in the Laurentian district, near Ottawa, was small, little work being done.

PHOSPHATE.

No work done on this material, except a few hundred tons extracted from the mica mines.

MICA.

Several prospects were made in the Gatineau district, but of small importance. In the vicinity of Perkins mill, in Templeton, three important companies have worked regularly, and taken out a large quantity of mica, well adapted for electrical purposes, of which a good part has been sold in Canada, and in the United States. It is very difficult to give exact figures regarding this mineral, on account of the numerous qualities and sizes, representing as many different prices, but according to the best informations, I estimate that about 200 short tons of thumb-trimmed mica have been taken out, 90 men being employed. I understand that the demand is less than previously, on account of the high duty in the United States, and that only the best grade of electrical mica is wanted. No mine of white mica has been worked last summer.

PETROLEUM.

Prospecting and boring are going on as usual in the vicinity of Gaspe. Last season, some excitement prevailed on account of a larger quantity of oil being struck in one of the wells, which, in fact, has been flowing for some time. Nevertheless, nothing very definite has yet been ascertained. About 30 wells have been bored, some of them having struck oil in greater or less quantity. I am confident in the future of this district as an oil-bearing one, but the country is large, and its stratigraphi-

*A Paper read before the Federated Canadian Mining Institute.

cal structure not very well known. We don't know that any shipment of oil has been made, so far, except some barrels as specimens, and. in fact, there is not yet regular pumping done.

FELDSPAR.

In the vicinity of East Templeton Station, a quarry of feldspar has been worked with 15 men, for the whole season, the quantity shipped being 1,260 short tons. The material appears to be of a good quality, and is sent to the United States for ceramic purposes. A few other deposits of them, connected with white mica mines, exist, but are not worked.

KAOLIN.

I want to make a special mention of the discovery of this material in our province. In 1894 I visited the township of Amherst, Labelle county, and my attention was called to a white material, which, after testing, I was able to pronounce to be a genuine kaolin. The indication was a small one, but may lead to the discovery of an extensive field of said material. Subsequently R. Lanigan, from Calumet, secured some property there, made some prospects, and came to the conclusion that workable deposits existed. He also sent specimens to porcelain works, and received high testimony regarding the quality. The Imperial Porcelain works, of Trenton, U.S., have pronounced it of a superior quality. The district above-mentioned is five miles from the Montfort Railroad, which connects with the C.P.R.

MOLYBDENITE.

We have enquiries from a party in England about this mineral, which I understand has some new use in a form of alloys, but the price offered (14 cents per lb.), does not give much chance for the opening of our small deposits, which, besides not being developed, are rather far from ordinary communication, we know of only three deposits giving indications of some importance, one on the north shore of the St. Lawrence, and the other in the Gatineau valley. The latter was discovered in Egan township, about 110 miles from Ottawa; the surface indications would justify further development.

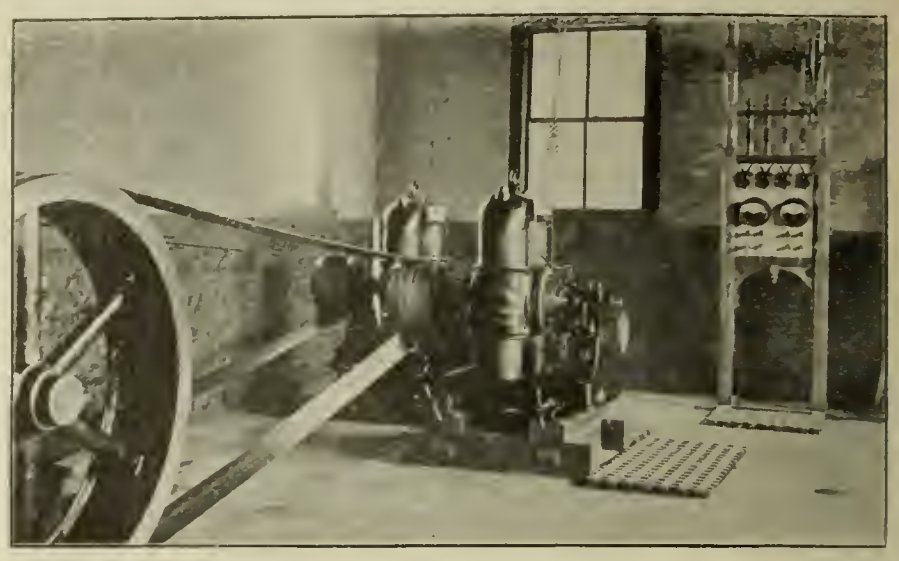
BUILDING MATERIAL.

There is nothing special to mention in this line. We have shipped 3,208 tons of 2,000 lbs. of slate, 90 men being employed, and also 1,072 tons of flag-stones. I am not prepared to give any figure on the building stones, notwithstanding its importance. Re granite, the Stanstead, Whitton and Lake St. John quarries have been in operation, as usual, the latter only for local supply. The limestone quarries, on the Trenton belt, between Quebec and Ottawa, have been extensively worked. We record, for 1897, a production of 14,000 barrels of cement, but new companies are in process of formation, and preparations are made to considerably increase it for the coming year. If we consider the large consumption of such material, in our country, which is partly supplied by an importation of over 200,000 barrels, we may look for a good future for this industry. The established lime kilns and brick-yards are going on as usual. It is not easy to give exact figures regarding the same, as they are scattered all through the province, but by careful researches, I am able to give the following: Approximately, we have, in round numbers, 300 lime kilns, producing one million of bushels of lime, of a value of $140,000, with 250 men employed all the year round. In round numbers also, we count 150 brick-yards, employing 1,200 men for the summer season, and producing 120 millions of bricks, of a value of $600,000.

As a conclusion, I may say that the raw value at the mine of the minerals taken out from this province, represents about $1,800,000, including the building material, the number of men employed the most part of the year being about 4,000.

CHATHAM MUNICIPAL PLANT.

The electrical equipment of the municipal arc lighting plant installed by the city of Chatham, Ont., last fall, consists of two automatic arc dynamos of nominally 50 lamps capacity each. These are supplying current to 104 arc lamps and 10 series incandescents, through circuits which aggregate some 24 miles in length. The 10 incandescent lamps and two arc lamps are used for illuminating the power-house and adjoining waterworks plant, while 102 lamps are for street illumination exclusively. These latter are provided with substantial telescoping storm protectors, and are suspended from a suitable steel mast arm. Sleet-proof lamp supporting pulleys and thoroughly insulated lamp hangers are used throughout. The outside circuit is of No. 6 B. & S. hard drawn copper wire, triple braided, strung over double petticoat insulators, and at intervals of two



POWER HOUSE—CHATHAM MUNICIPAL PLANT.

miles is protected by an effective magnetic blow-out lightning arrester. Wherever possible, the circuit is divided into loops, comprising some five to ten lamps, each loop being controlled from a substantial absolute cut-off switch.

The interior wiring is of No. 6 B. & S. rubber-covered wire. A plug switch-board, arranged so that machines and circuits may be interconnected, is provided. This is furnished with ammeters and magnetic blow-out lightning arresters of a new pattern, the whole being neatly arranged on a white marble base. The whole plant was subjected to the most vigorous tests which would ever meet the demands of service. The machines were short circuited at full load for one minute, and also while at full load the circuits were suddenly opened. These tests thoroughly demonstrated their ability to withstand any exigencies of service. This was manufactured and installed by the Thompson Electric Company, then of Hamilton, but now amalgamated with the Toronto Electric Motor Co., and doing business in Toronto.

REPAIRS IN DOCK.

Editor THE CANADIAN ENGINEER.

SIR,—I recently ran across what I considered a rather smart piece of work. I was down at the wharf of the American Line in New York city, and noticed lying on the wharf a propeller blade, the tip of which had about two feet knocked off. I made inquiry, and discovered that it had been taken from the starboard propeller of the steamer "New York," which vessel was then alongside the wharf, being in the course of preparation for sea. It transpired that the job of removing this blade commenced just about 24 hours previous to the time at which I saw the men removing the gear and tackle used in dry-docking the propeller, as she was in wet dock. The work was commenced one morning at 10 a.m., the nuts slacked back, of which there were eight, perhaps 3½-inch diameter, the old blade removed, new one substituted, inside the period of about 24 hours. One can readily see what a saving is effected by being able to so make it possible to work in this way at a damaged propeller, and at the same time allow the cargo to be worked. I judge the weight of the propeller blade to have been about four tons. I have spent a night even in a dry dock slacking back nuts on jobs of this kind, and I consider this piece of work on the "New York" quite an example of ingenuity.

Yours sincerely,

JAMES J. SALMOND,
Box 388, Port Richmond, N. Y.

THE VENTILATION OF PLUMBING APPLIANCES.

We have received a letter from a writer signing himself "Plumber," in which he requests us to ask our sanitary correspondent to give our readers his views on the advantages and disadvantages of the present method of ventilating plumbing appliances and waste pipes, traps, etc. We have submitted the letter to our regular correspondent, W. M. Watson, Toronto, and have received the following reply, to illustrate which the accompanying drawings have been made:

In answering this query, let me first say that if "Plumber" had studied the articles on sanitary matters published in almost every issue of this paper for the past one and one-half years, he would have been already pretty well informed, especially by studying the one in the issue of April, 1897. The first and most important rule in fixing sewer and house waste pipes, is to

arrange every part, if possible, equally graded, with a constant rise upwards, so that a continuous supply of air will regularly pass through every portion except the traps, avoiding any air pockets, where air may lodge motionless and putrefy. See illustration I. in page 351 of the April, 1897, number of THE CANADIAN ENGINEER, except the sink pipes, which by mistake were shown wrong. The method of fixing vent pipes at the highest point of the bend, or knee, of traps, is wrong (see Fig. 1) and in a short time frustrates the intention in so placing it,

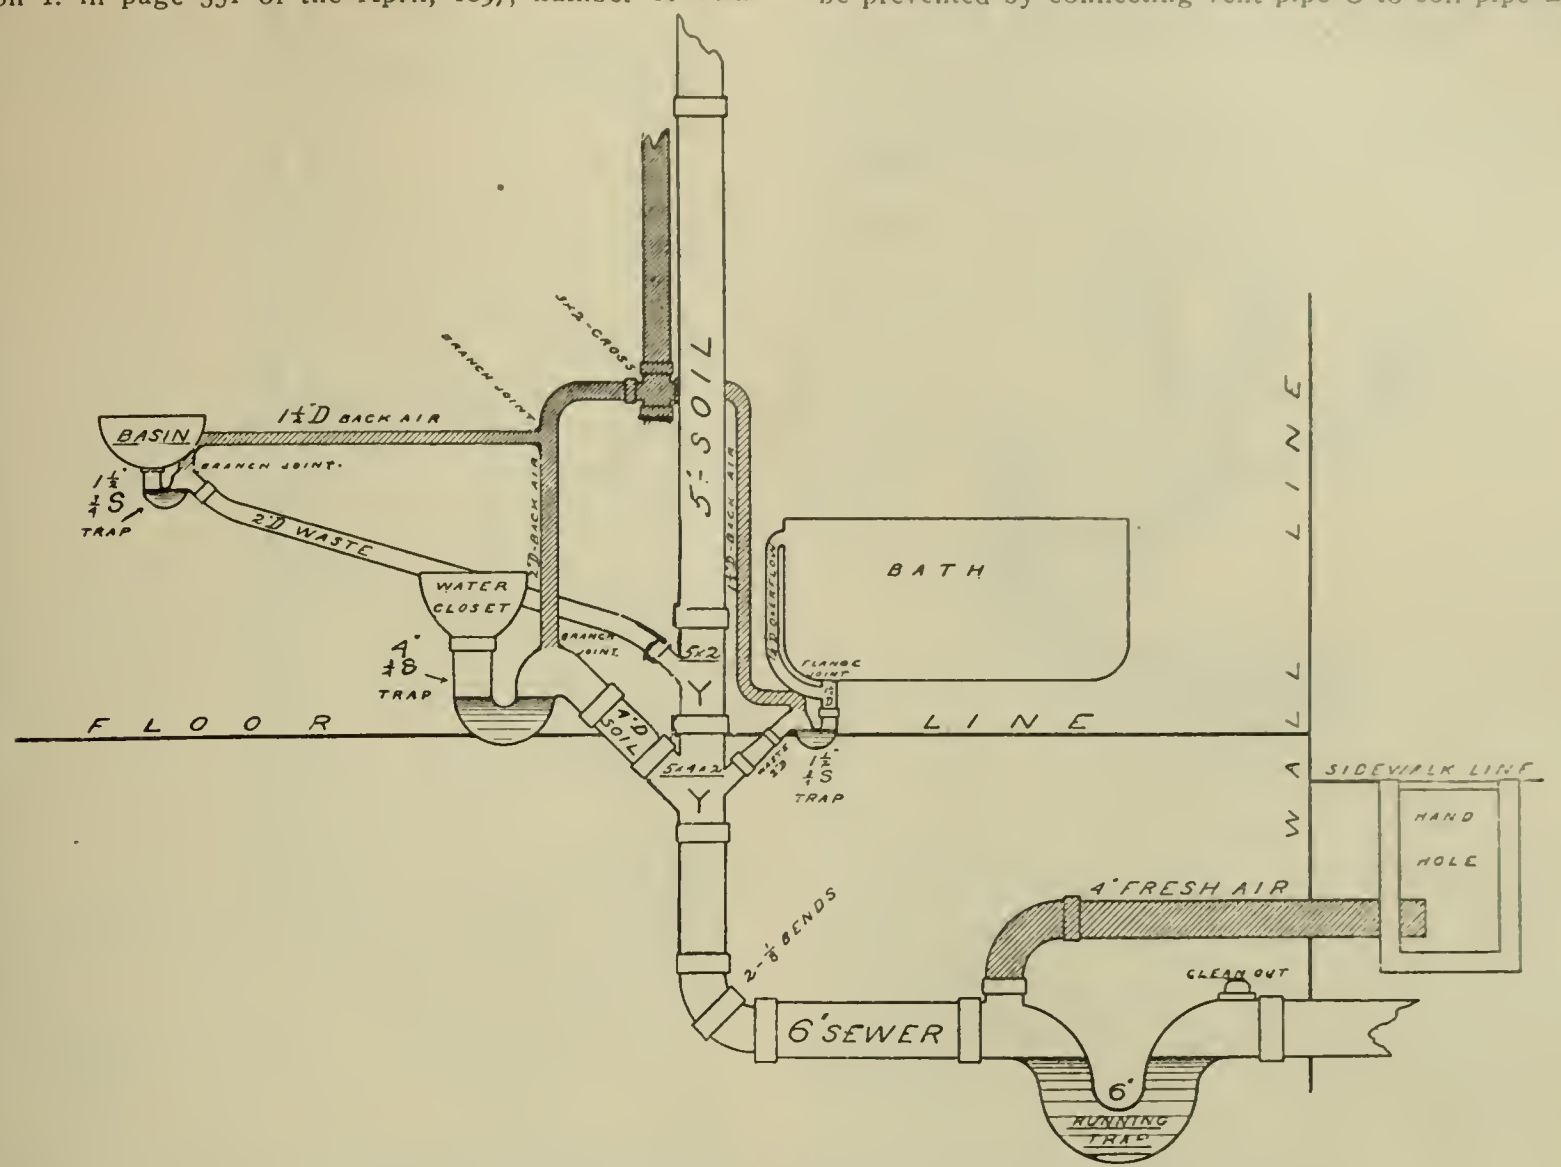


FIG. 1—PRESENT METHOD OF FITTING WITH BOTH PIPES THROUGH THE ROOF.

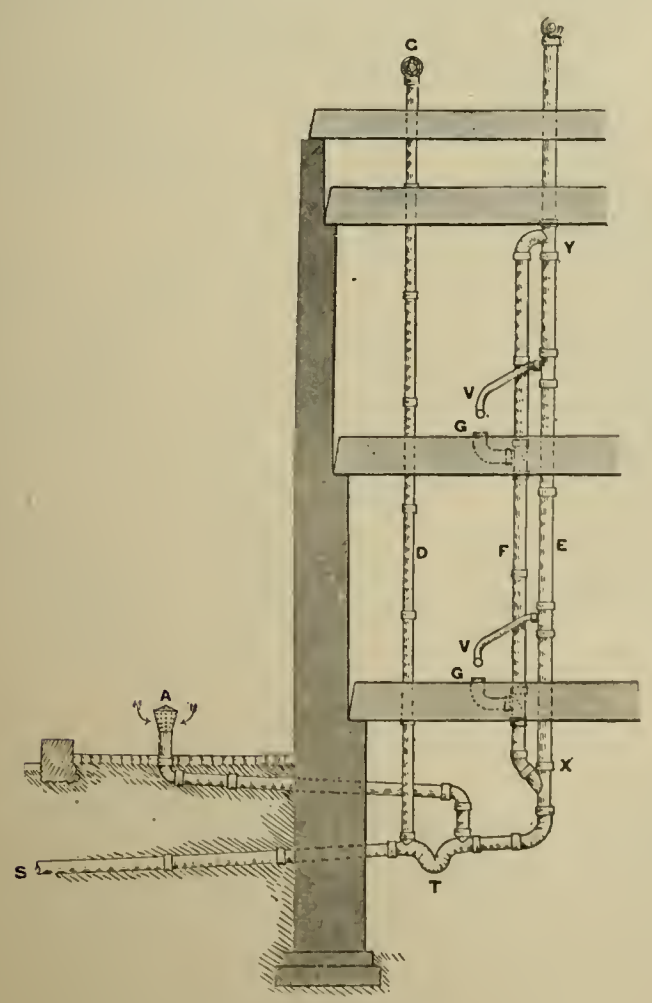

FIG. 2—SEWER VENT.

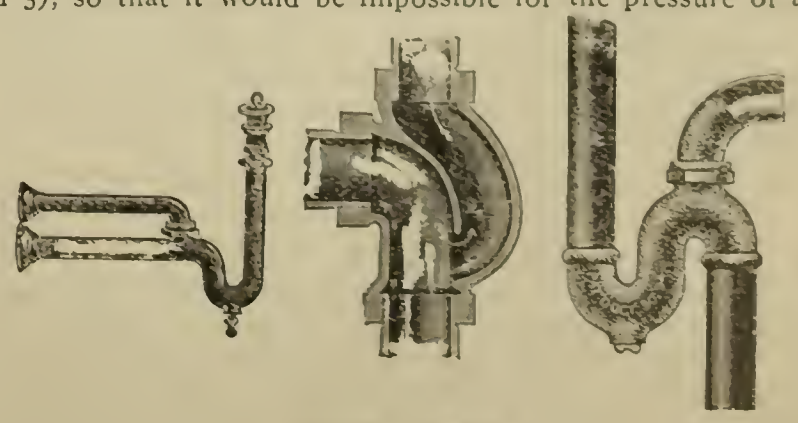
because each time that soapy water is forced round the sharp bends in the trap a froth is formed which flies up into the vent pipes and dries on like a coat of paint, gradually closing the opening until the pipe becomes useless. Moreover, wherever there is a separate stack for the use of ventilation alone (see Fig. 1), there is often a strong down-draught, varying momentarily, according to the pressure changes of the atmosphere at the terminating points, which causes an oscillation of the water seal in the most sensitive traps fixed on the line. That causes the seal to overflow, and break the key. This might partly be prevented by connecting vent pipe C to soil pipe B at junction, Fig. 2. Therefore, it is always safer to join the main ventilation pipe into the side of the soil pipe stack (see junction Y, Fig. 2), at a point before it passes outside, when in that case the down-draughts will act directly and squarely down the soil pipe to the main drain, or through the floor line breather pipe. The illustration in the April number will also explain this point still more. Then, vent pipes that are open to the outside air convey a drying atmosphere to the water seal, which quickly absorbs the moisture, drying out a 1½-inch trap very quickly, especially if the pipe is attached to a separate ventilation stack, or the vent is coupled in a way that the body of air presses squarely on the water seal contained in the trap (see Fig. 6 and Fig. 1), or there is hard, dry frost, or hot, drying air outside. They also often act as an overflow tank when the waste pipe is choked, because of the sewage forcing upwards into them when it can not freely flow downward by the proper pipe, gradually dribbling away down the waste pipe afterwards. They form obstructions, and often cause stoppages by small points of solder dropping in when wiping the joints, and also the roughness of the end of the vent pipe, peeping through at an intricate point where smoothness of turn is absolutely necessary. Therefore, if vent pipes are needed, they ought to be inserted a few inches backward from the crown of the bend (see Figs. 3, 4, and 5), so that it would be impossible for the pressure of the



FIGS. 4, 3 AND 6.

atmosphere to rest directly on the off-side of the water seal of any trap.

Plumbers may have noticed that the vents of English-made w.c.'s are never on the crown point, but act almost as a right

angle branch. They make it hard to remove a choke in a waste pipe that is vented, because a force pump is useless, the fluid passing up the vent when it ought to be making pressure in the waste pipe to force the obstruction.

The fad of the so-called trap syphoning is almost a canard. It can easily be done, but it does not occur naturally once in 100,000 times. There is a danger of the traps being drawn in places where soil pipes stop at the closets, and there is no vent of any kind through the roof, and the w.c. used is of the George Jinnings or Demarest kind, that drops about three gallons of

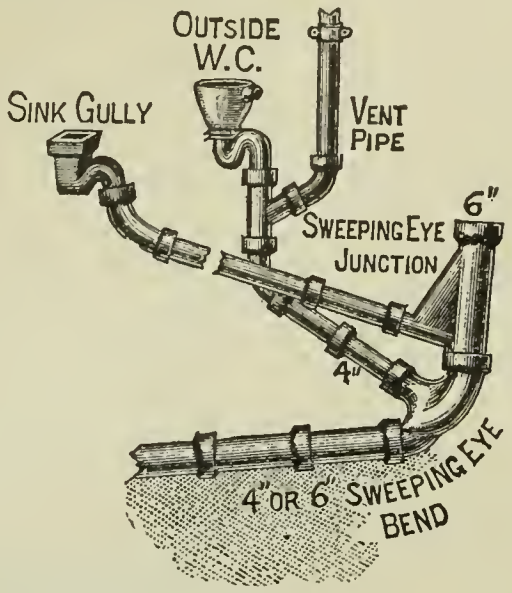


FIG. 5.

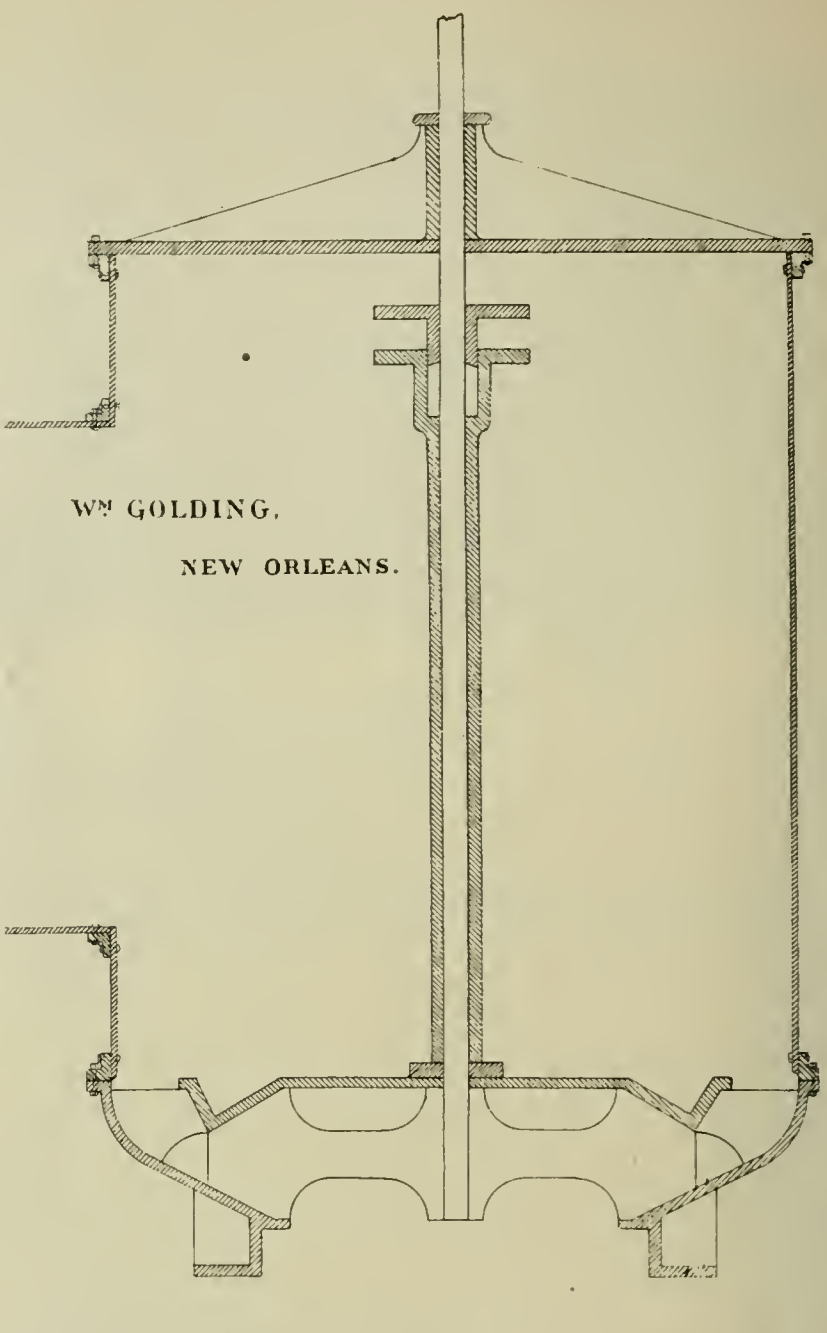
water and the excrements, etc., down the soil pipe suddenly, like a piston passing down a smooth cylinder, causing a considerable vacuum behind, because there is no vent pipe to bring in the atmosphere and fill the space, so it must needs draw it through the w.c. trap, and should it not have reached a larger pipe or sewer before the valve is dropped down again (of course backing the air from going that way), then the vacuum will draw any or all of the small traps in the house. But a water closet flushed by cistern and 1½-in. lead pipes can never syphon any traps, because the water and solids do not go down in bulk sufficiently large to fill a space of a 4-inch pipe, and the air will pass off in the opposite direction. Nor can syphoning ever occur where the soil pipe end is open above (see G. Fig. 2), and also sketch in last April number. The intricate fittings and methods of arranging pipes have caused more premature deaths than the well-appointed and carefully-constructed plumbing put in over thirty years ago, which was totally void of ventilation, but which also never had any dried-out water seals, which in Toronto are answerable for many deaths.

Three years since, I was privately engaged to go to a house having the best and latest designs and workmanship in plumbing throughout the place. I arrived in time to see some members of the family taken away by diphtheria, leaving only the nurse and another ill in the house. I proved enough to believe that it was the overdone plumbing and dried-out trap seals that hurt them, and if the eyes of those who understand air currents and sanitary matters were properly used, more such proofs of the danger of going to extremes in sanitary matters would be forthcoming.

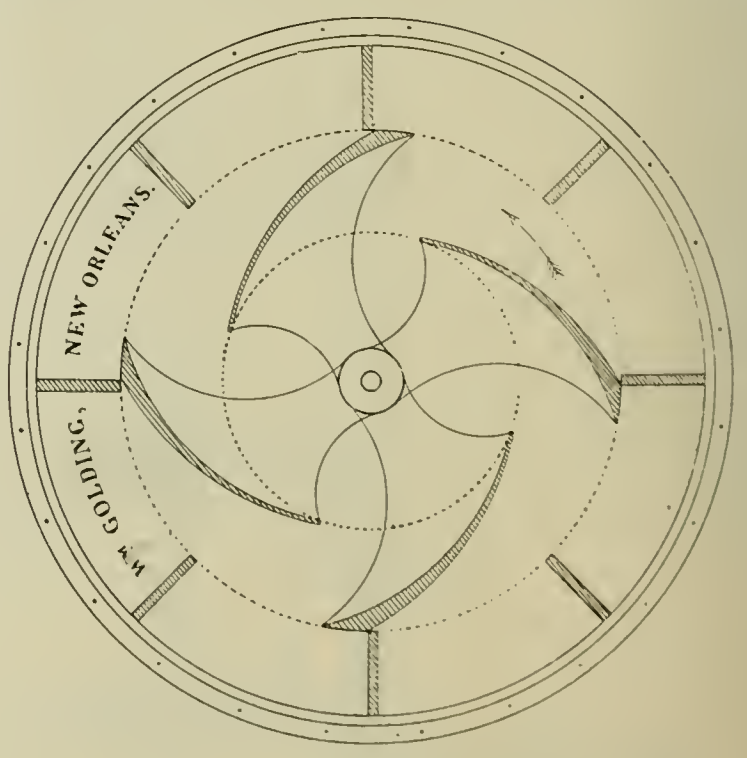
I have so far dealt with the evils of the present method of connecting ventilation pipes to waste pipes, and fixing them often where they are not needed, and where they do a real and positive harm, but the law requires them so to be placed, and though it was made probably by men void of practical knowledge and very ignorantly stupid in such matters, it must be carried out, if the whole town is injured thereby. In another article I will try to show the advantages the present method possesses.

CENTRIFUGAL PUMP.

The annexed sketches illustrate a type of centrifugal pump, the invention and design of Wm. Golding, C.E., New Orleans, La. The feature of this pump is the wheel cover, which rests in taper fit upon chucks, that are cast on the lower portion of the wheel box. There is no fastening to this cover, none being required, as the weight of the water will hold it down. Should the wheel break, or should any obstruction prevent its free movement, the cover and wheel may be removed from the case by simply taking away the upper spider. The lower part of



the discharge branch should be placed on a level with the minimum height of outfall receptacle, while the upper portion of discharge branch will be on a level with maximum height of outfall receptacle. The driving power will be attached to end of the wheel shaft above the spider. To ascertain the discharge



capacity of this pump, ascertain the cubic contents of wheel box (between dotted lines), and multiply by 4, for 4-bladed wheel, and by 5 for 5-bladed wheel, etc., etc., for each revolution of shaft, for the reason, as will be seen, that the wheel box is emptied four times per revolution. To ascertain the power required, ascertain the foot pounds in the quantity to be lifted, and add 50 per cent. The efficiency of this pump when properly installed is claimed to be 85 per cent of the power applied to the shaft.

THE PUBLISHERS.

EXTRACTS FROM ADDRESS OF GEO. E. DRUMMOND, PRESIDENT FEDERATED CANADIAN MINING TRUST.

Within the next few months Great Britain will pour into this, the first of her colonies, thousands of her sons and a vast amount of capital. The United States and other countries will contribute their quota in men and money, and Canada stands upon the threshold of a great national advance that means not only an early increase in material wealth, but what is equally important, that her natural resources shall at least be better understood and better valued both at home and abroad.

We who are directly interested in mining know that the Klondyke represents but a very small part of the great natural wealth of this country, and we are, therefore, confident that, properly directed, the workers and capitalists now coming to our shores, if by chance unsuccessful on their first adventures on the gold mines of Canada, can be absorbed to their own benefit and to that of the Dominion in many other fields of lucrative labor and investment which this country affords. The wealth of our coal fields and iron mines is undoubted. We are rich in silver, copper, asbestos, mica, plumbago, phosphate, chromic iron, galena, corundum, talc, and almost every mineral known to science.

Without presuming to dictate to our English and European friends, the members of this association may be permitted to express the opinion that the Canadian mining engineer, acquainted with this particular field of operation, experienced in the ores of this country, and fully understanding the climatic conditions under which the work has to be carried on, is better fitted to cope with and overcome natural difficulties than, for instance, an engineer who may have gained his experience on the free milling reefs of South Africa.

The official returns of the Geological Survey of Canada, just published, calculates the total production of minerals in Canada during the year 1897 at $28,789,173, an increase of $617,934 over the production of 1896. In 1886 the total production of minerals in Canada only reached a value of $10,000,000. What can better attest the importance of developing the mining industries of the Dominion than this advance of nearly 188 per cent in the short space of eleven years. . . .

In reviewing the different sections of mining, the address continued: The coal areas of the Dominion are estimated at 97,200 sq. miles, not including areas known, but as yet undeveloped in the far north. First the coal fields of Nova Scotia and New Brunswick; second, those of Manitoba and the North-West Teritories, and third, those of British Columbia.

The operations for 1897, so far as reported by the Bureau of Mines and the various companies interested show as follows:—

In Nova Scotia, coal raised	2,345,138 tons.
" New Brunswick, coal raised	6,000 "
" Manitoba and North-West Territories, coal raised	297,000 "
" British Columbia, Vancouver Island collieries, coal raised	798,458 "
	3,446,596 tons.

The production of coal for 1897 may be put down at a value of at least $7,000,000.

Coke—Nova Scotia reports the production in 1897 of 58,000 tons of coke.

We are without actual figures for the production in other sections, but it is gratifying to note that the coal companies of the Dominion are gradually extending their trade, export as well as native, through the medium of their coking plants.

Quoting from the Canadian Mining Manual of 1897: In 1884, 49 steamers, 18 sailing vessels, and two large barges were employed in the St. Lawrence-Maritime trade, when $360,680 were distributed for labor in transportation, trimming cargo, handling, etc., and $55,556 for wharfage, and $55,333 for pilotage. In all a total for these three items of $480,577.

Iron—During the earlier months of the year the Nova Scotian furnaces, as well as the one situated at Hamilton, Ont., were practically closed down, awaiting the decision of the Government regarding the tariff. That happily settled, the furnaces went to work (the Hamilton furnace as late as 29th June), with the result that at the close of the year the returns show an output of coke iron pretty well up to that of 1896 and an increased output of charcoal iron. Advices received from New Glasgow, N.S.; Londonderry, N.S.; Radnor Forges, Que., and Hamilton, Ont., report a combined gross production of about 57,904 net tons of pig iron, 18,562 net tons of steel, 1,403 net tons of forgings, 4,646 net tons of bar iron, puddled bar and other finished products, the three last mentioned items reported by the Londonderry Iron Co.

The capital invested, the number of men employed and the quantity of materials used remain practically about the same as in 1896. The output of charcoal iron at the Radnor Forges furnace, included in the above returns, shows an increase of 50 per cent. over the operations of 1896. The whole outlook in the Canadian blast furnace business is promising.

Our charcoal iron has taken front rank in point of quality, and so far as coke iron is concerned, Canadian founders now acknowledge the product for home furnaces to be equal in every way to the imported American article.

Ferro-Manganese—During the year the plant of the Pictou Charcoal Iron Company at Bridgeville, N.S., has been leased to the Mineral Products Company, who are undertaking the manufacture of ferro-manganese. The company has secured important concessions in manganese mines in Albert county, N.B. These operations will be watched with considerable interest by members of this Institute, who wish the new venture every success.

Chromic Iron—The returns for 1897 are not yet completed, but we are glad to be able to report shipments by the Quebec Central Railway to the extent of 2,593 tons. The quantity shipped in 1896 from the mines of the Province of Quebec, with points of destination, was as follows:

To Philadelphia	750 tons.
" Pittsburg	1,232 "
" Other points	55½ "

Mr. J. Obalski, Inspector of Mines, Que., estimated in his report for 1896 that during the preceding four years 10,500 tons of chromic iron had been raised, of which quantity 9,000 tons was shipped from the Province of Quebec. A concentrating plant is badly wanted to raise the values of a very large quantity of this mineral in the Eastern Townships, at present too low to market at a profit.

Mica—Quebec Province reports the total production to a valuation of $125,000, and we are also glad to report English capital recently invested in Ottawa County mines.

Phosphate—Some phosphate has been taken out during the past year in working for mica, and enquiries for this mineral are more numerous, although the prices offered are as yet too low to admit of actual business.

Gold.—Of all our mineral wealth, gold has excited far the greatest interest. . . . . The total production in Canada in 1897 is reported by the Geological Survey of Canada as $6,190,000.

The President then reviewed the conditions in the Yukon, British Columbia, Nova Scotia, Quebec, Ontario, and concluded: A matter of note is that important indications of gold-bearing quartz are found in the Sudbury district at Lakes Wahnapitae and Temogaming. This district, already famed for its deposits of nickel ore, is said to be very promising in gold.

Silver.—The total output for 1897 was 5,558,446 ozs., valued at $3,322 905.

These minerals continue to be the principal source of dividends in British Columbia, substantial profits having been realized by the Slocan Companies, among others the Payne, Whitewater, Peco, and the Hall Mines, Ltd. The figures for the past year are not yet reported, but they show an increase upon those of 1896.

In Ontario, a number of mines in the neighborhood of Port Arthur have been re-opened.

In Quebec important operations were begun, and shipments made from Calumet Island, Ottawa County. A valuable deposit of argentiferous galena has also been discovered in Brome County, on the shores of Lake Memphremagog, which is now being investigated.

Lead.—The total production in 1897 amounted to 39,018,219 ozs., a value of $1,396,853.

Asbestos.—The Geological Survey report gives the output of asbestos and asbestic as 25,262 tons, valued at $324,700. The shipments reported by the Quebec Central Railway for 1897 show:

Black Lake	1,020,425 lbs.
Thetford Mines	16,110,135 "
	17,130,560 "

It is pleasing to note the considerable trade that has sprung up for the refuse sand and short fibered asbestos for use as fireproof plaster, for which purpose it is admirably suited.

Copper—The copper ore mined in the Province of Quebec during 1897—39,928 net tons. Of this quantity 31,080 net tons went to the United States, the remaining 8,848 tons being treated in Canada. These figures show an increase over those of 1896 of 7,448 tons exported to the United States, and a decrease of ore treated at home of some 1,344 tons. The market in the United States has been in a healthy condition, with an active demand and well-sustained prices throughout the year.

In Canada the reduction of the import duty on sulphuric acid has resulted, as feared, in opening our market to the American manufac-

turer, in consequence of which there is a decrease in home production and also lower prices.

The Bureau of Mines of Ontario reports the production of metallic copper to the extent of 2,750 net tons, of a value at the works of $200,067.

Shipments of blister copper to Great Britain are reported by the Hall Mines smelter at Nelson, B.C.

Nickel—The Geological Survey Report for 1897 places the total production in Canada as 3,997,647 lbs., valued at $1,399,176.

Mr. Archibald Blue, Director of Mines of Ontario, reports:—

Nickel ore smelted in 1897	96,094 tons.
Metallic nickel contents	1,969 "
Value at works	$359,651

In certain quarters efforts are being made to induce the Government to impose an export duty upon Canadian nickel.

Gypsum.—The total production for Canada reached 239 691 tons. The output for Nova Scotia and New Brunswick combined reached 150,000 tons.

The other industries such as oil, natural gas, salt, graphite and building materials, show no specially new features, and returns of same are not yet to hand.

COMMERCIAL PROGRESS AS INFLUENCED BY THE DEVELOPMENT OF THE IRON INDUSTRY.*

Commercial prosperity is proportionate to the capacity of a country to produce what is required by its citizens, to its financial ability to sustain these products, and to the facilities for distributing what it is able to supply. Disclaiming any desire to minimize the important bearing upon national advancement which should be credited to the other specialties, the iron industry may be given the leading position. Few articles which we manufacture have been so liberally discussed by political economists as pig iron, and in legislation concerning customs' duties, this product has assumed such a prominent position that we may infer that this particular industry is recognized as exerting a marked influence upon the country and especially certain sections thereof. Facts sustain the inference that probably no one industrial pursuit, except possibly coal mining, has done more to advance the United States than the production of pig iron, and by this product and its subsequent manufacture much assistance has been given to the development of the coal mining industry which now contributes about 71,000,000 tons annually or 30 per cent. of the world's coal output. Having a general knowledge of what has been done towards the establishment of a Canadian iron industry and the efforts to encourage this by Government assistance, some application of the foregoing conclusions to the future of the Dominion may be expected at this time. The suggestions offered are not based upon detailed knowledge of local conditions, for I realize how much better equipped others are to discuss this subject locally. But it may be possible for one whose personal work has included numerous investigations of the adaptability of various locations for the establishment of iron and steel works, and whose examinations have embraced some of the deposits of the Dominion, to present new phases of pig iron production as exemplified in the records of progress of the United States, which may be applied to Canadian development. Canada is well supplied with iron ores, many of them of excellent quality; some have withstood any cost of transportation and paid duty for consumption in the blast furnaces of the United States, several hundred miles from where they were mined. The problem which seems to retard the Canadian industry is the bringing together of satisfactory fuels for smelting and ores of desirable character close to points of distribution or consumption. In determining the advisability of a district or individual location for the production or manufacture of iron or steel, the requirements are. (*a*) The facilities of obtaining raw material of satisfactory character, viz., iron ores, fuel and flux, their cost, and the character of metal which they will produce advantageously; (*b*) the market which can be conveniently reached, or which can be developed and the character of product most in demand; (*c*) the transportation facilities, both existing and prospective, and rates obtainable on raw material and finished products; (*d*) the supply and cost of labor, and the conditions which may cheapen or enhance the wage rate; (*e*) the relation which the local bears to other established concerns which may make similar products, and the competition which must be met from these; (*f*) the character of works which can be constructed, and cost; (*g*) the cost to produce pig iron, and to manufacture iron and steel of the forms most in demand; (*h*) the probability of other locations where no iron is made, but possessing equal, or in some cases superior, advantages, engaging in iron production; (*i*) In countries like the United States and Canada the trend of increasing population demands consideration. The problem is, therefore, by no means a simple one, and in the light of recent concentration of numerous plants under one general management or control this question of ample capital to build up, equip and operate works adds another factor.

*Extracted from a paper read by Jno. Birkinbine, Philadelphia, before the Federated Canadian Institute, Montreal.

In 1897 almost 12,500,000 tons of ore were shipped from Lake Superior mines to furnaces, some of which are 1,500 miles distant, the average distance between mines and furnaces using the ore being probably 800 miles. These ores have gone partly to meet the fuel, but the predominating attraction has been the market afforded for distribution of the metal produced and the articles manufactured from it. A brief summary of the development of the iron industry of the United States may be given in a statement of the rapidly increasing output of pig iron, this being the basis of the entire industry:

Year.	Gross tons of pig iron made.
1810	93,908
1830	165,000
1840	286,903
1850	563,755
1860	821,223
1864	1,014,282
1870	1,665,179
1872	2,548,713
1880	3,835,191
1881	4,144,254
1886	5,683,329
1887	6,417,148
1889	7,603,642
1890	9,203,703
1897	9,652,680

In the past three months the production has been at the rate of 12,000,000 tons per year. Taking the census reports for the half century, the data indicates that the pig iron output of 1890 was over 32 times that of 1840. Improved machinery and technical knowledge applied to iron smelting has done more than anything else to secure the advancement indicated. While pig iron is a most important factor in the development of a district, province or nation, its manufacture cannot be made successful without the use of good business management and technical knowledge. Even with this, failure may follow the location of plants without giving the matter thorough investigation.

Mr. Harvey Graham, who was called upon by the president, agreed with the remarks of Mr. Birkinbine, and drew attention to the immense amount of coal required to make 1,000,000 tons of pig iron per month —say, 2,000,000 tons of coal.

THE CHEMISTRY OF FOUNDRY PRACTICE.

BY ERNST A. SJOSTEDT.

(*Concluded from last issue*).

The powerful influence of sulphur in changing the character and fracture of the pig iron has more than once been forcibly brought to the personal experience of the writer, and an extreme case was met with several years ago at Kathadin Iron Works, Maine, with iron made from a bog ore that contained from 1 to 3 per cent. of sulphur, and which at the time was only imperfectly roasted. Analyses of several samples of all grades of this pig iron—from open gray to white and spongy—revealed the presence of sufficient silicon, which under ordinary circumstances would have made them all gray and soft, but the varying amounts of high sulphur present was here the determining agent, as we see from the following table:

No.	1	2	2	3	3	4	4	5	5	6	6	6	6
Silicon ..	3 05	3.10	2.35	3.55	2.00	2.74	2.70	2.22	1 30	3 89	3.05	2 73	1 00
Sulphur...	.03	.13	.18	.39	.19	.20	.34	.12	.18	.60	.46	.65	.43

Here, thus, we have a white iron with nearly 4 per cent. silicon, which but for the .6 per cent. sulphur present would have shown an open soft gray fracture.

An element we often hear about, and which when present even in the smallest quantity in steel is much dreaded, is *Phosphorous*. In foundry pig, however, a certain small amount is not only permissible, but highly desirable, as it lowers the melting point of the iron and makes it fluid, thus causing it to retain its heat longer and making it suitable for producing small castings of a delicate pattern. Pig iron with less than .2 per cent. P is apt to shrink. But when it is present to over .75 per cent. the iron becomes brittle—this in proportion to an increased percentage of carbon present—and strong castings should not contain over .5 per cent. phosphorous. It unites readily with iron to about 26 per cent., but the pig iron in the market contains from a trace to 1.5 per cent. Phosphorus is not eliminated in the cupola smelting, and its presence should therefore be kept run of.

Manganese is also an element to be taken in consideration in foundry practice, for so many iron ores contain this metal, and a certain

amount enters the iron during the blast furnace process, while part combines with the lime and the sulphur, and is removed with the slag. Its most striking property is to make the iron "chill," *i.e.*, prevents formation of graphitic carbon. But this chill does not make a durable wearing surface, as it is more crystalline than hard, and readily crumbles under the impact of rapid shocks (to which, *e.g.*, a car wheel is subjected). Its presence up to one per cent., however, is not considered detrimental, but a high percentage of manganese makes the casting brittle and white—provided the silicon is not exceptionally high, in which case (as in some Scotch foundry pig of good repute, which carry two to three per cent. of manganese), the graphite is separated, and a gray iron obtained. Iron alloys with manganese in all proportions, and when the amount of manganese runs between 20 and 30 per cent. the product is called ferro-manganese, and when containing from 5 to 20 per cent. it is termed "spiegel" iron. Manganese raises the point of saturation for carbon, *i.e.*, permits of a high total carbon. So while iron without any manganese rarely contains over 4.5 per cent. carbon, ferro-manganese often runs from 5 to 7 per cent. (nearly all of which is in the combined state). Owing to its affinity to sulphur, it acts as a "purifier" (even more so than lime), in the cupola, removing oxides of iron and silicon from the molten iron, and thus helps to prevent blow holes.

A metal which during the last decade has come in great favor as an admixture to iron and steel is *Aluminum*. [The credit of first calling attention to the influence of aluminum on iron castings belongs to a Swedish inventor who introduced the so called "Mitis" castings, a mixture of wrought iron and aluminum]. The principal effect this metal has upon cast iron is that it lowers the melting point of the alloy, consequently increases its fluidity and makes it run quick and sharp, besides giving the gases an opportunity of escaping from the molten iron, hence its reputed property of preventing blow holes. Like silicon, aluminum tends to make a gray iron, and lessens the tendency to chill (*i.e.* favors the formation of graphite), and if allowed to take the place of silicon it will make a stronger and softer casting than if silicon were the agent; but added to an iron already high in silicon it makes it weaker. An addition of aluminum, therefore, is beneficial only to a low silicon pig. If added in sufficient quantities (2 per cent. and more) aluminum, for the same reason as silicon, prevents shrinkage.

Other elements, such as titanium, arsenic, copper, nickel, chromium, etc., also exert their influence on the character of the iron, but they rarely occur in sufficient quantities to require looking for.

From what already has been said, it follows that carbon is a necessary, but passive component in the pig iron, made to change in amount and in form by the presence of other elements. Thus sulphur and aluminum tend to change the carbon into graphite, while sulphur, manganese and phosphorous do not cause carbon to leave its combined state. Sulphur, manganese and combined carbon increase the tendency to shrinkage, while silicon and phosphorous help to counteract this evil, and the more of the effective element the iron contains the more is its action facilitated or retarded, as the case may be.

According to the state in which the carbon is present in the pig iron its grading is determined; but as we have also seen how largely the proportional amounts of graphite and combined carbon are dependent on the many foreign elements present, and to a great extent also on the conditions under which the metal has been allowed to cool, it will at once be evident how uncertain and unsatisfactory it must be to try to judge the quality of the iron simply from the fracture it presents. On the other hand, it is not claimed that the physical properties of an iron are wholly dependent on a certain chemical composition, for there are several possible and proper compositions for an iron intended for any certain purpose, "each of which depends for its physical success on the manner of working the iron, as the full blast, temperature, etc., and on the relative proportions of one element to another, as well as on the actual amount ot each present." But before we institute chemical investigations we do not gain a true knowledge of what *causes* these different physical qualities in the iron, nor is it otherwise possible to ascertain the true composition of the pig iron or the cupola charge. In trying to remedy any evil, the first step to be taken, after all, is in the direction of discovering the *cause*, after which a restorative generally can be found. And, as said at the Foundrymen's Association in Philadelphia some time since, "in forming his deductions the chemist's mode of procedure is singularly simple, reasonable and practical. As a result of years of scientific experience, theory and actual practice, it is known that certain impurities in the material produce certain characteristic effects on its physical behavior; and these impurities may be eliminated, retained, or forced into combinations with others, according to fixed laws and conditions to which they are subject. There are founders who can get along without chemical services, but there are very few who could not obtain practical benefit from a use of the knowledge now obtainable upon this subject."

Montreal, February 10th, 1896.

THE STEAM ENGINE.

Editor CANADIAN ENGINEER:

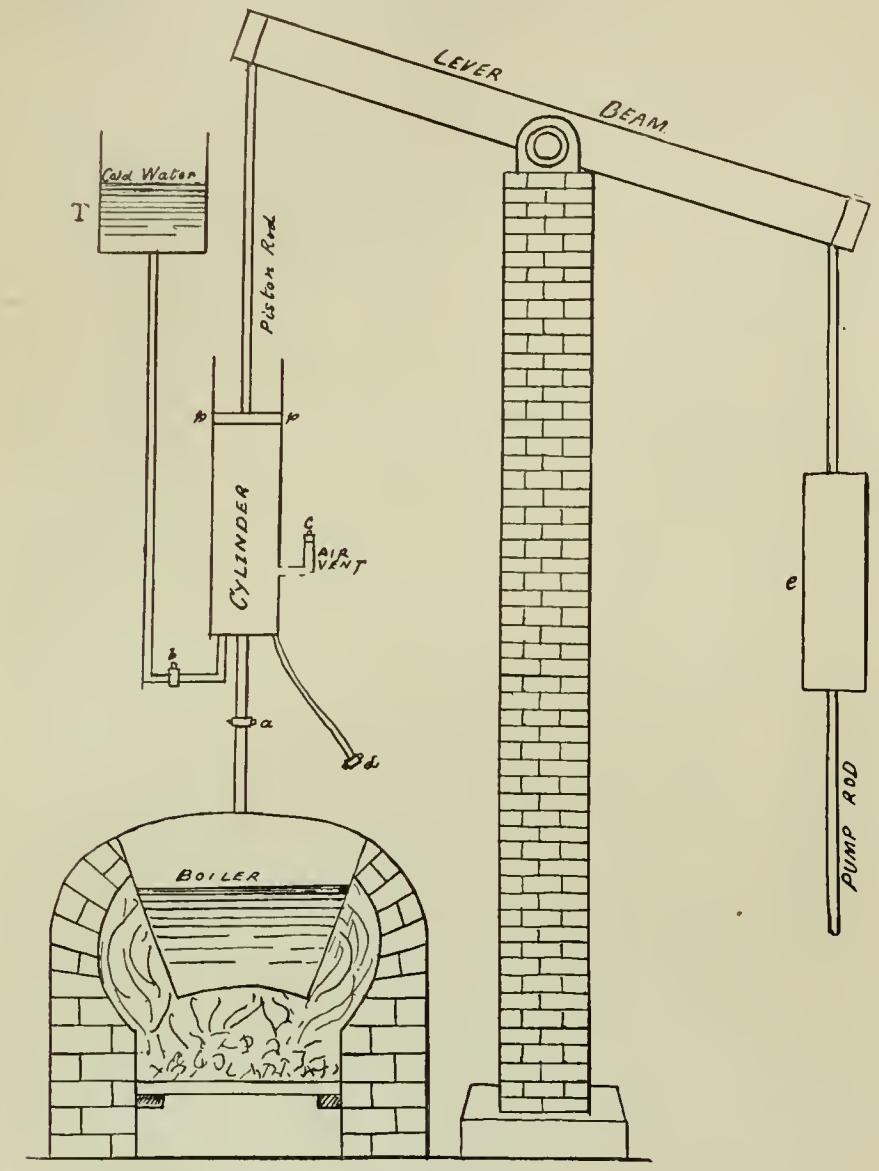
My last letter to you was on the setting of boilers In this paper I propose to speak to the young engineers and readers of your valuable journal, THE CANADIAN ENGINEER, and address them as my sons. I will now draw your attention to the horse-power, or the power of a horse and the duty which may be expected from a horse day after day; the power and duty of a steam engine or any and every machine has been and is now measured and compared with the power and duty of a horse as a unit.

Sixty years ago I was fifteen years of age and had served the first year of my seven years' apprenticeship in the boiler shop of one of the largest foundries in the west of England. My second year was designed to be spent in the erecting shop, so I had to spend much of my time among the mines taking down old and putting up new engines and machinery. My curiosity was aroused in looking through the storerooms of the mines. I saw many old tools and parts of machines. I made enquiry about their use. There in a corner lay an old leather bag or bucket, likely it had not been moved for many years. Being inquisitive, I asked the old storekeeper its use, and how long it had been there? He said, "many years ago, when I was a young man, about the close of the last century, 1790, instead of having an engine to pump the water from this mine, as you are now taking out, and the large new one you are about to put in, we had to draw it out with this leather bucket. A rope over a large pulley drawn by a horse, a heavy framework of timbers stood over this shaft with a large pulley on the top, and over that road the horse used to travel drawing the rope over it. A slow motion, but it had to be kept going. When one horse's eight hours were up another took its place, which would not keep the mine clear of water, being much deeper now and more men employed in bringing up the copper." Now a good reason was given for using leather bags. It would not knock down anything which happened to be loose on the side of the shaft, for the miners went up and down the same shaft. If the ore was brought up the same shaft it was made large enough to bare in a part for the iron bucket or cibble to pass up and down. Another pulley was provided and placed in the framework over the shaft for a chain to pass over in a groove.

The miners did not then go up and down in elevators as now, but had ladders placed perpendicularly fastened to the side of the shaft with iron rungs, and about every 100 feet a resting floor was made for them. I well recollect, after coming up six hundred feet over such a ladder, I was tired enough. The miners wore hard felt hats with wide brims to protect their heads and shoulders, with a piece of clay stuck on the brim and with a candle in it to give them light. There were no matches and Davey lamps as there have been since; it was a very unfortunate thing for them to lose their light. I one time went into a place like a large room; there was not sufficient air to feed it. My light was gone, all was dark; I had to grope my way to the nearest wise man, whose light still burned (you young men be sure you do not get into such a position with your excited mining speculations). It is very nice to hear the voices of the miners coming up the shaft, singing some well-known tune in their lively meeting houses and keeping time with their feet on the thaves of the ladders as they go up and down, and sometimes at their work, to go through a well regulated mine and ramble through long tunnels, observe the way they work to get out the ore; sometimes it is not all pleasure nor profit to the worker, nor investor—but I have wandered off, I must return to my text.

The horse power, and his duty drawing up water for eight hours per day, was an important subject in the year 1698. Some 300 years ago Captain Savery obtained a patent for a steam engine, to draw up or force up with a pump the water from the mine instead of the horse arrangement, he called it the miners' friend, and after he had it going he found his engine would force up as much water as twelve horses in a day, then he called it so many horse-power. Their cost also had to be compared, to calculate the advantage of using steam (that great natural force they had learned to bridle and harness); it soon became noised through the mines and country that the horse had been superseded by the steam engine, for it could run night and day for less cost than the three horses. The excitement caused a number of the thinking men to turn their attention to making steam turn the mills, factories and other machinery. Companies were formed and a great deal of money spent. Newcomen, Cowley and Savery formed one company in England, others in Scotland built foundries. Steam was the great topic of the day. This Newcomen Company got seven teams of horses in a field, in a ploughing match. It was found the average weight a horse could draw through the day was 163 pounds,

and travel 2½ miles per hour. Another trial was made by them some time after with 144 horses drawing a weight with a rope over a pulley eight hours per day, to be on the average 150 pounds, and traveling 2½ miles per hour; but the most direct way for them to get at the



NEWCOMEN ENGINE.

(*a*) Stopcock between boiler and cylinder; (*b*) Stopcock between cold wate tank and cylinder; (*c*) Valve closing air-vent; (*d*) Valve closing the outlet for con densed steam; (*e*) Weight which drags down the beam; (*pp*) Piston which is pressed down by the atmosphere when the cylinder is empty.

power of their engine was to find how many gallons of water a horse could draw up in eight hours out of a mine so many feet deep, which they did, and found their engine would force up as many as 100 horses in the time; the horse-power to them then became their unit or standard for making their engines.

In 1705 this Newcomen Company was formed. Newcomen, being a very active man in business, made a model engine for the University of Glasgow of brass about the year 1710; the cylinder was two inches diameter, six inches stroke (this engine had some improvements over Savery's); the boiler was made of copper, nine inches diameter, without a safety valve. At times the steam rose too high, 75 to 100 lbs. per square inch, but had to be governed by the regulation of the fire. The cylinder of this engine stood directly over the boiler, and was connected by the steam-pipe. This cylinder had a bottom, but no cover for the top, so that the piston could be seen and the air-press on the top of it. This pressure of about 114½ lbs. per square inch is the power of the engine. The cylinder being 2 inches by 2 inches by 7,854 = to 3.1416 square inches on the piston, by 14½ lbs. atmospheric pressure, gives about 45½ lbs. on the piston, so that whatever size engine was required the size of the piston was given and number of pounds expected of it, providing the piston was airtight in the cylinder, and a good vacuum was formed under it by the steam raising the piston up again. The steam was then condensed and the cylinder cooled by a spray of cold water let in, and was let off from the cylinder. A part of this warm water was used to feed the boiler. The tap or valves had to be opened and shut by hand every stroke. One day the boy, Humphrey Potter, wanted to be relieved of his duties; he saw he could tie a lever and a string to the working main beam to do his work. The piston rod was fastened by a chain to a wood beam one end and the other end to the water pump. To such ingenious boys we are greatly indebted for our many improvements we have to-day. This engine remained in the museum of the University for many years. A number of professors and students looked at it and passed by. Sixteen years after it was made, a little boy was born in Greenock; his father rejoiced and said he had a man from the Lord, and called his name James Watt, 1736. Being a mechanical ship-builder, he trained his boy to be mechanical, too, by giving him tools to use when out of school. Being rather weakly, his mother kept him home and taught him good, scientific knowledge and honest principles. At the age of 12 years he was found by his aunt in her kitchen, watching the steam coming out of the spout of the kettle; he stopped it from coming through the spout and put a weight on the cover to see what it would do. The steam rose and blew off the cover, and some of the water into the fire. This caused his aunt to come and see what had happened. She scolded him for wasting his time and the water she wanted and told him to go home to his mother. Her displeasure did not stop his thinking about the much talked of steam among boys and men; of what it was doing in the mines taking the place of the horses. At the age of 16 years, Watt was sent to London to learn the art of a mathematical instrument maker, that was then one who made clocks, fishing tackle, sailors' compasses, quadrants, doctors' tools, university and school instruments, and a variety of things to be repaired. At the age of 21—1757—he left London and went to Glasgow, opened a little repair shop for anything he could get any money by, for he had to depend on his own income, as his friends were much reduced by heavy losses. The professors and students of the university visited his shop for repairs; that same year he was appointed instrument maker, and had rooms provided for him in the University of Glasgow. Among many other tools he had to repair was Newcomen's engine, and to see further what it could be made to do, as for 47 years little had been done with it. He soon discovered its great defects and what was wanted, he found it took six pounds of cold water to condense one pound of steam (one pound of water will make one pound of steam) and cool the cylinder so as to form the vacuum required; the great idea struck him if he could keep the cylinder hot and get clear of the steam, he could put a cover on the top and cause the piston to descend by the steam with much greater pressure than by the air 14½ lbs. His mind seemed to be fully occupied, that he could not think about anything else. One Sunday morning as he was going to church his hands were not engaged, but his mind was fully absorbed about the engine; a voice seemed to sound in his ears from someone beside him, "get another cylinder and carry the steam from the top and the bottom of the piston and condense it there with a spray or jet of cold water; your engine will go faster and be of much greater power, as the steam can be raised much higher by having a larger and stronger boiler;" everything seemed to be clearly marked out before him for a real steam engine to be used in factories, steamboats and land carriages. He became much excited over the vision in his mind, he could not follow the preacher in his sermon. A very great obstacle stood in his way, that was, the money it would cost to try his plans; he drew his plans and talked it over with Dr. Black, Dr. Roebuck, Dr. Ure and other friends, who agreed to assist him. He then withdrew from the University and devoted his time getting out his patterns and castings to get his engine to work. Here we had better let him carry out his plans, and we will observe him going from pattern to molding shops, machine to erecting shops, directing his workmen until his engine is finished and working. Dr. Roebuck and other friends provided the money and gave him room in the Carron Iron Works.

In summing up our standard of measure or unit we now call the horse-power. We must borrow an idea from Mr. Watt, and make our figures and calculations as simple as possible. I will now suppose the water in the mine to be about 206¼ feet to be drawn up, the bucket and rope to weigh about 125 lbs., and the water 287½ lbs., 28¾ gallons, or the whole 412½ lbs. The rope and bucket will descend by gravitation. The travel of the horse for the first draw will be 206¼ × 2 = 412½ feet, and if this be continued ten times per hour will give 4,127½ feet for the horse to travel and 4,127½ lbs. to draw, and if continued for eight hours a day, which is considered a day's work or the duty of a good horse, will give 33,000 lbs. drawn up over a pulley 33,000 feet or 6¼ miles per day. This gives 1 lb. to the foot, or as it is now called, a foot pound. If a horse could raise 33,000 lbs. one foot in a minute it would be considered a day's work, or the duty expected from him for a day's pay, as much as if he had taken eight hours. This is called the nominal horse power, and if a machine, steam or moved by any other force, can be made to do or exert that amount of force or work in one minute, or eight hours, it is called one nominal horse power, or if it can exert 100 horse-power in a minute it is called 100 nominal horse-power.

In bringing this subject to a close I think it wise to lay before you the cost of raising 33,000 lbs. or 2,300 gallons out of the mine 206¼ feet deep, and the horse has traveled 33,000 feet in eight hours. The horse should be well stabled and fed with an allowance of 25 lbs. chopped hay and a half a bushel of oats, beans and bran ground, about 40c. per day, a man's wages $1 for attending to it, and other expenses $1.50 per day. The first outlay equals about $300, interest $18.

In this paper we have seen a little into the workings of the steam and the atmospheric engine; in my next paper, if you, Mr. Editor, can find room for the little light I can bring before the readers of your valuable journal, I propose to follow our dear old friend, Jas. Watt, with his improvements, and trace down a little of what has been done since his death in 1819.

Yours truly,

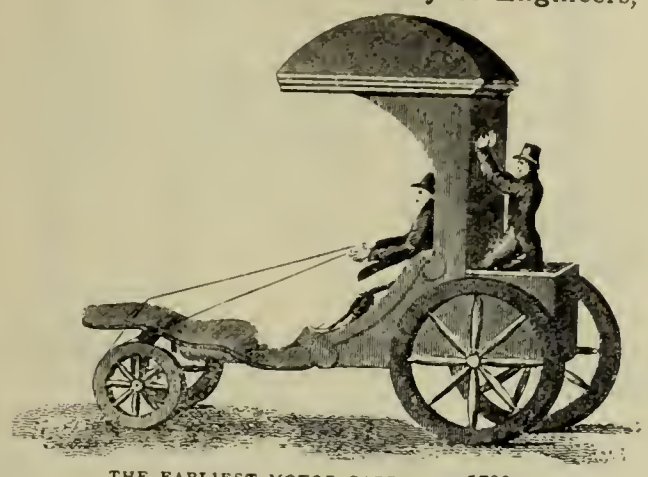
P. T. TROWERN,

Feb. 15th, 1898. Chief Engineer Asylum for Insane, Toronto

THE MOTOR CARRIAGE.

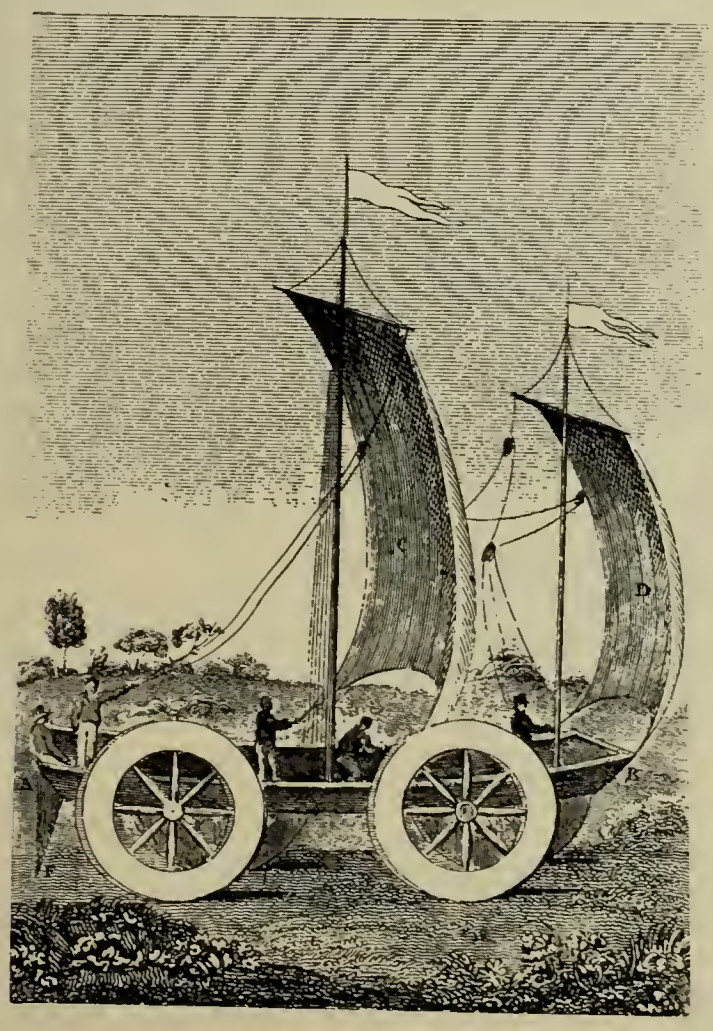
PAST AND PRESENT.

"With the exception of lands and ruins, there are few material things of value to man which do not derive that value, in part at least, from transport from their original position Cheap means of transport is one of the most important of all the subjects occupying engineers to-day, and one which offers, as it has always done, one of the most profitable sources of investment."—Worby Beaumont, M. Inst. C.E., M. Inst. M.E., M. Inst. E.E., President of the Society of Engineers, England



THE EARLIEST MOTOR CARRIAGE—1796.

The earliest motor carriage—a hundred years ago. The carriage shown was not strictly an autocar or automobile, but rather a manomotor, and the man who "moted" was in a double sense a footman. The pedals are crude bicycle pedals, therefore this curious old engraving represents the ancestor not only of the modern motor-carriage, but of the bicycle. As for the sailing chariot* or airmotor, the present-day prairie schooners would stand no chance in a cyclone-race with this Flying Dutchman. It was, too, picturesque, and had no massive storage batteries to be charged; no ponderous fly-wheels—though



THE SAILING CHARIOT.

This chariot was constructed in the last century by Stephinus, at Scheveling, in Holland, and would carry 8 or 10 persons from Scheveling to Putten, 42 English miles, in 2 hours. The wheels require to be farther asunder, and the axletrees longer than in ordinary carriages, to prevent overturning. Carriages of this kind are said to be frequent in China. In any wide level country their use must be sometimes both pleasant and profitable, when the wind is right.

all four wheels fly; no water-jacket; no missing of explosions; no odors to offend the passers-by, or noise of escaping steam or exhausting gases to frighten horses. Of course if the wind happened to be in the wrong quarter, the ship simply lay-to and "waited the turn of the tide." So much for the past: these old engravings certainly mark the first definite attempts at the solution of the motor-carriage problem, and it is with pardonable pride THE CANADIAN ENGINEER presents them for the first time.

What about the present? It is a time of unwonted activity among the inventors, engineers and mechanics. Thousands of the brightest brains in the world are struggling with the complicated problem of mechanical traction. Engineers who have made a special study of this question are aware of the peculiar difficulties it presents. That mechanical skill will finally triumph we firmly believe; and as seven cities claimed the honor of Homer's nativity, so will all civilized countries do homage to the genius who with seven-league boots shall stride in this mechanical Klondyke and show the world the way.

THE LATEST MOTOR CARRIAGE,—1898.

One of the most hard-working students of the motor problem is W. J. Still, who for nearly seven years has been experimenting in Toronto with the various types. The history of his failures would make interesting and profitable reading, but it is only of his success we have room to tell. Mr. Still's first experiments were with electricity, but although his work in this

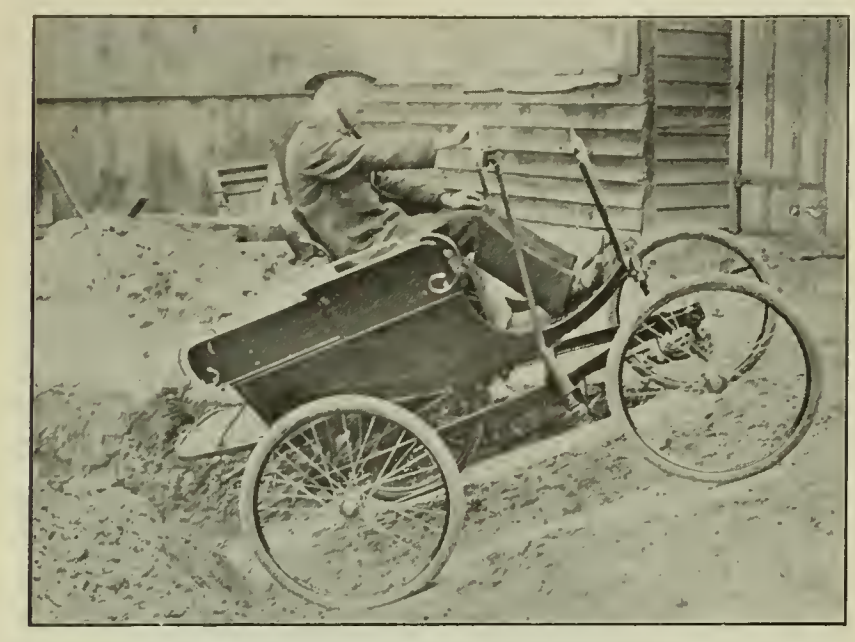
CANADIAN MOTOR CARRIAGE.

Front view, showing steering gear and controller. Hand wheel used for steering. Mr. Bengough at wheel; Mr. Still to his left. Weight of motor, 3.0 lbs. Entire weight of carriage (unloaded), 750 lbs. Power of motor, 5 h.p.

connection encouraged the young inventor, he fully recognized that electricity has severe limitations, the most serious of which is the absolute necessity for recharging. This consideration

*For the engravings of the "Earliest Motor Carriage, 1798," and the "Sailing Chariot," we are indebted to Thomas Bengough, of Toronto, who, having the motor-mania, and being a book collector, recently captured the precious old volume containing the original engravings on steel.

alone puts the storage battery out of the race for running through districts where charging stations do not exist. Mr. Still's attention was therefore turned to gasolene engine construction, and following his radical bent, he determined to avoid altogether the weak points of all gasolene engines, viz., rapid piston movement, complicated cycles, and differential gearing: fo these features involve practically all the troubles that beset the motor carriages to-day. The sequence is made up thus:

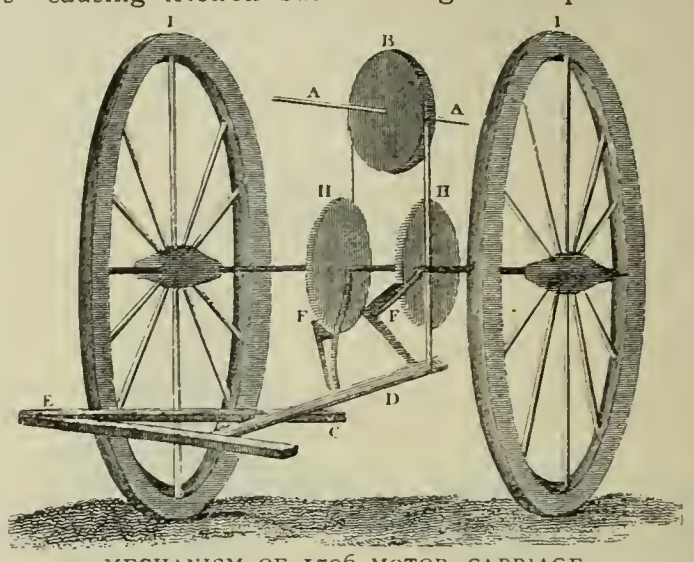


CANADIAN MOTOR CARRIAGE.

On grade specially constructed to scale of 1 in 3. As soil was soft, boards were laid for wheels so as to reduce tractive force and make test as severe as possible Brakes had not been fitted to rig when photo. was taken, and carriage is held in position by its own motive power.

(1) Rapid piston movement—600 to 1,000 revolutions per minute—causing immense heat, often up to 1,500 deg. or 2,000 deg. Fah.; this high temperature in turn necessitates the use of heavy oils, which at great heat give off bad odors. It also requires a water jacket and cooling water tank, with pipe system for circulation of water and radiation of heat. All these points involve great size, weight, and cumbrousness in proportion to load. (2) The complicated cycles, in which frequent misfires occur, involve very bad odor by the unused gas being emitted through the exhaust. The piston thus receiving no impetus, a heavy fly-wheel is essential, and this adds further weight and clumsiness. (3) The elaborate series of differential gearing add immensely to size, with no advantage except varying the speed of transmission. Sir David Salomons considers all differential gearing such a nuisance that he frankly says were he a manufacturer he would willingly give £20,000 to be entirely rid of it. Following on the heels of the heavy and complicated mechanical construction above noted, come noise and vibration. There also comes a loss of power in proportion to size and weight of mechanism. The highest record of power exerted by a motor carriage up to date was 187 pounds draw-bar strain, while the carriage (unloaded) weighed over 1,200 pounds. A good horse—such as Watt used to obtain his standard "horse-power"—will pull 400 pounds; therefore, 187 pounds is less than one-half horse-power.

To remove at one stroke all this complication, with consequent losses and disadvantages, was the herculean task to which the young inventor set himself. The essential point was to discover or invent a new cycle. There must be no "false motions" causing friction but resulting in no power. There



MECHANISM OF 1796 MOTOR CARRIAGE.

This carriage was exhibited in Paris, France, last century, by Dr. Richard, of Rochelle. When the footman presses down one of the treadles, suppose C, with his foot, he brings down one of the pieces of iron, F, and consequently turns the wheel H, that is next to it. At the same time, by means of the rope that runs over the pulley B, he raises the other treadle D, together with its piece F, which, being thrust down, will turn the other wheel H, and so alternately; and as the great wheels are fixed on the same axis, they must necessarily move at the same time.

must be no mechanical absurdity, such as is involved in the process of creating intense heat and then taking it away by a cumbrous round-about process of cooling. There must be a further feature superadded, which does not exist in any gas or gasolene engine; which exists in a limited area in the storage battery, which is found in perfect form in the steam engine: that feature being the ability to give off for short periods much more than normal power. In the case, for example, of the carriage referred to, 187 pounds would be easily sufficient to propel 1,200 lbs. on a level, but what would happen when a hill is reached? Sir David Salomons, one of the greatest, because most disinterested authorities on the autocar question, lays down this rule as to power of motors for carriages: "If twelve miles per hour be fixed as the speed of a vehicle weighing, when laden, say one ton, then the power of the carriage should be sufficient to run at this in all weathers and over all highways, and to climb every hill with a maximum ascent of, say, one in ten, at the proposed rate. The vehicle should also be able to mount a hill of one in five, but at less speed.....I have come to the conclusion that, for every ton, not less than ten horse-power should be carried." This, it will be noticed, is the exact proportion of power developed in the Canadian motor carriage. Sir David continues: "This does not necessarily imply that a ten horse-power engine is required. It means that the engine shall, for considerable periods, and without injury to itself, be able to give off 10 h.p. It must be remembered that when the carriage is started, a far larger amount of power is necessary than when it is running. It is therefore very important to have a good reserve." Sir David then quotes valuable figures to show the varying power needed according to the grade, taking

PASSENGER AND PARCELS AUTOCAR

Now under construction by Canadian Motor Syndicate for the St Germain Autocar Line. Scale of drawing, ¼ in. = 1 foot. Van to seat 25 passengers; equipped with motors producing 20 h.p.; capable of ascending all grades up to 1 foot in 3; lighted by electric light; furnished with special indicator, for motorman; strong, effective brakes of two separate designs; seats to be handsomely upholstered; windows to have automatic spring roller blinds; roof railed for parcels.

a stage coach weighing 1,800 pounds, exclusive of passengers, thus :

Grade of 1 in 40, 6 miles per hour, required ....160 lbs.
" 1 in 30 " " .....165 lbs.
" 1 in 26 " " .....213 lbs.
" 1 in 20 " " .....268 lbs.
" 1 in 40, 10 miles per hour, requires....172 lbs.
" 1 in 30 " " .....200 lbs.
" 1 in 20 " " .....318 lbs.

On this point it may be interesting to quote from Mr. Worby Beaumont, whose quotation heads this article: "The increase in the power required to haul a load up a hill is directly proportional to the angle of inclination from the horizontal, and hence on a hill of one in twenty, a very common gradient, the hauling power jumps from the average, on a good macadam road, of say 45 lbs. per ton to 51 + 125 lbs., or a total of 157 lbs. instead of 45 lbs. Bad as this is, it is insignificant as compared with the pull required on a gradient of one in ten to one in eight, not at all unfrequently met with. On one in ten the hauling power required becomes 269 lbs. instead of 45 lbs., or no less than six times the power required on the average nearly level road. It is to meet this heavy demand for power that two or three horses have often to be sent with a load which, but for the one or two short lengths of steep hill, could be taken by one horse, and it makes it necessary to put on a motor vehicle boiler and engine power of from 12 to 16 horse-power, where from three to four horse-power would be sufficient."

Mr. Still set himself to solve this difficult problem, the peculiarity of which not even engineers understand who have not studied it in detail; for it must be remembered that the addition to a motor carriage of the boiler and engine power spoken of by Mr. Beaumont would in itself be fatal to the actual work of the motor carriage. Mr. Still's aim was to secure a draw-bar strain equal at least to one-half the total weight of the vehicle. His system is practically in itself a differential gearing of unlimited scope. It allows of a speed gear from the motor, beginning at the ratio of 1 to 1, and running to an almost unlimited scope, certainly over 120 to 1—the latter range having been actually reached in shop tests; this being entirely automatic according to the draw-bar strain required, and without any dividing line on either ascending or descending scale, and without belt, friction or gear-drive.

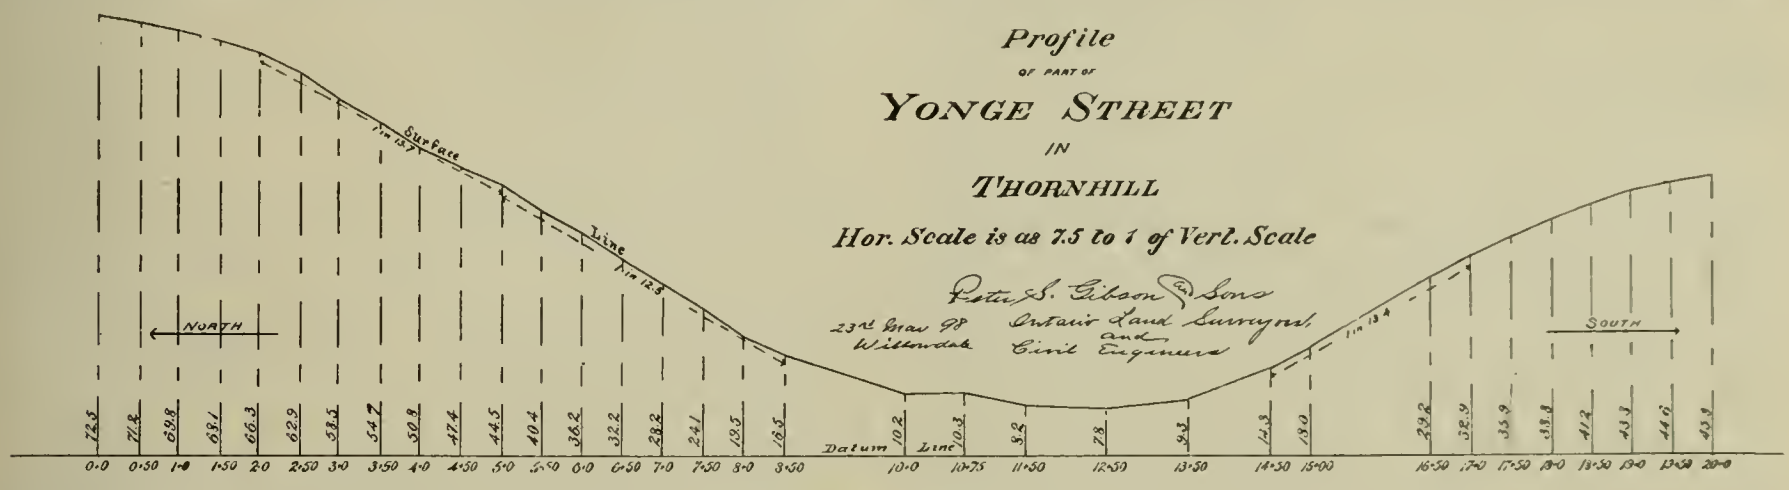
The Still system of motor power as it stands to-day, is unique in the fact of being able to place and maintain a rig in any desired position on any grade. This feature is admirably shown in the photograph representing the carriage standing on a grade of 1 in 3, the draw-bar strain being exactly proportioned to gravity and friction. No brake is involved in the operation: it is simply a question of a balance of the motive force; and about 20 lbs. in either direction would have overcome the balance and moved this rig, although at the time in question the outside draw-bar strain necessary would amount to about 270 lbs. This same force can also be used for sudden stopping in descending grades in case of emergency, and would not only stop a carriage, but rapidly propel it backwards the moment sufficient tractive force were obtained to stop the wheels from skidding. The control is simple. You simply push the controller forward if you wish to go forward; if you wish to go faster, you push it further forward; if you wish to stop, you pull the controller back; if you wish to reverse, a small lever, movable to the left hand, if pulled towards the rear, reverses the mechanism. This can, if necessary, be done at full speed without injury to the machinery. Steering is controlled by a hand-wheel on the controlling lever. Two separate powerful brakes are also provided, one operated by the foot and one by the left hand. Mr. Still's motor is a new departure. There is no sound of an exhaust; there is no odor of combustion, there is no heat; there is no necessity for the cooling water-jacket. In the rig as now standing, there is no water used or required. High speeds can be maintained, or the governor can be so adjusted that no speed above a certain maximum can be obtained, so that in case of delivery vehicles driven by careless Jehus, reckless driving will be impossible.

The motors used in this vehicle may be extended along the whole line, from a small bicycle unit to the unit necessary to drive ocean liners, including invalid chairs, all kinds of road vehicles, launches, street cars, railway engines and stationary engines.

It will be noted that the machinery in connection with the Canadian motor carriage is almost invisible, and not a line of the construction of the body has been changed. This carriage body is one of the regular make of the Canada Carriage Company, Brockville. Nothing has been done with it excepting that part of the flooring has been removed to allow room for the motor. The total weight of the engine is 300 lbs ; engine and truck together (including wheels), weigh 600 lbs.; the body of the carriage, controller and springs, add about 150 lbs., so that the total weight complete without load is 750 lbs. The load shown in the engraving (4 persons) is somewhat over 600 lbs. The carriage would easily accommodate its equal weight of load. Thus the proportion of weight to load is reduced to pound for pound, which is a reduction of about three-quarters of the ordinary weight of motor carriages. The power of this 300 lb. engine is equivalent to five horse-power. Thus the Canadian motor carriage combines the maximum power with minimum weight, and marks an epoch in motor carriage construction. A sudden development of the motor carriage industry in Canada has come within the past month. A. H. St. Germain, of North Toronto, has for over a year past been investigating the question of autocars, with a view of putting a service on the line between the city of Toronto and Richmond Hill, the service of the Metropolitan Street Railway up Yonge street—the main thoroughfare of the County of York—being very unsatisfactory. Mr. St. Germain is a wealthy gentleman, who lives at Bedford Park, about four miles north of the city, and he has personally suffered with others the inconvenience of the irregular service given by the Metropolitan Line. He had been corresponding with English autocar makers in reference to a number of storage battery omnibuses, but after having a private view of the Still engine as running upon the truck before the Gladstone carriage shown in the engraving was completed, Mr. St. Germain was convinced that his was the power he needed, and at once closed a contract with the Canadian Motor Syndicate, who control the Canadian business in connection with Mr. Still's inventions. This contract provides for the immediate construction of an autocar such as shown in the large engraving published herewith. This autocar is being constructed with all possible speed, and will take the road in the early summer. The following are the main features of the construction contract for the St. Germain autocar:

"Van to seat 25 passengers; equipped with motors producing 20 horse-power; capable of ascending all grades up to 30 per cent., lighted by electric light; furnished with buttons and special indicator by which motorman may be ordered to move to right or left boulevard, or stop suddenly; strong, effective brakes of two separate designs; seats on either side of middle aisle to be handsomely upholstered; windows to have automatic spring roller blinds; roof railed for parcels; everything to be of the best style and workmanship."

The route of the St. Germain autocar is a particularly difficult one, as can be seen by an examination of the profile prepared by the Township Engineer, Peter S. Gibson. It was



impossible to give in our limited space a profile of the whole line, covering ten miles, but a selection was made of one of the steepest grades, that near Thornhill. It will be seen by the figures upon the profile that this grade amounts to 8 and 10 per cent. These grades would require (as shown by the above extract from Mr. Worby Beaumont) a hauling power "six times that required on an average nearly level road." It must be remembered, too, that the conveyance which is to run over these immense grades is not an ordinary road carriage carrying from one to four people, but is a passenger and parcels van, seated for 25 persons, in addition to baggage on the roof. No such van is now running in any part of the world; and it speaks volumes for the courage of the promoters of the Canadian Motor Syndicate that they should be prepared to undertake such a task. Mr. Still, however, with an autocar equipped with his engines, capable of 20 horse-power, and being built also to exert this power much beyond the normal rates in times of emergency, is satisfied that the car will be able to surmount them without the slightest difficulty. The two motors, although small, will be placed immediately over or next the axles; every wheel will be a driving wheel, and the aggregate power which will be at the command of the motorman will be equivalent to 2,000 lbs. draw-bar strain—each of the motors being capable of 500 pounds draw-bar strain. This latter is the figure already reached in various tests of the motor with which the small Gladstone carriage is equipped.

It is interesting to note in connection with the name of Mr. St. Germain, the promoter of the Pioneer line of Autocars, that the town of St. Germain in France, about 17 miles from Paris, had the honor of possessing the first railway in France; and true to its traditions, it was also the first to carry out trials of mechanical vehicles for public transport. A company has been formed in that ancient town to start a line of autocars between St. Germain and Ecquevilly, with a prolongation eventually to Nantes. Mr. St. Germain, although past the allotted three-score and ten, has shown great enterprise and enthusiasm in this matter, and is keeping the Canadian public posted constantly as to his proposed autocar service. He has purchased an interest in the Canadian Motor Syndicate, and to show his confidence and good faith in the enterprise, has on deposit the sum of $100,000 to invest in the autocar business.

The president of the Canadian Motor Syndicate is Thomas Bengough, court stenographer, Toronto; the mechanical engineer is W. J. Still, and the secretary is L. W. Dorling. At present writing, the business is being rapidly developed, patents having been applied for in all countries of the world covering the inventions of Mr. Still, and negotiations are in progress for increased factory accommodation.

CANADIAN ASSOCIATIONOF STATIONARY ENGINEERS.

On March 8th, Inspector St. John, of the Boiler Inspection and Insurance Company, delivered an interesting and instructive lecture before the Toronto No. 1 C.A.S.E., on the strength of materials in boilers.

The regular meeting of Toronto No. 1, Wednesday, March 16th, was one of the best held this winter. The question box was full, and Bros. Fox, Barman, Mosely and Wickens took part in answering in a very full and instructive manner.

The Hamilton branch of the C.A.S.E. held an open meeting recently in their hall. Quite a large number of the members attended and although through some misconception no regular paper was read some very interesting questions dealing with boilers, engines, machinery, etc, were discussed. In answer to one question as to whether more fuel is used in running two small engines instead of one large one, it has been proved that a large engine of, say, 150 horse-power uses considerably less fuel than two of 75 horse-power. This is owing principally to the fact that more heat is carried off in radiation in using the two than in the one. In cases of electric light plants, power houses, etc., it is often desirable to have two small engines instead of a large one, so that if anything happens to one the power need not be stopped as they will have the other to fall back on. The annual banquet of the Hamilton branch will be held in April.

At a meeting of the London branch C.A.S.E., held in Sherwood Hall recently, a lengthy discussion took place on Electric Motors and Steam Boilers, in which all members took part. Some time ago a pamphlet was issued by the examining board, Messrs. Risler, Bright, Goldart and McLean, with a number of engineering questions to be solved. Two prizes were offered for the best answered paper. D. J Campbell was awarded first prize, $8, and D. McKinley second, $5.

Industrial Notes.

YARMOUTH, N.S., is to have a $12,000 school building.

THE village of Hintonburg, a suburb of Ottawa, is to have waterworks.

M. MOORE, Chatham, Ont, purposes to start a canning factory in Berlin, Ont.

A LARGE saw mill is to be erected at Tusket Wedge, N.S., by J. H. Pothier & Co.

TENDERS are being asked for the building of a waterworks system in Port Colborne.

ST. PATRICK'S CHURCH, Ottawa, Ont., is to be improved this year at a cost of $50,000.

PLANS are being prepared for a new Y.M.C A. building at Winnipeg to cost $50,000.

THE Guelph, Ont., Foundry Co has been organized to manufacture hot air furnaces.

WM. MCKENZIE, Toronto, has become a director of the Calcium Carbide Co., St. Catharines.

A MONTREALER interested in the iron trade is negotiating to buy the Kingston Locomotive Works.

A BUILDING permit has been taken out for a brick addition to the Greening Wire Works, Hamilton.

M. BEATTY & SONS shipped two hoisting engines to Ryan & MacDonald, Dominique, Que., recently.

CITY ENGINEER BARROW, Hamilton, Ont., has planned an $18,000 trunk sewer, to be built this summer.

THE Canadian Typograph Co., Windsor, Ont., has shipped 400 bicycles to South Africa this season.

G. BROWN, Westmeath, Ont., is building the bridge across Coulonge River, near Coulonge, Que., at $6,000.

AT the annual meeting of the Belleville, Ont., Gas Co, on the 12th ult., J. W. Johnson was elected president.

I. USHER & SONS are putting in a new one hundred horse-power engine in their cement mills, at Queenston, Ont.

THE filters installed in the Renfrew, Ont., water-works by J. McDougall, Montreal, have been successfully tested

THE Wm English Canoe Company, Peterborough, Ont., shipped twenty-four canoes to the Yukon in one week recently.

T. L. WILLSON, of the Calcium Carbide Co., Merritton, Ont., will, it is said, build large works near Montmorency, Que.

BLONDE BROS., Chatham, Ont., will build the Kent County House of Refuge at their tender of $14,421 for the building complete.

THE Columbia Handle Company, Thamesville, Ont, has moved its plant to London, Ont., and is located in the old London East G.T R freight sheds.

THE Massey-Harris Co., Limited, Brantford, Ont., will spend $25,000 on enlargement of their works, and will also greatly enlarge the Toronto factories.

THE Hamilton, Ont., Blast Furnace Company during the past winter took three thousand tons of iron ore from the township of Darling, Lanark county, Ont.

FREE instruction will in future be given in sheet metal pattern cutting in the rooms of the Sheet Metal Workers' Union, Toronto. All sheet metal workers of the city are invited to attend.

J. L. GOODHUE & Co., belt manufacturers, Danville, Que, are completing a number of large belts for a new mill on the Pacific coast, consisting of one 48 feet double, two 20 feet double, two 18 feet double and the smaller belts required.

ARTHUR DENISON, architect, Toronto, has taken out a permit, on behalf of the Cawthra estate, for the erection of a $50,000 store building, to be erected according to his plans on the old John Eaton Co 's site, corner of Yonge and Temperance streets, Toronto.

E. GOFF PENNY, R. Prefontaine, J. A. C. Madore, Montreal; N. A. Belcourt and F. McDougall, Ottawa, are applying for a Dominion charter as the Canadian Agricultural Utilization of Sewage Water Company, Ltd., having its chief place of business in Montreal, with a capital stock of fifty thousand dollars.

AN important students' organization came into existence at a recent meeting of the students of engineering at McGill University. It is the Applied Science Technical Society of McGill University. The special importance of the organization is that it will unite together not only the students at college but the graduates of the faculty.

D. McGillivray, Fort Steele, B C., has received the contract for the bridge work on the Crow's Nest Pass Railway from Crow's Nest Lake to Moyie Lake, 200 miles.

Goldie & McCulloch, Galt, Ont., shipped recently six carloads of sawmill machinery, including six boilers, for the Crow's Nest Pass Railway Construction companies.

A company will build a charcoal iron smelter in Deseronto, Ont., on condition that the Rathbun Co. take 25 per cent. of the output, and that the town gives a bonus of $25,000.

An acetylene gas generator exploded in a house in Oshawa recently, doing damage. The machine was blown to pieces, the top being blown upward, making a hole through the ceiling.

The molders at the Waterloo Manufacturing Co.'s foundry have gone out on strike, there being a difference between the manager and the molders regarding what the latter considered a fair day's pay.

The Tisdale property, Brantford, Ont., which has been vacant for several years, will be occupied by the Chalcroft Screw Company, which will be engaged in the manufacture of screws, nuts and bolts.

J. Stuart, foundryman, St. Catharines, Ont., recently cast what is said to be the largest bevel gear ever cast in one piece in Canada. It will weigh four tons; the gear will be used in the Riordon Paper Mills.

At the annual meeting of the Hamilton Iron Mining Company, John Milne was re-elected president, and the old board of directors was also re-elected. The company declared a dividend of 6 per cent. on the year's business.

The New Glasgow Steel Works may go to South Bar, C.B. It is stated that the Dominion Coal Co. are favorable to the erection of the works there, and that they are offering the Victoria pier at a very small sum, and free coal for a certain time.

The Goold, Shapley & Muir Company, Brantford, Ont., who recently had their factory destroyed by fire, have decided to stay in Brantford. The city council has given them the old Verity building for twenty years at a nominal rental of one dollar per year.

Robert Brick, who has been in charge of the tool-making department of the Canada Screw Works, Hamilton, for about a year and a-half, has gone to Vancouver, where he has secured a good position with the Automatic Can Company.

The Portland Rolling Mills Company, Limited, at the annual meeting elected the following board of directors, viz.; J. C. Robertson, president; S. Hayward, vice-president; James Mowat, sec.-treas.; Joseph A. Likely, W. H. Murray, and George F. Baird.

The Bushnell Oil Company are bringing in the machinery of their Petrolia, Ont, refinery to Sarnia. The Petrolia premises will hereafter be used only as a receiving station. The Bushnell Company is having a large number of underground tanks put down on its property in Sarnia.

J. Allison, W. H. Murray, T. McAvity, G. F. Baird, G. S. Cushing, G. McKean and James Fleming, Saint John, N.B., are applying for a New Brunswick charter as the Cushing Sulphite Fibre Company, Limited, chief place of business, Fairville, N.B; capital, $50,000.

St Thomas is to have a brass foundry, which will be established by the Messrs. Jewett, fonndrymen, of Buffalo, N.Y., who have made arrangements to supply the Michigan Central, the Wabash and the Grand Trunk Railways with all the brass fittings they require, and will also do a general business.

At a recent meeting of the Quebec Bridge Company, Mayor Parent reported that the statutory capital of the company, $200,000, was now more than fully subscribed, that the borings in the bed of the river were progressing satisfactorily and the bridge plans had been approved by the chief departmental engineer at Ottawa.

Vincent & Dufresne, civil engineers, St. James Street, Montreal, have a contract for a light portable dredging plant, to be equipped with engines to be run by acetylene gas. Builders of generators for this gas, and makers of suitable engines, should communicate with above firm at once. The experiment will be an interesting one, and the results will be carefully watched for.

The seekers after the treasure buried at Oak Island, N.S., are making progress. They are now sinking a shaft to be used as a pumping shaft, and when a depth of 180 feet is reached they will set up pumps and drive a tunnel toward the drain that leads into the "money pit" from the shore and takes the water out by way of the new pit. While sinking this pit they were doing some prospecting with a drill, and struck iron at 125 ft., 126 ft., 152 ft., 165 ft. and 170 ft. At the 153 feet depth they went through an oak box full of metal of some kind and brought up from it a small piece of parchment. This box is bedded in a cement analyzed and found to be composed of lime and sand.

J. R. Booth, Ottawa, will build a 300 barrel flour mill in Ottawa.

A. Gagnon, Victoriaville, Que., is adding one of the Jenckes Machine Co.'s standard boilers to his equipment.

The Dominion Paper Co, Kingsey Falls, Que., is setting up a new wet machine, one of the Jenckes Machine Co.'s standard 72-inch wet presses, shipped them a week or two ago.

A F. Bury Austin, Montreal, has secured the contract to supply all the dimension timber, white pine and hemlock, for both the understructure and bridge flooring of the new interprovincial bridge at Ottawa.

Joseph Guilbert, of Windsor Mills, Que., is making extensive additions to his saw mill, and has placed an order with the Jenckes Machine Co., Sherbrooke, for a large quantity of shafting, log-handling apparatus, etc.

W. W. Lee Chance, architect, Hamilton, Ont., has prepared plans for a steel frame canning and evaporating building for J. W. Van Dyke, Grimsby, Ont. The building will be 45 x 160 ft., without columns, and two stories high.

Incorporation has been granted to W. C. Fox, T. H. Graham, E. Buffum, F. G. Bowers, D. G. Lorsch, H. B. Latimer and J. R. Shaw, Toronto, as the Frontenac Lead Mining and Smelting Company, Limited; capital, $55,000.

The correspondence system of education in technical subjects, as carried on by the International Correspondence Schools, of Scranton, Pa., is one of the most successful plans ever devised for giving thorough, practical education to wage earners.

The Jenckes Machine Co., Sherbrooke, Que., is furnishing the Canadian Rand Drill Co. with a handsome compound Corliss air compressor weighing some 33 tons, together with accompanying apparatus, bringing the total weight nearly up to 40 tons.

Steps are being taken by T. L. Willson, president of the Calcium Carbide Company, to enter an appeal against the judgment of Magistrate Hall, convicting his men of a breach of the Lord's Day Act in the recent trial for working on Sunday, as mentioned in our last issue.

City Engineer Barrow, of Hamilton, has recently made some interesting experiments in sewage filtration on the lines laid down in different numbers of The Canadian Engineer. One of his experiments which was very successful was made with slack coal as a filtrate.

William McVicar, McVicar, Ont., is putting in a Dake Steam Feed, built by the Jenckes Machine Co., Sherbrooke, Que., with whom the Phelps Machine Co., of Eastman, Que., formerly Canadian manufacturers of the Dake engine, has amalgamated.

The Dominion Radiator Co. is being incorporated to take over the business of the Toronto Radiator Manufacturing Co.; capital, $300,000; directors are as follows:—Jos. Wright, D. Carlyle, J. Stark, J. M. Taylor and C. T. Stark, Toronto.

Incorporation has been granted to the Tree Rotary Engine Company, of Woodstock, Limited, to manufacture and sell Tree's Rotary Engine, and, for the said purpose, to acquire Dominion of Canada letters patent number 55,616 and number 56,806; capital, $24,000.

The waterworks system of Barrie, Ont., has been valued for arbitration purposes by E. Vanier, C.E., Montreal, at about $110,000, and by Willis Chipman, C.E., at $53,770; and E. H. Keating, C.E., Toronto, at $52,369. These figures are the estimated cost, less the speculative depreciation in seven years.

Galt, Ont., manufacturers are enlarging their establishments this year. The Goldie-McCulloch Co. is erecting new offices and intends to add to its present molding shop. The R. McDougall Co. Limited, is also contemplating extensive improvements to its foundry, and the C. Turnbull Co. will put up a mill on the site of the W. S. McKay factory.

The Royal Paper Mills Co. has recently added a complete rope drive to the transmission machinery at the East Angus, Que., mill. This was furnished by the Jenckes Machine Co., Sherbrooke, which is furnishing the entire tank work, together with the accompanying machinery. East Angus presents a scene of great activity, carload after carload of material arriving and being placed in position. When completed, this mill will take a prominent place among the producers in the pulp and paper trade.

THE PUBLISHERS.

WILLIS CHIPMAN, C.E., has made a report to the London, Ont., city council, favoring the establishment of a sewage farm instead of running the sewage into the river as at present.

CITY ENGINEER MITCHELL, of Niagara Falls, Ont., has made a survey of the Niagara River bank both at the top of the cliff and the water's edge between the cantilever bridge and the whirlpool, for the park commissioners, who are preparing preliminary surveys of the water power facilities at the rapids.

Railway Matters.

F. B. WADE, Bridgewater, N.S., is applying for a charter to build a railway from Shelburne to Halifax.

THE Pennsylvania Steel Co., Harrisburg, Pa., will build sixteen bridges for the Grand Trunk this summer.

THE plans have been prepared for the new C.P.R. shops at Revelstoke, to which place the shops at Donald will be removed.

THE C.P.R. will build a new depot at Vancouver, B.C. This with wharves and other buildings, entail $300,000 expenditure.

ALEXANDER MCGREGOR has been sent out by the Dominion Atlantic Railway Company of London, Eng., to act as superintendent at Yarmouth, N.S.

F. R. F. BROWN, mechanical superintendent of the Intercolonial Railway, has been removed from his position and will, it is understood, open an office in Montreal as a consulting engineer.

THE Canadian Pacific Railway has done such a large grain business from St. John, N.B , this season that it has been decided to build another elevator there, and the plans are being got ready for a new one, which will be of 800,000 bushels capacity.

DR. KING, vice-president, and Superintendent Woollat, of the Lake Erie and Detroit River Railway, have made a trip over the proposed extension of the L. E. & D. R. R. from Ridgetown to St. Thomas, Ont. The latter town will probably give a bonus of $20,000 to the extension.

THE Canada Atlantic Railway Company is applying for power to construct an extension from some point on the line of the company on or near the River Richelieu, in the county of Missisquoi, in an easterly direction to a point on the international boundary line in the county of Missisquoi, or in the counties of Brome, Stanstead or Compton, so as to form a connection with the railway systems of the United States, and also from some point on present line near the St. Lawrence River or north-westerly therefrom, through the counties of Soulanges and Vaudreuil, crossing the Ottawa River near the Village of St. Anne, and to some point in the City of Montreal, by the most feasible route to the St. Lawrence River, at some point in or below the said city.

THE report of the Grand Trunk shows the net revenue surplus for the half year ending December to be £275,263, being an increase of £236,117 over the corresponding period last year. Passenger earnings decreased £151,728, compared with 1896. The tons of freight and live stock have increased 410,960. The earnings per train mile have increased fourteen cents, and the working expenses have decreased nearly seven per cent. The Chicago and Grand Trunk shows a deficit of £49.467, being £17.900 better than in 1896. The Detroit and Grand Haven shows an increase in net revenue of £21,373, leaving a net deficit of £2,174 on revenue charges. The directors report the agreement granting the Wabash Company joint use for 21 years of that portion of the Grand Trunk between Windsor and Black Rock station.

THE Governor of Newfoundland, Sir Herbert Murray, has signed a railway contract with R. G. Reid of Montreal. The Government claims that the arrangement will effect a saving of $80,000 a year in addition to promoting the development of the country. Mr. Reid has contracted to build a railway across the island and to work the entire railway system of 650 miles for 50 years. receiving a subsidy of 2,500 acres of land per mile. He pays $1,000,000 now, which will become $7,000,000 at the end of the period, when the colony takes the money and the contractors will take the railway. If he should make default in carrying out the contract during the period, both the money and the railway are forfeited to the colony. Mr. Reid purchases St. John's dock for $350,000, and the Government telegraph lines for $125,000. He also undertakes to build seven mail steamers to ply in the Great Bays, receiving a subsidy of $100,000 for thirty years. The contractor secures also certain coal areas which he agrees to work, as also pulp and lumber mills and copper and other minerals, being protected by a dollar duty to be imposed on imported coal. Furthermore he contracts to build an electric railway in St. John's, and tc pave the main streets of the city for $140,000.

THE management of the Grand Trunk Railway system has contracted with the Pullman Company, Chicago, for the construction of twenty first-class passenger coaches. They will be turned out with every modern improvement. The Grand Trunk is just finishing the construction of two hundred freight cars, and have decided to build three hundred coal cars in their Canadian shops. In addition, ten new locomotives have been received from the Baldwin Works, and ten more are coming from the Schenectady Works. The C.P.R. is also making the addition of some fifty-five cars to the already large supply used by the great Canadian trans-continental line. Ten of them will be sleeping cars, twenty of them first-class passenger coaches, ten tourist cars and five baggage cars. All, except the tourist cars, are being built at the company's shops, Niagara Falls, Ont., the Crossen Works at Cobourg having the contract for the tourist cars.

MOVING TIME!! Subscribers are reminded to notify us of any change in address necessary. Give both old and new addresses.

THE PUBLISHERS.

Electric Flashes.

W. MOORE & SONS have renewed their lighting contract with Meaford, Ont.

THE Perth, Ont., Waterworks Co. is installing two phase "S.K.C." motors.

THE Montreal Street Railway Co. has received an order for 20 motor cars from Kingston, Jamaica.

C. FRASER has succeeded Electrician Brown in office at the H., G. & B. power-house, at Stoney Creek, Ont.

ARKONA is said to be willing to give a $10,000 bonus to the proposed electric railway from London to Lake Huron.

PETERBOROUGH, ONT., is discussing a bonus of $1,000 a year for 20 years for a radial railway taking in the lake district.

HENRY MORGAN & Co., Montreal, have placed an order with the Royal Electric Co. for a 20 K.W. direct current generator.

THE Brantford, Ont., Electric and Operating Co. is installing a 60 K.W. " S.K.C. and a 40-light T-H Arc machine received from the Royal Electric Co.

IT is reported that the Quebec Electric Street Railway will extend its line from the city to Cap Rouge via the St. Louis road, and returning by the St. Foye road.

ARRANGEMENTS have been completed by which the extension of the lines of the Montreal Street Railway into the village of Verdun, are assured for the coming summer.

OWING to ill-health, John McDermott, who has been in charge of the Almonte Electric Light Company since it was formed, has retired from active work.

NEGOTIATIONS have been commenced with a view to construct an electric railway between L'Epiphanie and Joliette, Que., passing through the parish of St. Jacques de L'Achigan.

THE projectors of the Hamilton, Chedoke & Ancaster Radial Electric Railway, propose to extend it to Brantford, and are vigorously pressing the matter with the municipalities most concerned.

W. J. FLETCHER, Markham, Ont., proprietor of the electric light plant there which was recently destroyed by fire, has decided to reconstruct the plant, and has purchased from the Royal Electric Co. a 20 K W. " S.K.C." generator.

LAST year the Galt, Preston and Hespeler Railway carried 221,647 passengers, an increase of 2,027. The total freight carried was 12,973 tons, an increase of 4,663 tons. The increased earnings was $1,900. President Todd has been re-elected.

THE C.P.R. management is experimenting with a system of electric light generated from the axles of moving cars, and the results are said to be very promising. Storage batteries are used. · The " Winchester " is the first with the new electric system.

THE long-standing litigation over the assessment of the poles, wires and tracks of the Toronto Railway Company has been settled by the Court of Appeal giving judgment in favor of the city of Toronto. By the decision, the assessment of $452,277 against the company in Wards two to six is confirmed for 1898, which will probably yield between $7,000 and $8,000 in taxes.

TORONTO and Hamilton, Ont., are both agitating the question of municipal lighting plants. Tenders will, probably, be called for in each case; but only in order to determine prices for purposes of argument.

THE Shipton Electric Light and Power Co., Danville, Que., has received a Crocker Turbine from the Jenckes Machine Co., Sherbrooke, which is proceeding with the installation of the same with penstock and draft tube.

THE report of the U.S. commissioner of patents for the year 1897 shows that to residents of foreign countries the number of patents issued were: England, 706; Canada, 286; Germany, 551, and France, 222. The most noted are those connected with the development of electrical inventions.

T. E. MCLELAN, the courteous and obliging manager of the Berlin and Waterloo, Ont., Street Railway, has resigned his position to go to the Klondyke. He will be succeeded by H. H. Hilborn, E.E., of Montreal, who, since his graduation from Cornell, has been in the service of the Montreal Street Railway Co.

THE Halifax Electric Tramway Company, Limited, has just installed two large generators, each having a capacity of 6,000 sixteen-candle power lamps, which, together with generators previously operating, make the capacity of the company 18,000 sixteen-candle power lamps. There is no ground, the company states, for the rumor of the amalgamation of the company with the People's Heat and Light Company.

THE transfer of the Quebec District Railway from the present company to the new one formed by H. J. Beemer, will take place before July 1st. New open cars for summer use have been already ordered. Meanwhile the changing of the steam system to electricity on the line of the Quebec, Montmorency and Charlevoix Railway will be proceeded with. Most of the cars now in use upon the road will be run as electric cars with one, two or three trailers, as necessity may arise. It is the intention to run electric trains to Ste. Anne about every hour. About the whole amount of the capital stock of the new Quebec Electric Railway Company has been underwritten.

Personal.

MORGAN BALDWIN, harbor master, Toronto, died last month at his residence in that city.

THEO. ZWICKER, machinist, has now charge of the machine shop at the Halifax dry dock.

S. S. FOLEY, Chapleau, Ont., has been appointed despatcher on the Crow's Nest Pass Railway.

ED. S. FRASER, C.E., New Glasgow, N.S., has taken a position on the staff of the South Shore Railway.

JAS. W. MILNE, formerly of the Waterous Engine Works Co., Brantford, Ont., has gone to Vancouver, where he will represent a Montreal firm.

ENGINEER HUTCHINSON of the G.T.R., who was badly burned in the railway accident at Burlington, Ont.. died at the Hamilton Hospital, March 4th.

ARCHITECT ADAMS, of the Kingston Penitentiary, has been suspended from duty on a charge of insubordination preferred by Deputy Warden O'Leary.

H. GARDNER SMITH, the new engineer of the D.A.R. steamer "Prince Edward," has arrived at Yarmouth, N.S., from England and entered upon his duties.

R. G. MCCONNELL, of the Dominion Geological Survey, has accepted the position of mineralogist of the Province of British Columbia, to succeed W. A. Carlyle, who resigned.

THE death occurred at Truro, N.S., last month, of Wm. Yould, sr., assistant trackmaster of the I.C.R., aged 78 years. He was the first foreman of tracklaying on the Nova Scotia Railway, now a part of the I.C.R.

RAOUL RINFRET, C.E., of Montreal, who is going to the Yukon with the Slavin-Boyle party, has been commissioned by Minister Sifton to organize a meteorological service in the Yukon country, as well as to make certain surveys for the Interior Department.

THE well-known contractor, John Ross, died very suddenly at Lancaster, Ont., March 12th. He was very successful as a railway contractor, and very wealthy. It is said of him that he built more miles of railway than any other contractor in America. He was 78 years of age.

ALBERT ROBINSON, formerly of Crowe's Iron Works, Guelph, Ont., and lately of Detroit, has been made foreman of the Cossitt Works, Brockville, Ont.

JOHN GALBRAITH died recently in Brantford, Ont., from blood poisoning. Deceased had been employed for the past ten years as boiler-maker at the Waterous engine works. A few weeks ago he got his foot badly bruised with a heavy piece of iron, from the effects of which blood poisoning set in.

JAMES M. MACOUN, who has interested himself in the Behring Sea investigation for some years, has, in recognition of his services been appointed by the Government assistant naturalist of the Geological Survey. He has been on the temporary staff of the Geological Survey since 1883.

THE death of W. M. Hamilton, recently, removes an old resident of Toronto. Mr. Hamilton had been for the last year manager of the St. Lawrence Foundry, but from 1885 to 1893 he was superintendent of the Parkdale Waterworks Department, but resigned when it was amalgamated with the city.

SIR HENRY BESSEMER, the celebrated inventor of Bessemer steel, died in London, March 15th. Deceased was an eminent engineer, born in Hertfordshire, England, in 1813, he early devoted himself to the improvement of machinery, and acquired celebrity by his invention of a new practical process for the manufacture of steel, which was extensively adopted in Europe and America, and the product of which is known in trade as Bessemer steel.

CECIL B. SMITH, Ma.E., A.M., Mem. Can. S.C.E., who has just resigned his post at McGill, to take a position on the engineering staff of the C.P.R., was born at Winona, near Hamilton, March, 1865, and received his education at the Hamilton Collegiate Institute, and afterwards in civil engineering at McGill University, graduating in 1884 with first honors and the Governor-General's medal. Since that time he has been engaged chiefly on railroads, although working for a short time under Mr. Thomas Monro on the Welland Canal, and under Mr. John Kennedy on the Montreal Harbor Commission. He has had charge of many heavy pieces of construction; on the Northern and Pacific Junction Railway under Mr. J. C. Bailey, on the St. Catharines and Niagara Central Railway under Mr. B. N. Molesworth, on the C.P.R. at London, Ont., under Mr. W. T. Jennings; surveyed for the Toronto, Hamilton and Buffalo Railway during the summer of 1889, under Mr. A. L. Hogg. He was then appointed successively: resident engineer, chief draughtsman and division engineer on the C.C. and C.R.R. in Tennessee and S.C. under Mr. A. N. Molesworth, constructing 70 miles in all. He was then appointed division engineer on the Roanoke and Southern Railway, under Mr. Andrew Onderdonk, in charge of 65 miles of heavy work, including track-laying and maintenance. On this being completed, after short reconaissances for the Concord Southern Railway, he was appointed resident engineer on the Baltimore and Ohio Railway, under Mr. W. T. Manning, in charge of 14 miles of very heavy work. On completion, he was appointed Lecturer in Civil Engineering and Descriptive Geometry at McGill University, the duties of the former being to lecture in railway engineering and on testing of materials of construction. In 1888 he was made associate M.C.S.C.E., and in 1894 obtained the degree of Master of Engineering from McGill University. On the occasion of his resignation from the faculty of applied science, McGill University, Professor Smith was the recipient of a beautifully engraved walnut case containing two very valuable aneroid barometers, with kindest expressions of regard and regrets at his withdrawal from the university, on behalf of the undergraduates of 1898 and 1899 of the faculty of applied science. The interesting series of papers from Mr. Smith's pen which have appeared in the CANADIAN ENGINEER during the past year will be continued in next year's volume. The articles which have already appeared are now ready to be issued in book form as "Railway Engineering," Vol. I.

Marine News.

Edwardsburg Starch Co., Cardinal, Ont.: Steamer—Rosedale, Capt. Jas. Ewart, Engineer E. O'Dell.

Myles' Sons, Thomas, Hamilton, Ont.: Steamer—Myles. Capt. John S. Moore, Engineer Jas. Smeaton.

Sylvester Bros., Toronto, Ont.: Steamer—Eurydice, Capt. J. Jackson, Engineer Alex. Munro. Schooner—St. Louis, Capt. Geo. Williamson.

Tuttle; Jessie Hall, Capt. C. Martin, Engineer Alex. Barton; J. A. Walker, Capt. John Boyd, Engineer Geo. Boyd; D. G. Thomson, Capt. Jas. Murray, Engineer G. Henderson. Lake barges—Kildonan, Capt. Maxime Lefebvre; Minnedosa, Capt. R. C. Irwin; Selkirk, Capt. H. Colvin; Winnipeg, Capt. James Kirkwood; Melrose, Capt. James Fleming; Dunmore, Capt. John Phillips. River barges—Alberta, Capt. Frank Poirier; Acadia, Capt. Louis Hebert; Bella, Capt. Peter Lalonde; Cleveland, Capt. J. D. Parron; Chicago, Capt. Arsene Charlebois, sr.; Colborne, Capt. Ben. Sauvie; Corn Crib, Capt. A. Charlebois, jr.; Cornwall, Capt. H. Boyer; Detroit, Capt. Treffle Davust; Dorchester, Capt. Jules Lalonde; Eagle, Capt. A. Monnette, Jr.; Hector, Capt. Tim Hebert; Glengarry, Capt. Albert Major; Harvest, Capt. John Bradley, Jr.; Iowa, Capt. Jos. Davust; Jennie, Capt. Moise Moreau; John Gaskin, Capt. Theo. Leduc; Lancaster, Capt. Jos. Page; McCarthy, Capt. E. R. Roy; Montreal, Capt. M. Lefebvre; Maggie, Capt. A. Monnette; Nebraska, Capt. Celestia Leboeuf; Regina, Capt. Ovide Trudell; Senator, Capt. Alfred Lalonde; Star, Capt. E. Secotte; Toledo, Capt. Fred Leduc; Toronto, Capt. A. Levoie; Wheat Bin, Capt. A. St. Marcelles; Cobourg, Capt. Frank Lafrance; Brighton, Capt. N. Mallette; Kingston, Capt. Alex. Hebert.

For Sale Cheap

A New 100 Kilowatt 125 Volt Multipolar, Direct Current Dynamo

Latest steel frame type, with iron clad armature.

A most complete set of Station Attachments. Suitable for Incandescent Lighting, with a capacity of 2,000 16-candle power lamps, or for power or electro-chemical purposes; has never been used only for a test.

For particulars apply to E. H. HILBORN, 74 Brunswick Avenue, Toronto, or to JOHN TOLMIE, Kincardine.

The Ontario People's Salt and Soda Company, Limited

The OTTAWA PORCELAIN & CARBON CO., Limited, Ottawa, Ont.

MANUFACTURERS OF

Carbon Points for all kinds of Arc Lamps, including cored and solid carbon for incandescent circuits.

Also Motor Brushes and Specialties in Carbon for Telegraph, Telephone and Electric Light Supplies. Porcelain Insulators, Cleats, Door Knobs, and all kinds of Pressed Porcelain for Electrical and Hardware Lines.

All Goods Guaranteed to give Satisfaction

MINERAL PRODUCTION OF CANADA.

The following summary of the mineral production of Canada in 1897 has been issued by the Geological Survey Department, and is subject to revision in a later bulletin :

Product.	Quantity. (a)	Value (a)
METALLIC.		
Copper (fine, in ore, etc.) (b) ....lbs.	13,300,802	1,501,660
Gold	.....	6,190,000
Iron ore ....tons.	71,451	178,716
Lead (fine, in ore, etc.) (c) ....lbs.	39,018,219	1,396,853
Mercury .... "	688	324
Nickel (fine, in ore, etc.) (d) .... "	3,997,647	1,399,176
Platinum	.....	6,600
Silver (fine, in ore, etc.) (e) ....ozs.	5,558,446	3,322 905
Total metallic	.....	13,996,234
NON-METALLIC.		
Asbestos and asbestic ....tons.	25,262	324,700
Chromite .... "	2,637	32,474
Coal .... "	3,876,201	7,286,257
Coke (f) .... "	78,811	209,920
Felspar .... "	1,275	3,506
Fire clay .... "	1,923	5,759
*Grindstones .... "	.....	40,000
Gypsum .... "	239,691	244,531
*Limestone for flux .... "	.....	40,000
*Mica	.....	75,000
Mineral pigments—		
Baryta....tons.	571	3,060
Ochres .... "	3,905	23,560
*Mineral water ....galls.	.....	140,000
Molding sand....tons.	5,485	10,931
Natural gas (g)	.....	325,873
Petroleum (h)....bbls.	709,857	1,011,546
Phosphate (apatite) ....tons.	908	3,984
Pyrites .... "	38.910	116,730
*Salt .... "	.....	190,000
Sundry minerals, partly estimated, including actinolite, graphite, manganese, soapstone and tripolite	.....	10,000
STRUCTURAL MATERIALS AND CLAY PRODUCTS.		
Cement, natural ....bbls.	85,450	65,893
" Portland .... "	119,763	209,380
Flagstones	.....	7,190
*Granite	.....	75,000
*Pottery	.....	125,000
Sewer pipe	.....	164,250
Slate	.....	42,800
Terra-cotta	.....	155,595
Building material, including bricks, building stone, lime, sands and gravels and tiles (estimated as for previous year)	.....	3,600,000
Total structural materials and clay products....	.....	4,445,108
All other non-metallic	.....	10,097,831
Total non-metallic....	.....	$14,542,939
Total metallic....	.....	13,996,234
Estimated value of mineral products not returned	.....	250,000
1897, Total....	.....	$28,789,173
1896 "	.....	22,609,825
1895 "	.....	20,715,319
1894 "	.....	19,933,857
1893 "	.....	20,035,082
1892 "	.....	16 628,417
1891 "	.....	18,976,616
1890 "	.....	16,763,353
1889 "	.....	14,013,913
1888 "	.....	12 479,550
1887 "	.....	11,365,705
1886 "	.....	10,221,255

*Partly estimated.

(a) Quantity or value of product marketed. The ton used is that of 2,000 lbs.

(b) Copper contents of ore, matte, etc., at 11.29 cents per lb.

(c) Lead contents of ores, etc., at 3.58 cents per lb.

(d) Nickel contents of ore, matte, etc., at 35 cents per lb.

(e) Silver contents of ore at 59.79 cents per oz.

(f) Oven coke, all the production of Nova Scotia and British Columbia.

(g) Gross return from sale of gas.

(h) Calculated from inspection returns at 100 galls. crude to 42 refined oil, and computed at $1.42½ per bbl. of 35 imp. galls. The barrel of refined oil is assumed to contain 42 imp. galls.

The following table shows the principal changes in production and values for the calendar year 1897, as compared with the figures given in the revised summary for 1896 :

PRODUCT.	Quantity. Increase. p.c.	Quantity. Decrease. p.c.	Value. Increase. p.c.	Value. Decrease. p.c.
Metallic—				
Copper	41·6	.....	46·9	.....
Gold	.....	.....	122·6	.....
Iron ore	.....	22·3	.....	6·7
Lead	61·2	.....	93·7	.....
Nickel	17·7	.....	17·7	.....
Silver	73·4	.....	54·6	.....
Non-Metallic—

Cement	37·6	.....	36·5	.....

The increase in the items silver and lead is practically all to be credited to British Columbia, to which province is also largely due the increase in the production of copper. The largest increase in this latter metal is, however, due to the increased shipments of nickel-copper mattes from the Sudbury mines in Ontario. The third copper producing province, Quebec, also contributed a fair amount to the increase shown. The silver, copper and lead increases as far as British Columbia is concerned, represent the largely extended activities in the South Kootenay districts of Slocan, Nelson and Trail Creek.

The most significant item, however, is to be found in the increase of nearly 123 per cent. in the gold. All the gold producing districts of the Dominion show gratifying increases, although by far the largest part is due to the discoveries of rich placer mines in the Yukon country, and to the increased output of Trail Creek and other districts in British Columbia. The former increase amounted to about 2¼ millions and the latter to nearly $1,000,000.

The remaining metal of importance is nickel, which is seen to have shown an increase of nearly 18 per cent. As in the past this is all from the Sudbury district.

Thus the aggregate result of the increases in the metallic productions is nearly $6,000,000, or a proportion of about 74 per cent.

An interesting result of the mining developments and discovery of 1897 is shown in the increase in the proportion of the value of the total mineral production to be credited to the metals. In 1896 these constituted about 36 per cent., whilst in 1897 this proportion was increased to nearly 49 per cent.

Turning to the non-metallic products, we find that as far as the data at present available permit of a conclusion being arrived at, the total value shows under 2 per cent. of an increase over that of the previous year. The only considerable change to be noted is that given under the heading asbestos, where the quantity has more than doubled, whilst the value has fallen off almost 25 per cent. This is due to the fact that the output of the new by-product, asbestic, is included. This constitutes over half the weight of the whole, but being a low-priced article brings down the price per unit very much. The returns, however, show also a falling off in the prices of the usual grades of the mineral apart from the above influence.

In the important mineral coal the variation is but little. The falling off in the production of the higher priced mineral of British Columbia and the increase in that of Nova Scotia at a lower price causing a fall in the total value. In gypsum the increase in the value is larger than that shown in the quantity. This is due to the larger proportion of the higher priced product, plaster of Paris, included in the returns for 1897. The lower average price ruling during that year for petroleum caused the decrease in the value of this article to be much greater than in the quantity.

The following table gives the proportional values of the different minerals in the grand total. It is interesting to note the changes in their relative position in 1897, as compared with 1896 :

Product.	1896. Per cent. of Total Production.	Product.	1897. Per cent. of Total Production.
Coal	31·94	Coal	25 31
Building material	15 72	Gold	21·50
Gold	12·30	Building material	12 50
Silver	9 50	Silver	11·54
Nickel	5 25	Copper	5·21
Petroleum	5 11	Nickel	4 86
Copper	4·52	Lead	4·85
Lead	3 20	Petroleum	3·51
Asbestos	1·90	Natural Gas	1 13
Natural Gas	1·22	Asbestos	1 13
Cement	·89	Cement	·95
Iron	·85	Gypsum	·84
Gypsum	·79	Coke	·73
Salt	·75	Salt	·66

ONE-TIME INSERTIONS.

"One-time insertions seldom pay. The publisher knows this as well as does the advertiser who has learned it by sad experience. He should impress this fact on the advertisers from whom he solicits business. There are few periodicals, however, strong enough to resist the temptation to take everything offered them without regard to the advertiser's best interests. The advertiser who has tested it knows that it usually takes several insertions of an ad. to arouse the interest of the readers of a periodical. It is continuous advertising that pays." —*Advertising Experience, Chicago, March, 1898.*

We quite agree with *Advertising Experience* on this point, having knowledge of more than one case in which results have come from advertisements many months after their appearance. Had advertisers judged of the merits of the medium from immediate results, the chances were decidedly against the paper.

The Canadian Engineer

VOL. VI.—No. 1. TORONTO AND MONTREAL, MAY, 1898. PRICE, 10 CENTS $1.00 PER YEAR.

The Canadian Engineer.

ISSUED MONTHLY IN THE INTERESTS OF THE
CIVIL, MECHANICAL, ELECTRICAL, LOCOMOTIVE, STATIONARY, MARINE, MINING AND SANITARY ENGINEER, THE SURVEYOR, THE MANUFACTURER, THE CONTRACTOR AND THE MERCHANT IN THE METAL TRADES.

SUBSCRIPTION—Canada and the United States, $1.00 per year; Great Britain and foreign, 6s. Advertising rates on application.

OFFICES—62 Church Street, Toronto; and Fraser Building, Montreal.

BIGGAR, SAMUEL & CO., Publishers,
E. B. BIGGAR, R. R. SAMUEL
Address—Fraser Building, MONTREAL, QUE.

Toronto Telephone, 1392. Montreal Telephone, 2589.

All business correspondence should be addressed to our Montreal office. Editorial matter, cuts, electros and drawings should be addressed to the Toronto Office, and should be sent whenever possible, by mail, not by express. The publishers do not undertake to pay duty on cuts from abroad. Changes of advertisements should be in our hands not later than the 1st of each month to ensure insertion.

FOR THE CANADIAN ENGINEER.

RAILWAY ENGINEERING.*

BY CECIL B. SMITH, MA. E., MEM. CAN. SOC. C.E., ASSISTANT PROF. OF CIVIL ENGINEERING IN M'GILL UNIVERSITY.

CHAPTER VI.

(Continued from last issue.)

RAILWAY LAW.

Railroads being recognized as public necessities have had great powers conferred on them by legislatures, which have also necessitated many legal restrictions to prevent the abuse of these powers. All of which in Canada has in time become formulated in the "Railway Act." This Act defines, amongst other things necessary for a railway engineer to be familiar with:—

I. The powers conferred on the Railway Committee of the Privy Council for negotiating traffic, tolls, returns, methods of operation, of construction, capital stock, and distribution of gross revenue obtained.

II. The privileges and powers granted to railway companies.

III. The duties of a railway company to the Government and to the Privy Council.

IV. The duties of the railway company to the individual, and the rights of the private individual.

Much of the matter contained is rarely needed by the engineer, and the following extracts cover the main information which he is likely to need in the course of construction and maintenance.

* This series of papers will be issued in book form as soon as they have appeared in THE CANADIAN ENGINEER.

I.—POWERS CONFERRED ON THE RAILWAY COMMITTEE.

(*a*) To regulate the speed through various classes of cities, towns and villages—which is not to exceed six miles per hour in any case.

(*b*) To regulate the use of steam whistles in towns, cities, etc.

(*c*) To regulate the means for passing from one car to another, for the safety of employees, and the methods of coupling cars.

(*d*) To impose fines for offences under these clauses.

(*e*) To enquire into, hear and determine applications, disputes or complaints regarding right of way and location questions, constructing branch lines, the crossing of one railway company's tracks by those of another railway company, the construction of railways along or across highways or navigable waters, tolls, rates, running powers, traffic arrangements, unjust preferences, discontinuations, distortions and the carrying of highways, streets, ditches, sewers, etc., over or across the lands of a railway company.

(*f*) By itself or agents, it has full legal power to enter on to property of a railway company to examine books, plans, etc., to summon witnesses and in general it is to have the same powers as a law court.

(*g*) The inspecting engineers of the Privy Council are to have every desired information, in reason, supplied to them on demand. They are to be carried free while on inspection trips, and to have the services of all company telegraph operators free while on Government business—penalties for obstructions of the inspecting engineers are also defined.

II.—THE PRIVILEGES AND POWERS OF A RAILWAY COMPANY.

These are given with the view of assisting the company in overcoming obstructive measures, of a corporation or individual, where it is evident that the public would be best served by the construction and operation of a railway.

These powers should be thoroughly considered by a company's engineer before taking any steps likely to incur the ill-will of the public, to whom the company must ultimately look for its income.

(*a*) The company or its agent may enter on crown lands or the lands of any person or corporation whatever for the purpose of survey and location.

(*b*) It may purchase land for the use of the railway, and may sell what it does not need.

(*c*) It may build anywhere within one mile of the first located filed line, or within any further distance prescribed by the special Act.

(In the Act a railway is said to be near to another when some part of one is within one mile of some part of the other railway.)

(*d*) It may fell trees within 99 feet of either side of the railway, when they are liable to fall across the track.

(*e*) It may cross or join any other railway, and enter on its lands.

(*f*) It may divert temporarily or permanently streams, highways, water or gas pipes, sewers, drains or telegraph or telephone poles, but must restore them to their former

state, if possible, or put them in a state not materially altering their usefulness. (Note this with reference to keeping them open during the construction of the roadbed.)

(*g*) It may construct, operate and keep in repair its road, together with the accessories commonly belonging to a railway, and may carry traffic and collect tolls, and may, in general, do everything necessary to a successful operation of its enterprise and the accommodation of the public, but in the exercise of these or other powers the company shall do as little damage as possible, and make full compensation for damage done or loss inflicted, in a manner prescribed in the Railway or a special Act.

The essence of these general powers is compensation. It is the limitation of what would otherwise be absolute, arbitrary powers.

II. (*A*) Powers with Limitations.

(*a*) No person who holds a contract for work with a railway company can be a director on its board, nor can a director or officer of a company even go surety for a contractor.

(*b*) The first charges on the income of a railway company are the penalties, if any, arising from this Act. The next are the working expenses of the road, and the third are the bonds—the latter, however, all having equal claims in proportion to remaining assets.

(*c*) The consent of the Governors-in-Council is necessary before Crown or Indian lands can be entered on, and in the case of Crown lands the right of way only, i.e., an easement, is all that can be obtained, and not ownership or full possession.

(*d*) The consent and approval of the Railway Committee must be obtained before possession or use of the land or property of another railway company can be effected.

(*e*) The ordinary amount of land obtainable without the consent of the owner is 99 feet, while exceptions are authorized by the Minister in case of deep cuts or fills and depot grounds, which is in general limited to a tract of land 1,950 feet long by 300 feet wide, but any extent of land may be purchased with the consent of the owner. Extra land is to be shown on the maps or plans filed with the Government.

(*f*) After filing plans (to be afterwards explained) the company may take possession as shown on those plans, and settle afterwards, amicably or by arbitration. This is a very necessary power, for otherwise contractors would be kept off the land for indefinite periods, the progress of the work impeded and a good chance given the contractors for suits for damages caused by delay, or for excuses for slow progress.

(*g*) The company may enter on lands not more than 600 feet from the located line, for purposes of construction or repairs, without consent of the owner, provided a sum of money, fixed by a judge of the Superior Court, is deposited with that court, pending the award for damages.

(*h*) Power of surveying and arbitrating in the usual way is also given whenever the company desire extra land for stone, gravel, water or earth, or on which to construct sidings or branches, or on which to convey water to the company's works.

(*i*) The company may occupy land between 1st November and 1st April, with snow fences, subject always to damages as a court may decide.

(*j*) No lateral deviation of more than one mile shall be made from the original location, except under provisions of a special Act.

(*k*) Error in name or omission of the same from plans and books of reference does not prevent the company from entering on land so affected.

III. Duties of a Railway Company to the Government.

(*a*) On completion of location surveys, plans and books of reference showing all properties asked for, must be forwarded in triplicate to the Minister, who after ten days' notice to all interested parties, hears all counter claims and representations, and the plans, as finally decided on, are signed by the Minister, after which one copy is retained at the department, another is deposited by the company in the office of each municipality affected, while a third one is given into the hands of the company itself. After these proceedings following the action as described in Art. *f*, powers with limitations.

(*b*) All extra widths desired must be shown on the plans filed.

(*c*) Any change from the original plans or profiles must have separate plans, etc., submitted and deposited in the usual way before the alteration can be made.

(*d*) Ten days after plans have been filed in the offices of the municipalities (registry offices) and notice published in a newspaper, a notice may be served on interested parties owning land, giving

(*a*) Description of land required.

(*b*) Amount offered by the company for land or damages.

(*c*) Name of company's arbitrator if offer is not accepted.

Such notice to be accompanied by a sworn statement of a surveyor or engineer (not an arbitrator).

(*a*) That the land is needed as described for the purposes of the railway.

(*b*) That he knows the land, or damages likely to result, from the railway being built and operated.

(*c*) That the sum offered is, in his opinion, fair compensation.

(*e*) Should the offer not be accepted, arbitration is resorted to. This is usually outside the province of the engineer, except in giving evidence and preparing plans, but it may be useful to remember that, in considering the value of land taken or amount of damages done, the increase of values of lands adjacent (*i. e.*, of same plot) not taken by the company, which is created by the construction of the railway, is to be taken into account and offset against damage inflicted.

(*f*) Before a company can unite with or cross over any railway with its roadbed or track, it must submit plans and full details of proposed mode of crossing to the Railway Committee, and give ten days' notice of application to the other company affected. The committee may make such changes or regulations as appear necessary for public safety, and apportion the cost of constructing the necessary works to the different companies, and may also, in case of level crossings, on application of either company, direct such inter-locking signal system or device to be used as, in their opinion, renders it safe for engines to pass over such crossing without coming to a full stop. This clause also applies to electric and other street railways.

(*g*) When the railway is finished, plans and profiles in triplicate of the completed work, showing land taken, names of owners, etc., must be filed as in the original survey or alterations within six months after completion of railway, under penalty of $200 fine per month.

(*h*) The scales of plans and profiles are to be as prescribed by the Minister; they are usually: Plans, 400 feet to one inch; profiles, 400 feet to one inch horizontal: pro-

files, 20 feet to one inch vertical, and are to be all signed by the chief engineer or president of the railway.

(*i*) Within 48 hours at furthest, after any accident has occurred on a railway line, involving personal injury, or the damage or destruction of any structure, the railway company must notify the Minister of the same under $200 per day penalty. And, if necessary, the Privy Council may appoint a commissioner to enquire into the causes, etc., of the same.

(*j*) Annual returns from 1st July to 1st July must be forwarded in duplicate to the Minister within three months after the expiration of such financial year by each railway company, of its capital, traffic, working expenditure, and any other information shown on the blank forms furnished.

(*k*) Weekly returns of traffic shall also be furnished the Government within one month after the period quoted, and a copy of the same must be posted for public view in the head office of the company.

(*l*) Twice a year accidents and casualties must be similarly reported within one month after each six months' period has elapsed, giving, (1) Causes and natures, (2) locality and time of day, (3) extent and particulars.

IV. GENERAL DUTIES OF A RAILWAY COMPANY TO THE PEOPLE AND THE RIGHTS OF INDIVIDUALS.

(*a*) A company may not obstruct the entrance to a mine, open or about to be opened.

(*b*) A company shall not impede navigation in a navigable river.

(*c*) In constructing drawbridges, bridge-piers or wharves, the manner of construction as it affects navigable waters shall be fully and entirely decided upon and directed by the Railway Committee, under heavy penalties for disobedience.

(*d*) Highway crossings.

I. A railway shall not be carried along a highway, but shall merely cross it, unless permission has been obtained from the Railway Committee, and, in crossing a highway, a good safe passage for vehicles must be kept open continually and no obstruction offered to travel.

II. In a level crossing, the surface of the rail must not be more than one inch above or below the general surface of the crossing.

III. When a highway passes under a railway, it must have at least 20 feet clear width and 12 feet clear height, and the gradient of the highway shall not exceed one in twenty, unless originally greater and left undisturbed.

IV. When a highway passes over a railway, the approaches shall not have a gradient of more than one in twenty, and must be fenced at least four feet high, and the bridges by which these highways are carried over the railway shall have a clear height of seven feet above the highest freight car hauled over the road, and over 14 feet clear width shall be given on approaches and bridges.

V. The company shall present to the Railway Committee (which notifies the municipality interested that they may oppose by a delegation) a plan and profile of every proposed highway crossing, and the committee will then decide whether it is to be changed in any way, or if a level crossing is approved of, whether a gate and watchmen are necessary to public safety, and the decision of the committee regarding details of construction, and also as to apportionment of costs between the company and other parties interested, is to be final, and followed out within a prescribed time under penalty.

VI. Sign-boards with letters six inches high shall be placed at every highway level crossing.

(*e*) Farm crossings.

One, at least, shall be made for every separate portion of land and for each disconnected portion thereof, so located as to be difficult of access otherwise than by means of a crossing of the railway.

(*f*) Bridges and tunnels.

Shall be built, maintained (and raised if necessary, whenever repaired or reconstructed), so as to maintain a clear height of seven feet between the top of the highest freight car used and lowest beam or obstruction of the bridge or tunnel.

N. B.—The Governor-in Council may except from this clause any railway on which air brakes are used exclusively. No company shall run cars over any bridge unless constructed and maintained with safeguards, and of strength approved of by the Minister.

(*g*) Fences and cattle-guards.

Whenever municipalities are surveyed or settlement exists, fences and cattle-guards shall be built and maintained, and in case of adjacent land being occupied, this must be done as fast as rails are laid, and the company shall provide gates having proper fastenings or hurdles at all farm crossings. When this is done, it is the duty of the landowner to keep the gates closed when not in use. If left open accidentally, no action for damages against the company can be sustained, and if left open purposely, a counter-claim for damage may be entered in addition to inability of recovering for loss of animals, etc., resulting from such leaving open of gates, etc. (Fences must be turned in to the cattle-guards).

(*h*) Opening of the railway for traffic.

No company shall open its road for passenger traffic until one month after giving notice in writing to the Minister, and after an inspecting engineer sent by the Government shall have reported favorably as to the safety of the road, strength of structures, and adequacy of rolling stock.

(*i*) Repairs.

Upon complaint of the officers of any municipality, the Government shall send an inspecting engineer to examine the condition of the road, and the company shall at once make such repairs as he considers necessary for public safety. Until such repairs are made the engineer may limit the number, speed or weight of trains and engines passing the point under repair.

(*j*) No discrimination in tolls between different persons or companies for the same service shall be allowed; any special rate allowed to one must be allowed to all.

(*k*) No secret special rebate or toll shall be allowed, and any company shall on demand make known to any one any special rate, toll or rebate.

(*l*) No discrimination between places shall be allowed, unless a lesser rate is necessary to secure freight at a competing point. (This, therefore, protects local points only against one another, and not against railway centres.)

(*m*) Every company shall afford full and equal advantages to all persons wishing to ship or travel over their railway, and shall afford equal facilities to each and every connecting line or lines of railway for transfer of traffic.

(*n*) Every company affording facilities to any express company shall grant the same to any other express company demanding it.

(*o*) Every agent of the company shall receive freight or any allowable traffic when offered for shipment, under penalty.

(*p*) Every train before crossing a draw or swing bridge shall stop at least one minute to ascertain from the bridge tender that the bridge is closed and safe to cross.

(*q*) At least 80 rods before crossing every highway (on level) a bell must be rung or whistle sounded, and this

must be continued at short intervals until the crossing is passed.

(*r*) An officer shall be stationed at every level crossing of two railways, and no train shall pass over it until a signal has been made to the conductor that the way is clear.

(*s*) Every train shall stop one minute at a level railway crossing as in No. 16, unless there is an interlocking system, when they may pass at such speed as the committee may allow.

(*t*) No train shall pass through thickly populated towns, etc., at more than six miles per hour, unless the track is fenced.

(*u*) No train or car shall be allowed to stand on a highway crossing more than five minutes at a time.

(*v*) All frogs, wing rails, guard rails, etc., shall be packed up to the underside of the rail wherever less than five inches space exists.

(*w*) Sections (*p*), (*r*) and (*s*) have been recently modified so as to permit of interlocking signals being introduced at junctions and railway crossings, in which case the Privy Council may permit trains to pass in or across at specified rates of speed without stopping, whenever the signals give the right to do so, but if the signals are not satisfactorily worked the council may revoke the permission.

For THE CANADIAN ENGINEER.

THE VENTILATION OF PLUMBING APPLIANCES.

BY W. M. WATSON.

In a former article I showed some of the evils attached to the present method of ventilating traps at the highest points, and the danger of venting plumbing in any case. I have never been able to find out the reason why such a complicated and expensive system was invented, but have an impression that the inventor erroneously thought that there would always be an upward current from the breather pipe at the ground line to the terminating end of the soil pipe above the roof, and there certainly would be if the temperature of the atmosphere at both points were always equal, or if it were always colder above the roof than it is at the mouth of the breather near the ground line. But sometimes it is warmer, and in that case there will be a down in place of an up draught. If the purification of the interior of the house soil pipes was aimed at, then the object is often frustrated by the choking of the street line sewer trap, or by the breather getting filled with stones, dirt, or weeds, and even when every point of the house drainage is free, open, and working well, we find that by adopting the Chicago and Toronto rules we are sacrificing the greatest sanitary privilege adopted, viz., the ventilating of the street sewers above the house tops, for the insignificant purpose of securing a very small and doubtful advantage.

When the soil pipe is connected without the street line trap, direct to the crown of the main sewer, as shown in THE CANADIAN ENGINEER of April, 1897, there is nearly always an upward current from the drain to the head of the S.P., because the temperature in the main sewer will generally be higher than the atmosphere, and if any exception to the rule occurred, causing a down draught, the foul odor in the house soil pipes would be forced into sewer, instead of out of the breather, which is the case at present. Since the American system of plumbing was adopted in Toronto I have noticed some of the places where fever and diphtheria have occurred, and I believe that statistics will bear me out when I say that the street line trap and vent-pipe method of plumbing is doing considerable damage. It is hard to choose between the evils of the careless putty and paint plumbing of twenty years ago and the intricate plumbing demanded at the present time in Toronto.

When Dr. Norman Allen was the medical officer of Toronto I asked him if he considered it right to spoil the ventilation of the public sewers and injure private property by compelling each owner to put in a trap at the street line of the private drain? His answer was, "No," but he reminded me that the by-law was passed by the council, and again altered within a few months, and that if another change was made so soon it would put both his department and the council at a disadvantage, because the public would get alarmed and lose confidence. The fact that the present officers who apply the law in Toronto are in no hurry to give their own private property the benefit of the Toronto plumbing by-law, proves that we might place them also as unbelievers in the system.

It is necessary to keep polluted air moving, and the vent pipes will help to do this; but to get air to circulate naturally, it must have a continuous circuit, and if branches are inserted into the line, the draughts will be spoiled, exactly as with the draught of a stove, when the smoke pipe is inserted into a chimney flue where there is another stovepipe hole open. Taking this fact into consideration, it shows that as every house must have at least three vent pipes, and two of them are branched into one, or all three are branched into a receiver, which in turn is branched into the side of the soil pipe, it makes it impossible to secure a natural draught through any of the pipes, because no continuous circuit can be formed, and the conclusion must be that the only real value the vent pipes can be, is, that they do away with any pockets where air may lodge in the waste pipes, and will prevent any chance of syphoning of the traps.

There is evidently a strong feeling in certain quarters in favor of creating unnecessary business, increasing expenses, and securing a monopoly in favor of syndicates and wealthy tradesmen, to the exclusion of the small ones. When reading the by-laws of Toronto one cannot but see that the sanitary advantages are put in the shade by the points that call for high licenses, heavy bondsmen, useless piping, labor and joints. Great waste is obvious in many places. In one case we find a sink only intended to catch water from a garden tap placed in the cellar that has about 40 ft. of 1½ in. iron vent pipe running level under the ceiling joists until it is attached to the w.c. vent. Now the friction that will have to be overcome before any movement of air can take place in a 40 ft. length of so small a pipe laid horizontally, is more than enough to totally prevent any action, and of course such a pipe is perfectly useless. In some small cottages rented for about $4 per month, having a w.c. and soil pipe through the roof, and on the opposite side of the house a sink with about two feet of 1½ waste pipe and trap attached to a properly ventilated drain, as also a vent pipe taken from the knee of the trap and continued up to above the roof, with 3 in. iron soil-pipe, costing about $14 each house, which expenditure is of no value for sanitation purposes, and it injures the current of air in the drain, and assists to dry out the sink trap.

There are a number of large towns, with a dense population closely packed together, in Europe, whose sanitary rules are of such a nature, and so well applied, that with all the disadvantages of the majority of the people working in close, heated rooms, having the fumes from grease, soap, steam, etc., to inhale, the death rate is less

than either Toronto or Chicago. The mode of application of their sanitary rules is both simple and effective. Before property can have the privilege of water supply, the waterworks' rules must first be complied with; also before it can secure the advantage of a sewage outlet to the street sewer, the health and sanitary laws must be fully carried out, and if property is not supplied by these necessary requirements it cannot be inhabited. But no public body can interfere with the rights that have already been acquired, except by paying compensation, unless the property is or contains a public nuisance and is unfit for public habitation, and even in that case the courts of law are not often required, for if an owner declines to keep his sanitary and waterworks appliances in good order he will receive notice to have them corrected, and when the time given expires, and the request is not complied with, the public authorities send their own tradesmen to do the necessary repairs, and charge the cost in the tax bills. This can all be done without threatening letters or a dozen visits from inspectors, and at a cost of about one-tenth of what it cost Toronto, and also without dragging the respectable citizens and tradesmen into a criminal court, or scaring weak people with official letters. When engineers and inspectors are clothed with absolute authority, those tradesmen who are compelled to work under them might almost as well hand their business over to the fortunate official, or make special efforts to please him in some other way, for there can be a wide difference between an inspector being satisfied with the work done at two different places, and by two different firms. I have had a letter in my possession from a former engineer of Toronto, in answer to a plumber's complaint about an official who had been unreasonable, and demanded more than the law required, which stated that the inspector could not be wrong, and he must be obeyed or a summons would be issued. The complainant then applied to the mayor, and the council appointed a committee which never met or gave the plumber a hearing. This sort of management usually occurs where business is done in favor of or by the requests of syndicates and monopolists that have a strong financial backing.

All rules and regulations made for the government of the general public should be plain, clearly described, easy to understand and carry out in every detail, definite and pointed, and having illustrated diagrams and plans showing what is wanted. It is unfair and unjust to allow any single person or body of officials to have the power to harass a tradesman, so that his expenses are increased and business damaged, while another friendly business firm may evade the law, or its work be easily declared satisfactory, securing good profits. The best sanitary laws are so framed that the most ignorant mechanic cannot make an error or mistake that will in any way injure the public health, and every detail of the fitting inside the building can be observed at a glance.

For THE CANADIAN ENGINEER.

FOUNDATIONS.

BY CHARLES BAILLAIRGE.

Allow me through the medium of your journal to call the attention of Canadian architects to the very concise and lucid illustrated article on "Foundations," which appeared in your last issue. The writer says: "The foundation of a structure is much more important than any other feature of its design, as on its security depends that of the structure itself." Our Canadian architects, I am loath to say, have not of late years been up to the mark in respect to foundations. Hence so many failures of buildings, especially of country or parish churches in the Province of Quebec, and other places which I might name, where the foundation areas, not being proportioned to the weight to be supported, portions of the structure have settled down unequally, tearing themselves away from others in a disgraceful manner, or to the disgrace of all concerned. I noticed this at J——— some three or four years ago, where the whole front of the church had parted from the side or wing wall, and the salient tower from the remainder of the front, due to its still greater weight, it having sunk eleven inches below datum level, and entailed an expense of some $7,000 or more in reconstruction. Other churches, I am told, as at the St. C. and St. B., have had to be, due to distortion by unequal settlement, taken down and rebuilt in toto.

Now the question arises as to at whose door the fault of such failures is to be laid. I must unhesitatingly say that, generally speaking, the architect is or should be considered the responsible party, and I cannot in saying this be open to any suspicion of partiality towards contractors, being one once myself, having practised as such for over twenty years before entering on civic service, and am still doing so. The architect should in every case plan and specify his foundations in a way that, if so executed, they may be thoroughly reliable, and then in case of the parish, through assumed poverty or otherwise, refusing to put in such foundations, the architect should execute the work under protest, so as to clear himself thereafter and saddle the blame where it belongs. The contractor should act in a similar manner, refusing to build a building under protest both to the architect and to the proprietors or wardens, in case of an improperly and inadequately designed substructure.

If the contractor carry out a plan as specified, he cannot be blamed for any failure due to settlement, as he is not supposed to form the necessary technical knowledge to allow him to judge of insufficiency and the ability of the soil to do what is expected of it in the way of supporting the structure. But the architect is supposed to possess this knowledge, and if he does not he should acquire it, or he is no architect at all worthy of the name. It is deplorable now-a-days that the engineer has to be called in to help the architect through with his foundations, for of the two the architect is the one supposed to have the more difficult problems to deal with sometimes, as in providing against the strains and thrusts to which sidewalks, piers and pillars are subjected by arched roofs or ceilings and domes of masonry, while with the engineer all these strains are conjured into submissiveness by the homogeneity of a pinned together or riveted structure, every part of which is thus tied and bound in a way not to give. What would architects of old have done had they not known how to proportion their resistance to their thrusts? There were no engineers in those days as we have them now. To what engineer did Michael Angelo apply to tell him how stout to build his piers to stand the pressure of St. Peter's dome, to load the supporting soil with weights proportional to their breadth of base? To whom did Christopher Wren address himself to study out the stresses of St. Paul's?—to whom the respective architects of the Pantheon, the Pantheon of Paris? They would have been ashamed, humiliated, to have had to rely in such matters on anyone else's knowledge than their own. It must not be argued that it is not less infra. dig. for the engineer to call in the architect to ornament his structure, make it artistic and acceptable to the age, than for the architect to call in the engineer. No, the cases are entirely different. Art and

ornamentation are a branch of architecture, the other two of the three components being constructive and distributive. Then, since the architect must know construction, he should possess all the technical elements thereof, and be able to prepare his own strain sheets, precisely as the engineer does at the present time, the architectural features in the engineer's case being a mere adjunct, while in the architect's case they are an essential.

The written protests I refer to are, of course (and may be more or less disagreeable) unpalatable to some or all of the parties concerned. The architect and contractor both fear that they may thus estrange or rile the proprietors into calling some other architect or builder pliant enough to do the needful and run all risks. "ruat coelum," but the absolute necessity of such action on the part of both architect and contractor in case of foundations of doubtful efficiency, has been so often and disastrously illustrated by the many failures alluded to, and the cost of repairing and rebuilding, that it is to be hoped that proprietors themselves, parish or other authorities, will see the necessity and philosophy of such action on the part of the architects and builders, and it certainly is not fair to saddle the contractor with the cost of underpinning or rebuilding, when they, (the authorities) have from motives of economy decided on a cheap "platform" or "grillage" foundation, where a piled or down to rack structure should have been decided on from the beginning. And in buildings in general, too much reliance is placed on the supporting powers of the outer walls. It is too easily forgotten, and more frequently ignored, that while each of the outer walls bears only one-quarter of the weight, the central wall will have double duty to perform, and hence the fact that so many structures sag at the centre. Another thing of vital importance in the rigidity of a building, and the supporting power of its floor, is that as far as possible every joint should have three points of support, or that they be made to extend from end to end of the building, while supported at the centre, or where there are two intermediate walls, that each alternate joint be made to reach and to bear upon the wall or the opposite sides of the corridors. Where this is not done the floors sag disgracefully towards the centre, and the mere walking across them causes everything in the room to shake and tremble most disagreeably, as with a certain building erected in Quebec, where not from negligence or any consideration of economy, but from sheer ignorance on the part of the architect of the difference between the strength of a beam when secured at the ends and extending to other points of support, as compared with one bearing loosely at its extremities on the supporting beams. Look at the late London, Ont., disaster. Had the joint in this case been of a single stretch from wall to wall, their combined strength, even without the beam which broke, would have gone far towards supporting the weight of the crowd in the room where the collapse occurred, and at any rate their resisting powers added to those of the incriminated beam would have prevented the accident; but on the contrary, every one of the joints were in two length width, their ends meeting on the centre beam, hence the failure.

For THE CANADIAN ENGINEER.

ROAD MATERIALS AND CONSTRUCTION.

BY W. M. WATSON.

When making roads we have the privilege of copying the system of construction used by the makers of the old Roman roads, which are yet sound and firm, and the later methods used by Metcalf, Tilford and Macadam, who revived the Roman and Swedish process of road-making in a lighter and less expensive form. This country is rich with first-class materials, which only require to be intelligently put together to make good roads. Each old road-making sample shows us that every road and street must have its roadbed well drained. When making a new road the sod and small under brushwood should remain, if convenient, intact, because the rootlets make a tough foundation to build the stone bed on. In places where artificial banks have to be made to raise the level of the road, or when crossing bogs, marshes and soft places, a good thickness of pea straw or brushwood, etc., should be laid across on the soft material before commencing to build the stone foundation.

When the Romans set out a new road, they cut a trench along each side line at least one foot deeper than the bottom of the intended roadbed. These were filled with large boulders, or a rough drain was made, with outlets at short distances into some natural water course, which efficiently drew off all the water from the under side of the foundations. Macadam rounded his roads a little on the surface, the crown being at the centre, giving them a gentle fall to each side. He constructed his roads by laying down three, four, or more layers of stone about six inches thick, rolling each layer down even on the surface to the same shape and grade that the road would finish. He suited his material used to the nature of the ground and the traffic that would afterwards use the road, always placing the largest lumps at the bottom, and rubble varying from one inch down to one-quarter inch for the top course, having the whole rolled hard and tight together, but using no sand or soft material except water. Hard frost cannot hurt a road that has a dry foundation.

Short residential streets might be made to fall a little to a central channel only about one inch deeper than the road surface, placed vertically over the main street sewer, having iron storm water grids that would serve both the purpose of ventilating the sewer and drawing the water from the street. This methed does away with the nuisance of having costly trapped gullies, with large pockets filled with decayed matter, throwing off disagreeable odors, close to the sidewalks and the houses. It saves digging across the street to the gullies, besides the value of the branch lines of pipes from the centre sewer to the gullies. It allows the wagons to get close to the sidewalks, and gives a width of dry road during a rain storm and frosts near to the houses where it is most needed. It also prevents the traffic from passing over the main drain where the road is weakest. Then the roadbed and foundation falling to the centre can be easily made to drain itself into the main pipe sewer, and last, but not least, the side of the streets will not be so slippery as under the present system in frosty weather. This method of grading streets is by far the cheapest, and the pavement is more durable and healthier for our climate.

We now come to roads suitable for traffic in populous cities, requiring smooth surfaces, and we revive again the customs and road materials used by the old Babylonians, and of Egyptians. There are numerous kinds of materials manufactured for roads and sidewalks that will stand any kind of weather, and that may be got at a reasonable cost, wearing from 20 to 50 years, and always be neat in appearance and comfortable to the wearer during the whole of the material's lifetime.

For instance, where high temperature destructors are used to destroy the garbage, the residuum is a very hard burnt clinker and fine ash. C. & A. Musks, of Bootle, Eng., have invented a press and other machinery to manufacture the clinkers into concrete flags equal to stone, and

less liable to retain moisture, and I here give a report published of the manufactory at Liverpool, of slabs made from one-third cement and two-thirds clinker, and ash taken from the garbage destroyer.

COST OF MANUFACTURE OF ONE YARD OF CLINKER CONCRETE FLAGGING, 2½ INCHES THICK.

Materials.	Cost.	Remarks.
65 lbs. of Portland cement	10¾d.	Varies with cost of cement.
152 " of clinker.....	nil.	Really a saving of 1¾d.
Water	¼d.	This item could be dispensed with where pressure is obtained by using steam power of destructor.
Labor	5½d.	
Plant contingencies and supervision	3¼d.	
Total cost per yard	1s. 7¾d.	

The total cost of manufacture is thus about 1s. 7¾d per square yard, without reckoning the saving in using the clinkers. The sizes of the slabs that are made are 2 feet by 2 feet, 2½ feet by 2 feet, and 3 feet by 2 feet,. each being 2½ inches in thickness.

Some of these slabs have been laid twelve months and show no sign of wear. From the experience already gained, engineers believe that this class of flag will have a life as long, if not longer than stone, and owing to the porous material with which they are made, the clinker paving slabs have a foothold much better than the natural stone.

TESTS MADE AT LIVERPOOL OF MACHINE-MADE CLINKER CONCRETE FLAGS 2½ INCHES IN THICKNESS.

Age of flag.	Breaking load applied at centre of flag.	Age of flag.	Breaking load applied at centre of flag.
4 months	1,804 lbs.	6 months	2,061 lbs.
4 "	1,474 "	6 "	1,966 "
4 "	1,742 "	4 "	1,859 "
4 "	1,917 "	4 "	1,659 "
4 "	1,608 "	4 "	1,589 "
4 "	1,752 "		

Concrete sidewalks made from granite chips and cement are pleasant and safe to walk on for about eight months in the year, the balance they are very slippery and dangerous. Wood sidewalks are slippery in wet weather, unsanitary, and at all times unsuitable. So that something in the shape of slabs that can be taken up and again replaced, and that are not slippery, also having a smooth surface, seems to be in demand. In places where they use a suitable wood set on a well drained thick concrete foundation, for street pavements, its wearing power is almost equal to good stone, having the advantage of being noiseless and easy for horses' feet. The wood most in favor at the present time in Europe is Australian hard wood, the best being called karri and jarrah. See table of strength, etc., below, prepared by James P. Norrington, C.E., London, England:—

	Local Name.	Weight per cubic foot in lb.	Breaking stress in lb. per square inch.	Elasticity in lb. per square yard.
West Australia.	Karri	65·00	215·00	7,070·000
	Jarrah	56·00	171·00	2,940 000
New South Wales.	Ironbark	73·85	25·08	5.526 400
	Blackbutt	65·69	21·70	3,105 979
	Mahogany	75·06	19·75	3,741 376
	Tallow wood	72·06	16 16	2,274 790

Colonel Bell, United States Consul, at Sydney, strongly recommends his own countrymen to use the Australian hardwood for paving in place of their own lumber. A test made of wood pavements at Euston Road, London, Eng., by James P. Norrington, C.E., proved that at the end of three years, the wear of jarrah and karri was only ¼-inch, and with yellow deal, it was worn down 1⅜-inches. I suppose our Canadian light cedar blocks would have gone out of sight altogether. The same engineer gives the cost of pavement complete with one foot thick concrete foundation to be $3 per square yard.

For sidewalks, cement and brick are good wearing when properly made, having a dry foundation of broken clinkers or coarse gravel. Tar pavements are smooth, durable and noiseless when made with well seasoned material. The tar should be stored in a cistern for over six months before using, so that the volatile oils and moisture come to the top, and are removed, then mix the tar with clean, small broken stone, say from one to three eighths in size, heated to a high temperature, so that the stone will absorb the tar without ignition. The longer the material is mixed before being used, the better road it will make, say within two years. This kind of road can be freshened and repaired with boiling tar and sharp sand when defects occur.

The best and most durable roads are made of pure genuine asphalt scientifically mixed with suitable materials; but, unfortunately, this is seldom except on sample patches, and the adulterated article cracks, gives out, and rots away under vibrating traffic. Asphalt is found in several countries, the best quality and largest supply is at present at Trinidad.

Asphalt is black and brittle at an ordinary temperature; when broken, the fracture takes the shape of a shell; when two pieces are rubbed together, an agreeable odor is emitted, having no resemblance whatever to coal tar. Crude asphalt weighs 65 lbs. per cubic foot, and refuses to attract moisture. It becomes partially soluble in turpentine, ether, petroleum or naphtha. Almost from the creation of man, what is now called asphalt seems to have been known and used. Its use and value is now being increased. Asphalt pavement is a composition with pure refined asphalt as the basis, mixed with 68 parts of sharp sand, 15 of powdered limestone, and 17 of asphalt, all the portions heated to a high temperature, and mixed by machinery while hot, and afterwards stored in a dry place or carted in a covered wagon to the place needed, and laid down warm. When laid on a firm and strong concrete foundation, the road will wear well, and stand heavy traffic.

For THE CANADIAN ENGINEER.

FRICTION.

BY WILLIAM PERRY.

Friction is greatly influenced by the hardness or softness, smoothness or roughness of the surfaces rubbing against each other. It is in proportion to the pressure or load, that is, a double pressure will produce a double amount of friction, and so of any other proportionate increase of the load. The friction does not depend upon the extent of surface, the weight of the body remaining the same. The friction is greater after the bodies have been allowed to remain at rest for some time in contact with each other, than when they are first so placed; as, for example, a wheel turning upon gudgeons will require a greater weight to start it after remaining some hours at rest than it would at first. The cause of this appears to be that the minute asperities, which exist even upon the smoothest bodies, gradually sink into the opposite spaces, and thus hold upon each other; it is for the same reason that a greater force is required to set a body in motion than to keep it in motion. If about one-third the amount of a weight be required to move that weight along in the first instance, one fourth will suffice to keep it in motion. The friction of axles does not at all depend upon their velocity; thus, a railroad car traveling at the rate of 20

miles an hour, will not have been retarded by friction more than another which travels only 10 miles in that time; it appears, therefore, that the amount of friction is as the pressure directly without regard to surface, time or velocity. Friction is greatly diminished by unguent, and this diminution is as the nature of the unguents, without reference to the substance moving over them. The kind of unguent which ought to be employed, depends principally upon the load; it ought to suffice, just to prevent the bodies from coming into contact with each other. The lighter the weight, therefore, the finer and more fluid the unguent should be.

As regards friction in water pipe, it does not matter whether the water is flowing down or up hill, or whether the pressure is light or heavy, or in long conical and smooth pipes, or whether it is flowing to or from the small end. The total friction will be the same in one or both directions in the first case, and the same in both directions in the last case. In the conical pipe, however, the friction per unit of length or per lineal foot will be less than the average at the large end of the cone, and more than the average at the small end. The total frictional head will be the same as though the whole pipe had a uniform diameter, just equal to the diameter in the conical pipe at the point where the friction is equal to the average for the whole length. I wish it to be understood that when I speak of friction in water pipe, I mean literally what I say —resistance encountered within the pipe by the water, friction in water pipe, not of water pipe. The velocity and resistance vary in different size pipe. If in a section of water pipe we take two points 100 feet apart, and find that with a given number of gallons flowing per minute, the actual pressure in the first instance is 100 pounds, and in the latter 99, we figure that the sum of the resistance in that length of pipe is one pound, or the loss by friction is one pound. If we go another 100 feet we get but 98 pounds, or the friction loss will be two pounds, and the ratio of loss will extend for miles in length. If the number of gallons flowing in the pipe is doubled, still keeping the pressure at 100 pounds at the first point, we shall get about 96 pounds at the second and about 92 at the third point, and we find by doubling the velocity of the flow, we increased the friction loss four times. It is surprising to note the great increase of loss from friction in small over large pipe, discharging equal quantities of water.

Discharging Pipe.	Gallons per minute.	Velocity in feet per second.	Friction in pounds
2½ inches	300	19.6	23.06
3 "	300	13.6	11.2
4 "	300	7.66	2.66
6 "	300	3.40	0.37
6 "	1,000	11.3	3 88
8 "	1,000	6.38	0.94
12 "	2,250	6.38	0.63

In the face of all such facts, towns and villages will use small pipe. I could mention quite a number of towns to-day with a water supply only fit for household service, and crippled in case of fire.

The internal surface of fire hose in a number of cases adds to the loss of pressure by friction to a much greater degree than is generally supposed. The writer's interest in this matter has grown from a desire to obtain better and more reliable information on these very important points. Installing quite a number of fire protection plants in the Dominion has enabled me to go very fully into the matter of friction in hose and pipe; in canvas hose there is a loss of from 25 to 50 per cent., rubber hose from 10 to 30 per cent. Yet from time to time you will see some new-fangled coupling introduced. I came across one some time ago arranged as a cone; the idea of the inventor was no doubt to prevent blowing out from the hose. It was 2⅛ x 2⅜ in. inside, and intended for fire department 2½ hose. With a test on ordinary rubber hose there was a friction loss of 38 pounds, and with the ordinary 2½ coupling under the same pressure 18 pounds on the same hose. Quite a number of such are on the market. All contractions in couplings, projecting washers, automatic cut-off valves, are very detrimental to the efficiency of flow of water, and are first-class friction producers.

CANADIAN NICKEL.

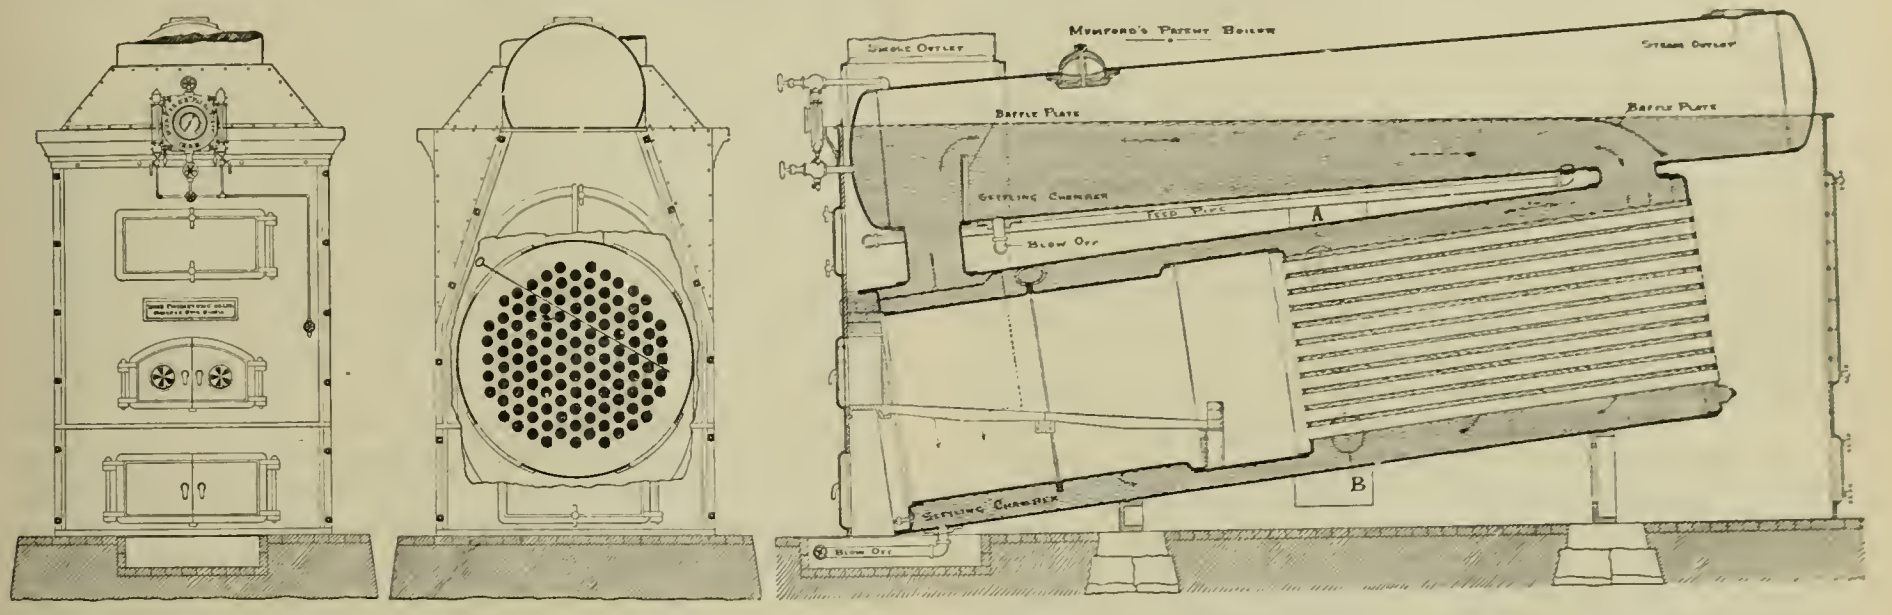
There is nickel ore in Ontario and New Caledonia, a French possession in the Southern Pacific, which can be profitably placed on the market. The market is world wide, for nickel has been decreed by the leading metallurgists to be necessary to the naval construction of the future, and the demand for warships is limited only by the credit of the nations or the endurance of their taxpayers. The copper bearing Ontario nickel ore is the more profitable, and its competition, although the development has been slight as yet, is said to have almost ruined the French company. Would not these facts lead us to expect to find a great industry in Ontario mining, smelting and refining nickel? Instead of that we have the Canadian Copper Co., whose mines, its manager, R. M. Thompson, stated before a committee of the United States Congress, "are owned entirely by Americans, and in treating whose ores they use American coke." He also stated that the $28,000 per month which the company was obliged to spend in Canada is made up for by the expenditure of $100,000 per month in the United States.* "The Canadian Copper Company is a United States corporation chartered by the Ohio Legislature, in which is only one little stockholder in Canada, holding perhaps one hundred or two hundred shares of the company," stated the president, Stevenson Burke, before the same Congressional Committee. The question now before the Dominion Parliament is whether Canada should not in her own interests place an export duty upon the ore and also upon the nickel matte, which is the product of the smelting process, heavy enough to render it necessary for the company to erect refineries in Canada and give Canadian labor the benefit of the working of Canadian ore. The boards of trade in various leading cities and towns have endorsed this proposal. The sentiment of the public generally seems to be that Canada should have reasonable use and profit of her resources, and that export duties seem the most feasible way of securing it.

It was rather a curious circumstance that at the meeting of the Federated Canadian Mining Institute held in Montreal some little time ago, so determined an effort was made by some of the members to secure an expression of opinion which might be used in the service of this alien corporation. It is certain surely that no stockholder of the company was present because it was a meeting of Canadians, and we have the president's statement that the members of the Canadian Copper Co. are all citizens of the United States, with one exception, and it is hardly likely that out of Canada's millions of people, that one man was present. We are credibly informed that the Canadian Copper Co. paid a ten per cent. dividend last year and carried a comfortable sum to the rest account. We hope the Canadian nickel company may soon do the same.

*See Sixth Report Ontario Bureau of Mines.

MUMFORD'S IMPROVED BOILER.

On this page we illustrate a new boiler intended to meet the demand for greater economy and efficiency than are obtained from the ordinary brickset boiler. The water circulation is similar to that of a water tube boiler, and for very high pressure it is built with a corrugated furnace. It was designed by J. A. Mumford, and is manufactured in Canada by the Robb Engineering Co., of Amherst, N.S., and in the United States by a large concern in Erie, Pa. The furnace has ample room for mixing the gases, and is surrounded by water so that the direct and radiant heat of the fire is readily absorbed. The heated gases pass directly through well-proportioned tubes, and return around the shell of the boiler and underneath the drum; thus, it is claimed, making every square foot of the boiler effective as heating surface, and enter the smoke stack with sufficient temperature remaining to produce good natural draft. By covering the case and drum with a non-conducting material the loss of heat is reduced to a minimum. The water circulates continuously from the front to the back of the boiler, up the back connection to the drum, where the steam freely separates from the water, and down the front connection to a point below the fire. This positive circulation admits of using forced draught, increasing the horse-power of the boiler without foaming or priming, the increased temperature increasing the speed of the water circulation, the makers claim, without any evil effects.



Special arrangements are made to avoid trouble with bad water. The feed pipe enters the drum near the back end, and part of the sediment is deposited in a settling chamber at the front end of drum and may be blown out. Additional impurities that are carried down the front connection are deposited in another settling chamber below the furnace. This leaves very little, if any, impurity to form scale on the furnace and tubes, and it may be removed by a scraper inserted through hand holes in the shell, the tubes being spaced so that all can be cleaned. Doors are placed in the casing opposite these hand holes which also give facilities for cleaning the outside of the shell. The Robb Engineering Co. inform us that they have already installed two of these boilers in Montreal, and others in Lethbridge, N.W.T., Fort William, Ont. and Parrsboro, N.S., while a number more are ordered.

THE NAVIGATION OF THE AIR.

Editor CANADIAN ENGINEER:

In your issue for November I notice an article on "The Navigation of the Air," by C. Baillairge, C.E., and thinking some of your less scientific readers might be left in the dark through the nature of his article, I am led to make a few remarks, in the hope that they may somewhat clear the obsurity as to the principle, method and nature of the most successful attempt at aerial navigation in the last few years.

In the article Mr. Baillairge says, "that there never has been an attempt (at imitation), as with flying machines, to imitate in the balloon the shape of a bird on the wing;" and then again he says, "there must be (imitation), to be successful in directing them" (balloons). Now here we have a man trying to advocate an old and exploded theory, that of navigating the air with a machine that is itself many times lighter than the element in which it floats. Not on, remember, as in the case of the ship, which case he tries to parallel with that of the balloon, and says, "as man has become (successful) in propelling vessels through the water, by building them in imitation of the fish." Here we see what similarity exists between a fish and a modern steamship, such as the "Lucania," as ships, I believe, move partly through and partly over the water, whereas the fish moves entirely beneath and through that element. Now as to the propelling power, with reference to that of the fish, again we fail to see the similarity between the two. The fish propels itself by its tail, using its fins as auxiliary motors; but in the steamship, where is the mechanism representing the tail or the fins of the fish? It is true you will find the respective motors in the same relative position, but the resemblance between them I think is very slight. One being an oscillating movement of a fan-shaped appendix, the other a rotary motion of a blade screw. So that we see that the supposed likeness, referred to by Mr. Baillairge, does not really exist.

Then he continues: "Nor will flying-machines ever prove a success until some closer imitation has been arrived at, than heretofore, of the winged denizens of the air." Now, to take some other problems that have been solved by our inventors and mechanical engineers, not in the way suggested, by adhering strictly to Nature's models, but by radical departure in some instances. Firstly, had we imitated the ox or the horse and made the machine which draws our trains to-day, walk on legs, instead of roll on wheels, we undoubtedly would not have had trains whisking us through space at 60 and 112½ miles per hour. Secondly, had our marine architects imitated the fish and his oscillating tail we would not have had a "Campania" or "Lucania" crossing the Atlantic in less than six days, or a torpedo boat rushing through the water at 37¾ miles an hour.

Then is not a flying machine proper, the "aerodrome," a nearer imitation to nature's model than the "soaring machine," advocated by Mr. Baillairge, which is merely what is known as a "steerable balloon," slightly modified? I think so, inasmuch as it is vastly heavier than the air, which fact is true of nature's various models. Then again, he continues, with reference to the relative buoyancy of the balloon against that of the air-ship, "thus, as it is, the balloon is buoyant, but without the proper shape to render it possible to direct its motion, while the 'sky-flyer'—this we interpret to mean air ship, though we never have heard the term used before—is deficient in the opposite sense of having the power of direction without the buoyancy." We doubt if the latter part of the above statement will stand investigation, for surely had the author made the slightest pretence at ærodynamics or æronautics he would have known that the flat or concave surface of any considerable extent (not being prohibitively heavy) when held rigidly at an angle of from 3° to 8°, and moved rapidly forward in a horizontal line, does not need any buoyance outside of itself to retain it in space, its own onward movement being sufficient. That this is the true principle of air navigation has been proved by Langly, Maxim and others. And we may say here without going further, that our inability to steer balloons is not on account of their shape but on account of their weight, or more correctly speaking, the absence of the above property. Had a balloon got the weight, still retaining its floating qualities, there would be little difficulty found in directing its motion.

A little further on Mr. B. tells us to "try to conciliate or combine the two requirements or desiderata."—that of the balloon and air-ship—the two he says must be blended. Believing him to be an advocate of the rule, that "nature must know best," and that in experiments nature's models should be followed as closely as possible, his argument here seems not a little inconsistent. Here we would ask him, if instituting a compartment filled with gas in his flying machine or bird-like structure is imitating nature's model? and if so, in what part of the bird's anatomy the balloon-like structure is located? Further on continues the author, "there is another cause which helps the bird to soar on air" (the first cause mentioned was the bird spreading its wings and extending its tail so as to underlap them, thus forming a kind of æroplane) "this is the very heat generated by the bird's body." Then he asserts that the heat generated by the bird rarifies the air contained in the cavity between the wings. Now, to the generality of us this statement is rather confusing, for heretofore, we were not aware that any cavity existed between the wings, though there may be something of that nature beneath them, it is generally believed that between the wings is located the birds body. As for the air being rarified by the heat of the bird's body and imparted to the cavity or concaved surface of the underside of the wing, thus having

a tendency to lift still further or at least retain in space, we think this factor too insignificant to be reckoned with, as figuring out on a scientific basis will prove. In the next paragraph, the writer asserts that "the soaring of the birds of prey is due to their flesh-eating propensities, which creates in the blood a vast amount of carbon, and when brought in contact with the oxygen of the air, in rapid respiration, sets fire to the interior. Now here we have the bird of prey making a veritable furnace out of its stomach by its own action, and the heat generated thereby being used balloon-like, to help maintain its position in space. Then he says with reference to the soaring faculty of the bird, no other explanation can be offered save the one he adduces. Surely this is a sweeping assertion. He then makes reference further on to the "ball-cock" or nozzle mystery, of which he says he gave the first explanation; here again we think he is not quite correct, but he does not give data to his explanation. He states that "increased buoyancy might be obtained under a flying-machine or parachute." Here in particular, as all through his article, he seems to be mixing matters by using such terms as "balloon," "flying-machine," "air-ship," "sky-flyer," "ærostat," "imitative bird," "æroplane," and parachute," some we think peculiar to himself, but most of them universal terms used to designate a particular style of machine for navigating the air, but in this article they all seem to relate to his peculiar machine, whatever he intends to name it, and to the mind of the average reader renders his article rather obscure. Surely it must be a singular looking object that could be called literally a flying-machine or parachute. Then going further with the matter of buoyancy it is asserted that by causing a jet of steam, or a jet of gas or atmospheric air to issue from ball-nozzles or concentric cones, so as to come in contact with the concaved roof of the flyer, and by the mere effect of the friction, suck the air from the funnel-like space enclosed by the jet, thereby forming a vacuum within, and in this way producing buoyancy sufficient to float the flyer, the overplus power of the buoying contrivance to be applied in propelling the "bird-like structure" through the air. Here I would ask the author if he has ever got down to facts and calculated the power and weight of engines or motors of other kinds necessary to compress air or produce steam sufficient to supply ball-nozzle or concentric cone of the number necessary to lift a given weight say of 500 lbs., less the weight of engines (which is not a prohibitive weight, I think, for a practical "sky-flyer") or the area of ceiling or roof for the cones or nozzles to play upon, We think not, or he would have seen that the idea was too absurd to even dwell upon for a moment. But as the writer penned the foregoing statements he seems to have been reflecting, for in the next paragraph he says: "But better still, let the buoyancy be provided for in advance of starting by making the structure a balloon or space-enclosing one." Then he proposes to steer his balloon or soaring machine—for such it really is—by making the propeller shafts capable of separate action, and alternately increasing or decreasing one or the other's speed, in order to keep the balloon on her true horizontal course. How he is going to alter his balloon's vertical course or altitude he does not state, but we presume that this must be brought about by the escape of gas or ballast. With the method of steering suggested above it strikes us that quite a complement of engineers would be required, some one of them at all times would have to be perpetually working throttle, reversing lever, governors or electric switchboard, etc., etc. Here again the writer seems to have reflected on his preconceived method of steering, for in the next sentence he says, "and if the aerostat were provided with a rudder." Again as in other places throughout the article his second thought is infinitely better than the first. At the next bound the reader and his thought of air-ships is landed head over ears among astronomy and astromers, which having nothing in common with æronautics we will pass over without further comment.

And now to conclude with the suggestion to the writer, that if he has such implicit faith and confidence, and believes the principle of his machine to be the only and ideal air-ship of the future, the best method of proving whether his ideas are correct or not would be to have one built on a practical scale and make or attempt to make a flight with it. The danger of such a course is made all too apparent by the history of Dr. Woelfert and his balloon, "Duetschland," which caused the death of the doctor and his assistant, Herr Knobe, on the 12th of May last, at Berlin. This balloon embodied many of the features of the "sky-flyer." For practical matters on æronautic and ærodynamics, I would refer Mr. Baillairge to articles by H. S Maxim, S. P. Langely, Lilienthal and M. Tatin, also Æronautical Annual, 1896-7.

Winnipeg, Man.

The Waterloo and Hespeler Electric Railway wants $40,000 from Berlin and Waterloo, Ont., to extend their line to these towns.

For THE CANADIAN ENGINEER.

THE SWEDISH IRON AND STEEL INDUSTRY AS SHOWN AT THE STOCKHOLM EXPOSITION.*

BY ERNST A. SJOSTEDT, M.E., MONTREAL

Sweden has for centuries been so well known as a mining and iron producing country that it was expected to have something very interesting in this line to show the world at the Stockholm Exhibition last summer. But even to the most expectant and partial a genuine treat was here in store. For in a most picturesque neighborhood of the beautiful Swedish capital we found the varied products of the country brought together—not in a more or less haphazard manner, but of the choicest only, and this most tastefully and systematically arranged and displayed. The iron industry especially showed a remarkable life and activity; and the more we studied the different exhibits the more we must marvel at the truly wonderful material shown, the like of which has not been produced elsewhere in the world. In fact, such toughness and strength combined with such remarkable softness and pliability as the best grades of the Swedish iron possesses cannot even be approached by other nations, and its tool steel armor plates and projectiles stand highest in the world's market. Compared with any of the great iron-producing countries, Sweden occupies but an insignificant place, for while Great Britain and United States each produced about 8,600,000 tons of pig iron in 1896, and Germany 6,400,000 tons, Sweden can boast of only 545,000 net tons. But what here lacks in quantity is amply made up for in quality, as we soon will see.

In what a healthy condition the Swedish iron mines are, and of what superior purity the ores used at the Swedish furnaces, can be gathered from the following data:—The total number of (net) tons of iron ore raised in 1896 was 2,245,980, as compared with 1,088,120 tons in 1891. The principal producing districts and representative mines are:

	Net tons.
(1) Grangesberg (Dalarne), with an output of	704,000
(2) Gellivara, Luossavaara and Kurunavaara.....	660,000
(3) Norberg (Westmanland), about	171,000
(4) Dannemora (Upland) "	60,000
(5) Striberg (Nerke) "	44,000
(6) Persberg (Vermland) "	30,000

Of these, the Grangesberg and Gellivara ores are rich in iron (57 to 68 and 60 to 68 per cent. respectively), but high in phosphorus (.05 to 1.25 and .08 to 84 per cent.), and for this reason cannot be used in the Swedish blast furnaces where quality is aimed at, but are exported, the former principally to Germany and Austria where they are used in the basic (Thomas and Gilchrist) processes, and the latter to England, Germany, Belgium and France. All the other representative ores are exceptionally low in phosphorus—from .001 to .03 per cent.—and also in sulphur—from .01 to .05 per cent.—except the Dannemora "pyrite ores" with about 1.25 per cent. sulphur; which, however, are so thoroughly roasted that they do not contain more than .02 to .05 per cent. sulphur when being ready to use in the blast furnace. Upon these two points, the very possibility of the present active condition of the Swedish iron trade rests. And the practice of the great corporations holding the purest ore mines never to sell or export any of their ores, but keeping them for consumption at such works only in which they are interested, gives them practically a monopoly of the best pig iron and steel billet trade, and enables them to obtain a price for their product, in and out of Sweden, that would make an American ironmaster feel quite envious, although he may not be disposed to take all the numerous small precautions used here, which, however, are indispensable for obtaining such results.

As most of the iron ores are magnetites (in 1896 87.4 per cent. of the whole production was magnetites, and 12 6 per cent. red hematites), and as the red ores often are so mixed with the magnetic ores that they also are attracted by the magnets, the simple miner's compass has of old been quite an important factor in the discovery and tracing of the Swedish iron ores. During the last 20 to 25 years, however, the more complicated, but also much more accurate and scientific instruments designed by Prof. Thalen† and Mr. Tiberg‡ have come in quite common use. Together with the mining maps, models of the mines are generally made of a series of horizontal and parallel glass plates, on which the sections are drawn in clearly defined colors, representing the different minerals and rocks encountered. These models are without doubt both neat and instructive, and the idea well worth imitating at every mine, as it shows at a glance all the shafts, levels and work-

*Abstract from a series of articles written for *The Iron Age* while at the Exposition.

† Thalen's Magnetometer, described by the writer in the Journal of the U.S. Association of Charcoal Workers, Vol. VIII., p. 262.

‡ Tiberg's Magnetic Inclination Balance, described by the writer in the Trans. of the Mining Association of Nova Scotia, Vol. II., p. 117.

ings, and thus gives a much surer and clearer idea of its condition than any number of sectional maps possibly can do.

The blast furnaces of Sweden—as well as in the Lancashire process of making wrought iron—are all using charcoal as fuel, and in most of the other metallurgical operations, such as the roasting of the ores, in the heating and open hearth furnaces, etc., the generator gases from wood, forest and mill refuse are used to a great extent. The coal mines of Sweden, namely, which occur only in the extreme south part, in Skane, and from which in 1896 nearly 250,000 net tons of coal were raised, are not of sufficient purity for the iron industry, but are mostly used in the manufacture of firebricks, as good fire clay is associated with the coal beds. Hence it is that sawdust and slabs from the mills, branches and stumps from the forest—in fact anything of a combustible nature—is carefully saved and used in the gas producer, where it is made into pure gaseous fuel, free from sulphur, and thus most admirably suited for the iron and steel processes. Besides the abundance of waterfalls furnishes power for this as well as most other industries, thus leaving for the smelting processes, the lumber and pulp industries, almost the exclusive use of the raw materials of the forest. And as of old the Swedish ironmasters also have been large forest owners, the interests of both these industries have been identical, and the future and continuous prosperity of both have been looked forward to by planting, as well as cutting, and by a systematic working of and most scrupulous saving of the forest products.

Of all the iron and steel exhibits at the Stockholm Exposition it can be said that this excelled in exceptionally good products, and showed an unusual taste and system in arrangement. Conspicuous was also the diversity of products from the same works, showing how few of them really confine themselves strictly to any one particular branch, and how many convert their own raw material—pig iron billets or ingots—either into a half-finished product or into even the smallest articles of trade, many also going into the manufacture of lumber, pulp and paper, etc. The reason of this is evidently to avoid being dependent on the price fluctuation of the raw material, and to enable them to throw the bulk of their working force on that branch, among the different ones pursued, which at the time promises the largest profit.

Owing to the great demand for Swedish bicycle tubes during the last few years quite a new important industry has of late sprung up—namely, the manufacture of tubes of all dimensions. Another healthy branch of the iron industry is evidently the open hearth—especially the basic—process, which is growing in great favor, and from which large castings, as well as small samples were shown at most of the exhibits that testify to the great excellence of the material.

In 1896 there were 140 blast furnaces in operation, producing 544,858 net tons of pig iron, as compared with 502,625 tons in 1890—thus showing but a slight increase, which again is principally due to the limitation of the blast furnace fuel (the charcoal). The average output per furnace and working day was 14.3 net tons in 1896, and 13.3 in 1890, and the largest furnaces (at Domnarfuet) having produced an average of 28.9 net tons, while, of course, some of the smaller furnaces make considerably below the average. The tendency of the Swedish iron industry is indicated from the following table, which gives the proportions of the different kinds of pig irons manufactured in 1892 and 1895:

	1892. Per cent.	1895. Per cent.
For Lancashire and puddling	62.12	52.70
" Bessemer and open hearth	30.53	43 46
" laundry purposes	2.05	1.69
" malleable castings	1.10	1.86
Sprigel	0.19	0.29
	100.00	100.00

For the further manufacture of the pig iron into wrought iron and steel there were, in 1895, 137 different works, and the number of furnaces and the quantity of each class of iron produced were as follows:—

	Net tons.	
306 Lancashire forges, producing	190,517	
35 Franch-Comte forges, producing 33 Walloon forges, producing 16 scrap forges, producing	15,484	
Puddling furnaces at only 4 works, produciug	1,975	
		207,976
30 Bessemer converters, producing	107,247	
(Of which 19,672 tons are basic steel.)		
33 open hearth furnaces, producing	109,383	
(Of which 22,060 tons are basic steel.)		
5 crucible steel furnaces, producing	659	
		217,289
6 blister steel furnaces, producing		720
Total net tons		425,985

In order to give an idea of the different kinds of manufacture, and the growth during the last few years the following table is of interest

1 metric ton = 1.102 net ton. = 0.984 gross ton.	1891 Total metric tons.	1891 Per cent. Lancashire puddling.	1891 Per cent. Bessemer and Martin.	1895 Total metric tons	1895 Per cent. Lancashire puddling.	1895 Per cent. Bessemer and Martin.
Blooms, billets, etc., for export	8,083	0 1	99 9	9,488	0.14	99 86
Iron and steel bars	146,786	67.8	32 2	168,270	61 32	38 68
Other shaped iron and steel not hereafter specified	8,324	8 0	92 0	12,171	1 29	98 71
Hoop iron, horse nails	78,092	59.3	40.7	78,168	55.63	44 37
Wire, in coils	25,764	40 4	59 6	26,038	32 38	67 62
Heavy plates	10,850	0.7	99 3	12,028	0.51	99 49
Rails	3,644	..	100.0	2,884	..	100.00
Fish plates and rail plates	384	45.3	54.7	387	40 31	59 69
Wheel tires	1,391	..	100.0	900	..	100.00
Axles	1,975	34 9	65.1	1,897	17 34	82.66
Anchors and other heavy forgings	1,009	59.2	40.8	695	28 63	71 37
	286,302	55 3	44.7	312 926	49 86	50 14

From this we see that the percentage of Bessemer and Siemens-Martin metal in the manufacture of domestic material was below that of Lancashire and puddled iron until a couple of years ago, when it exceeded it; and the increase in this direction is steadily growing. Another table, showing the relation between hammered and rolled billets and bars and the increasing preference for the rolled product, may also be of interest:

Year.	Hammered. Tons.	Hammered. Per cent.	Rolled. Tons.	Rolled. Per cent.
1892	46,693	34.1	90,306	65 9
1893	43,072	31.8	92,479	68.2
1894	39,738	29.5	94,896	70.5
1895	37,381	24.2	117,229	75.8

Among the several iron exhibits, those of the Sandviken, Domnarfuet, Bofors and Tinspong were the most conspicuous; and the mentioning of a few of their articles will only go to demonstrate the opinion already advanced in regard to the excellent qualities of the Swedish iron and steel, as well as the superior skill displayed in the manipulation.

As samples of special skill in cold rolling long iron bands, the Sandviken Steel Company exhibited an iron band eight inches wide and 2,293 feet long, weighing 1,155 pounds, which decorated the walls and the ceiling of their pavilion, and as a contrast to this "heavy weight" we noticed a "light weight" champion of 4,205 feet in length, and 2⅜ inches in width, but only 43 pounds in weight. The thickness of this cannot be measured in the ordinary manner, as it is only about 0.0012 inch; but a still thinner one, measuring 0 0008 inch was also among these unique exhibits. Another "record breaker" was a band saw 12 inches wide and 214 feet long, handsomely polished and hardened, and "ready for work;" so was also a hot rolled band 290 feet long, 8 inches wide and 5 32 inch thick, weighing 1,241 pounds and made in one heat. This is believed to be at the same time, the heaviest and longest band ever produced in a similar manner in any part of the world. Below this coil was placed a billet of the size from which this band was formed, measuring 11 feet by 7¾ by 4⅜ inches, which object lesson makes one realize with what skill and dexterity this great change of dimensions must have been accomplished—as the result of only one heat.

Domnarfuet Iron Works—the largest iron and steel works in Sweden, and the largest in the world based on charcoal as fuel—displayed some heavy chilled castings, *e.g.*, two 26-inch rolls, about 11 feet in length, and weighing 16,975 pounds each; also open hearth castings, among which two 31-inch rolls of 17,195 pounds weight, and a piston of over six feet in diameter and 3,858 pounds in weight; so also a multitude of samples which had been subjected to the most trying mechanical tests, under heavy drop hammer or by strong torsion and bending, to prove the excellent quality of the material, as none showed any sign of a break or flaw. The superiority of the Domnarfuet tool steel was proved by showing the work done by some of them (duly attested): One of the turning tools had cut and turned off 2,336 pounds of open hearth steel shavings, 566 pounds of cast-iron turnings and 50 pounds of shavings from a chilled cast-iron roll; while a 2-inch spiral drill had bored holes of together about 14 feet depth, making 130 pounds of chips. Among car wheels exhibited by the Sandviken Iron Co., one pair had served during 21 years, and traveled 458,296 miles, and a pair of locomotive tires which had been running 236,817 miles in ten years; also a car axle that, after having run 444,845 miles, was tested and had to be bent 39½ times at an angle of about 10 inches from the neutral axis before it broke.

At Bofors and Tinspong guns, armor plates and projectiles are made, of which the latter especially are renowned at home and abroad,

and their power of endurance was shown at a trial practice at Creusot, when the three Tinspong 5.9 inch composition projectiles passed unharmed through the 9.8 inch armor plates made by the French works for the Swedisb Government.

The good welding quality of the Swedish steel, as well as the skill of the blacksmith, was demonstrated in a most interesting manner by a piece of steel in the shape of a cube, the end sections of which showed nine small steel squares of different hardness. This effect had been obtained by a perfect welding together of nine square steel bars, with carbon ranging from 0.2 to 1.0 per cent., after which this composite bar had been cut in pieces and polished.

In order to show to what great expense the Swedish ironmaster is prepared to go in order to gain even the slightest advantage in quality of product, it is interesting to note that at some of the works using the purest ores obtainable, they are actually killing out the birch wood, and in its stead planting pine, solely on account of that shade of a difference in amount of phosphorus present in the hard wood, over and above that in the soft wood. But as the trade gives preferences to him who can show the absolute lowest percentage of phosphorus in the steel—if even a difference of .001 per cent.—the wis ironmaster will go even to such a sacrifice—cost what it may, as long as the importer is willing to pay for it—and this England, at least, is always prepared to do for *the very best* material.

Peculiar to the Swedish iron works are their large number of dwelling-houses owned by the companies; but, generally, furnished rent free to the workmen. Although both expensive to build and to maintain, at most of the works this rather patriarchal system is adhered to, instead of allowing the men to buy their own plot and house. Generally, these are neatly built cottages of brick or logs, and pleasantly situated in some park or the woods surrounding the works, and give the impression of prosperity and comfort.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports of interest to the metal trade from Great Britain during March and the three months ending March, 1897, 1898:—

	Month of March.		Three months ending March.	
	1897.	1898.	1897.	1898.
Hardware and cutlery	£4.955	£2,113	£12,018	£5,418
Pig iron	20	639	455	2.541
Bar, etc.	830	78	3,031	2,285
Railroad	3,295	....	3,847	6.922
Hoops, sheets, etc.	2,700	869	6,311	3,653
Galvanized sheets	2 615	1,916	5,841	4.549
Tin plates	23,141	7.034	61,542	25,549
Cast, wrought, etc., iron	2,252	2,162	7,004	6,133
Old (for re-manufacture)	96	323	572	403
Steel	5,302	5,295	10,235	15,935
Lead	791	1,121	2,070	2,703
Tin, unwrought	947	2,087	5,444	3 476
Alkali	2,606	2,617	4,522	5,516
Cement	750	81	1,843	1,988

MONTREAL ISLAND BELT LINE RAILWAY.

We described at some length in our last issue the Montreal Island Belt Line Railway. The following additional details of the equipment have kindly been supplied us by C. H. Wright, electrician, and R. Welsford, engineer of the company: The generatoi is the well-known Canadian General M.P. 200 belted dynamo, and runs at a nominal pressure of 550 volts. The switchboard is the standard marble generator panel, made by the same company, and furnished with its circuit breaker, switches, etc., while the indicating instruments are of the Weston switchboard pattern. The four closed cars are mounted on Taylor double trucks, and equipped with G E. 1,000 motors. The two 45-feet cars are mounted on Taylor double trucks, with G E. 1,200 motors. The five 30-feet cars are mounted on Brill single trucks, with G.E. 800 motors. The cars are made by the General Electric Company and the Ottawa Car Company. They are lighted with about 225 candle power of incandescent lamps. The line is 00 trolley, with a parallel feeder of 0000 bare wire from the power house, and tapped every 1,000 feet to the end of the line. Bracket construction is used, and the trolley wire is 22 feet from the ground; soldered ears and Crayhead brackets make the overhead work very durable. The bonding is 0000 solid wire, with malleable iron thimbles sweated on. Rails were drilled in the pile with upright hand drills. The cars are controlled by a non-inductive telephone system from the superintendent's office at the power house. The car sheds are located at the power house, so that all the operations of the line are controlled from this central point. The line is completely fenced with Page steel wire fence. The River Side power house of the Montreal Belt Line Railway is situated on the banks of the St. Lawrence, and in the middle of its line. The power house is built of pressed brick of the Ormstown manufacture. The size of the building is 44 feet by 84 feet. The engines and boilers are made by Goldie & McCulloch, Galt, Ont., and consist of one double tandem compound Automatic Cut-off engine, size 13 x 24 x 36 inches. The wheel, 16 feet 6 inches, is belted directly to generator. The boilers are made from the best homogeneous steel, and are double riveted with 84 tubes in each, and tested to 180 lbs. pressure. The condenser pumps and boiler feed pump are made by Northey of Toronto, whose wares are well known to manufacturers. Size of condensers are 6 x 12 inches, and 9 x 12 inches. Size of boiler duplex feed pump 6 inches, 4 inches x 7 niches. The horse power of the engines is 300.

JAMES KINOCH, CHIEF ENGINEER CANADIAN GENERAL ELECTRIC COMPANY.

Jas. Kinoch was born at Blair Gowrie, Perthshire, Scotland, in 1866. The greater part of the years spent in securing his education were passed in London, where he attended the City of London Middle Class School. His technical education was completed at the City and Guilds of London Institute, under the tuition of such able instructors as Profs. J. Perry and W. E. Ayton, and Sylvanus P. Thompson. He graduated from the Institute with great credit to himself.

After completing his technical studies Mr. Kinoch entered the employ of the Globe Electric Engineering Co., where he remained for three or four years. He then became secretary of the Orient Electric Light Co., which position he retained for nearly two years

JAMES KINOCH.

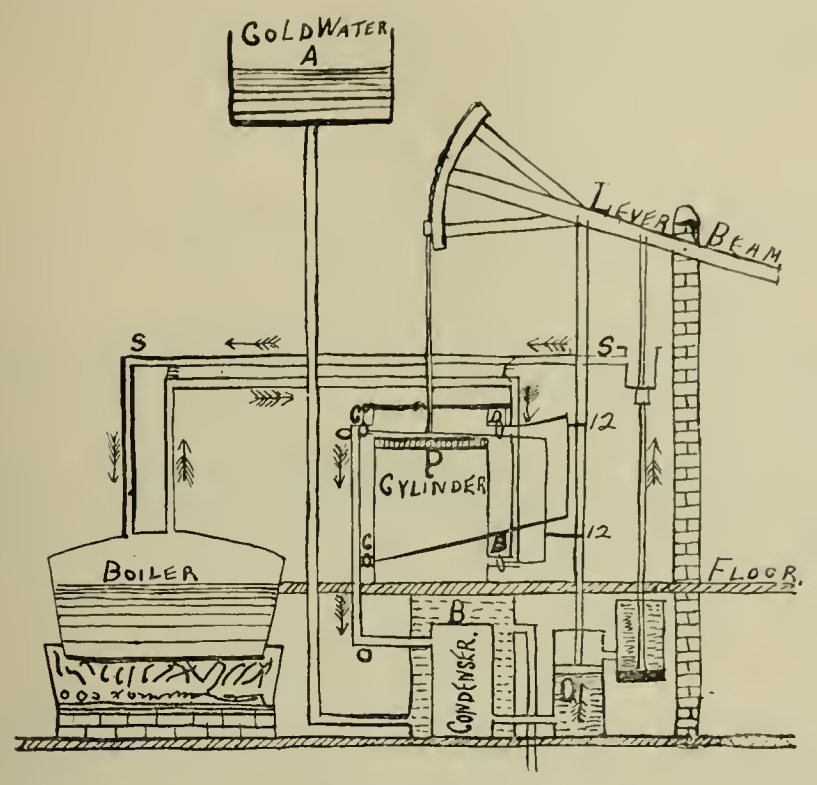
After two years' experience as chief assistant to Killingworth Hedges, Mr. Kinoch came to Canada in October, 1891, and entered the service of the Edison General Electric Co. in Toronto. When this company combined with the Thompson-Houston Electric Co., and the Canadian General Electric Co. was formed to carry on its business in the Dominion, Mr. Kinoch was employed as estimating clerk. He filled this position, except for a short time spent with the construction staff on the road, till he was appointed assistant to the chief engineer, and last month received the appointment of chief engineer to the Canadian General Electric Co.

THE STEAM ENGINE.

Editor THE CANADIAN ENGINEER.

SIR,—In a former paper to your readers I drew their attention to the horse-power or duty, and to Newcomen's atmospheric and steam engine which Watt repaired for the University of Glasgow. His attention was directed to improvements which he saw could be made, and he and Dr. Roebuck went to work to make a new one of a useful size for the Doctor's mine; in his house and in his Carron iron works he fitted rooms for the purpose; there we left him, getting his patterns and casting ready. They had undertaken a big job, as all their tools had to be planned and made. We will now follow him into his room, where he had his steam engine working. Herewith I present a sketch of the engine that was in his mind some time before. The condenser is below the steam cylinder, in a tank of cold water to help the spray or jet of water inside; also he had two pumps connected to the main beam to draw the water out of the tank, and also to fill the boiler feed tank. Here, you may observe, his engine worked with steam both sides of the piston. It was made to work any machinery, as well as pumps in a mine. This condenser formed a better vacuum than could be formed before, and his engine made about fifteen to twenty strokes per minute and ran much higher pressure steam, and by making the vacuum in the condenser as good as possible, so that he might gain 12

or 14 lbs. on the square inch; or, in other words, his pressure of steam on the piston may be that amount less in the boiler; his valve levers are connected to the main beam. The next gain he wanted to make was to keep the cylinder warm, it being exposed to the cold air, as well as the pipes to it from the boiler. He conceived the plan of having another cylinder fitted around it and cased with wood, and let in a little steam at the top, and the condensed water ran out at the bottom.



WATT'S ENGINE.

A, *B*, cold water tanks. *C*, outlet for cold water. *D*, *F*, pumps for drawing off hot water and sending it along *s s* back to the boiler. *P*, tight-fitting piston. *a*, *d*, cocks for letting steam into the cylinder. *b*, *c*, cocks for letting steam out of the cylinder. *e*, *e*, pipe which carries steam from boiler to cylinder. *o*, *o*, pipe which carries steam from cylinder to condenser. *1*, *2*, rods connecting the cocks with the lever-beam.

which answered well. This engine he called a condensing engine, and so it is to-day. The piston rod was put through the cover with a gland and stuffing box, as we have to-day, but his workmanship was not so good as ours is: for want of suitable tools, he had quite a difficult piece of work to plan and make the parallel motion. The former engines had a chain over a circular piece at the end of the main beam, the piston rod being a square bar, and a little motion of the piston in the cylinder did all that was required. His piston he made of iron, with a cover or follower, with a space left to pack or caulk in plaited hemp and tallow; when the follower was screwed down it squeezed it against the sides of the cylinder and made it steam-tight. This make of piston I have packed. and it worked well in a slow-motion mine engine with low pressure. Mr. Watt had many other difficulties to be overcome; he yet had taps for admitting and letting out the steam, which were opened and shut by the motion of the main beam, not by hand, as in Newcomen's. But a better sort of arrangement had to be planned out and made; time and money were going away, and none coming in. He lived with the Doctor, and many people were talking about Watt and his new engine.

Watt's mind was fully engaged in planning a valve, in the place of the taps. His leading idea was to have the two valves connected, so that when the top valve opened to let in the steam on top of the piston, the one in the bottom will open to let it out from under the piston at the same time into the condenser. Out of these ideas grew the old Cornish D. and equilibrium valves, also the lever nozzle and foot valves for the condenser. He found his boiler not large or strong enough, because he wanted more steam and higher pressure, and the saving of more steam, also condensing it every half stroke must be done in less time. To do this he got a large tank made and put his condenser into it and covered the condenser all over the top and sides with cold water, the pipes through which the steam passed into the condenser and the condensed water came out to the feed pump, passed through the sides of the tank and the water in it, so that the steam was condensed in much less time. The water in the tank was pumped for use or waste; being warm, cold water was running into the tank to take its place; the two pumps were connected with the main beam. By this plan he had saved a large amount of steam and his engine ran much better and faster, he then put a safety valve on the boiler, and two gauge taps, and caused the fire to burn faster by enlarging and raising the chimney, but he soon found the heat he had in the furnace was 75 per cent. more than was found in the water and steam. In fact, he calculated that only 25 per cent. went into the steam, he also found it took 6 lbs. of water at 32 degrees to condense 1 lb. of steam at 15 lbs. He found that one inch of water at 32 degrees will expand into one cubic foot or 1,728 inches at 15 lbs. There are reasons for believing that these several states of matters are determined by certain conditions affecting the molecular arrangements We find that one pound of hydrogen, united with eight pounds of oxygen, will produce nine lbs. of water, giving off a considerable quantity of heat. It must be borne in mind that these two elementary substances exist as free gases, so that they can be united or used separately. The word latent means hidden and in this sense we will use it. If we take a glass flask, put it on a stand with a lamp under it, one that will give off a continuous and even heat, put into the flask one pound of water at 32 degrees; watch it taking in the heat, and in one minute, the thermometer will be, say 10 degrees higher. We will now remove the lamp and water, and put into the flask one pound of ice, put back the same lamp and watch the time it requires to melt the ice into water. It takes 14 minutes, but the thermometer marks only 32 degrees the same as the ice did. If the lamp put 10 degrees into the water from 32 degrees to 42 degrees in one minute, then the lamp must have put into the ice $10 \times 14 = 140$ degrees, but the thermometer does not show it, this is what is called latent heat concealed in the ice, which is required to bring back the ice to water. We will now put the lamp on again with the one pound of water which came from the ice at 32 degrees and watch the time it will require to boil up to 212 degrees, the thermometer says steam. It has taken about 18 minutes, or 18m. $\times$ 10° = 180° + 32° = 212°. Now without disturbing any part of it, watch the time it will require to boil all the water away, and force the steam into another flask through a connecting glass tube, 95 minutes or $5\frac{1}{2}$ times the 18 minutes the time it took to boil from 32 degrees up to 212, and yet the temperature has not risen by the thermometer above 212 degrees, 10 degrees in one minute being raised by the thermometer has become our unit 14m. $\times$ 10° = 140°. 18m. $\times$ 10° = 180° $\times$ $5\frac{1}{2}$ = 990° + 180° + 140° = 1310° -- 212° = 1098° latent heat in that one pound of ice, up to steam equal to the pressure 15 lb. atmosphere, and if we get steam up to 60 lb., 14 steam atmospheres, we will get into that steam 294 degrees or 82 degrees above 212 degrees; 8 atmospheres will give 342° = to 130° above 212°. Fahrenheit's thermometer. After laying these figures before you, 1098° latent heat and sensible heat 212° + 1098° = 1310° for one atmosphere 15 lb. or 4 atmospheres 60 lb. 1310 + 82° = 1392° or 8 atmospheres, 1392 + 130° = 1522° in steam 120 lb.

About the year 1766 little was known about the air or atmosphere. Watt was very anxious to know something more about it, for he could not burn the fuel without the air, and he wanted to know how to regulate its supply to his furnace in a practical way.

Watt's boiler is what is called the wagon boiler; the bottom sides and ends are curved inward, the top is like the cover of a wagon curved up, made strong with stays to resist the pressure of steam, say 50 lbs. It was built in with bricks, with a chimney behind; when the fuel was put into the furnace, he found it required to be of a light article so as to give a blaze to drive out some of the heavy atmosphere, the chimney and furnace being full with a weight to be overcome by the blaze. The oxygen and hydrogen in the air combined to form drops of water on the cold boiler, and until sufficient heat has been raised to change the water back again into gas, and the atmosphere is driven out of the furnace and chimney, and the bricks have taken in sufficient heat, the fire must burn; and to create a draught in the furnace and chimney the fire must burn, and a large amount of fuel consumed; the heat cannot be brought back or saved for use again, it has done its duty in lifting a weight out of the chimney. Watt complained that not more than 25 per cent. of the heat is caught in the water and steam, while 75 per cent. was gone up the chimney to warm the atmosphere. We will now learn a little from our scientific friends about it; it is a mechanical mixture, not chemically combined, and when in its purest state consists of oxygen, 20.96; nitrogen, .79, and carbonic acid gas, .04, one cubic foot at 32° with a pressure of 14 7 lbs. or 30° mercury weighs 565 1 grains, and one pound is equal to 12.387 cubic feet; it varies one grain for each degree of heat, and is 773 times lighter than water at 32°; the mean weight of a column one foot square, say 45 miles high, weight 2,124.7 lbs. $\div$ 144 = 14.7 lbs. per square inch, or $\div$ 62.5 will support a column of water 34 feet high, or $\div$ 846 lbs. (the weight of a cubic foot of mercury); it will support a column of mercury 30 inches high. If we build a chimney 60 feet high, for a boiler 60 inches diameter by 16 feet long, with tubes sufficient for an engine 24-inch cylinder, and a 36-inch stroke, the inside flue of the chimney should be at least 24 inches square. A round flue is the best; we have at the bottom of the chimney the atmosphere pressing 2124·7 $\times$ 4 = 8498·8 lbs. This great weight must be moved before we can reverse the pressure and cause an upward draught, and to do so we must burn some pounds of light fuel, and also to heat the brick in the furnace and chimney; this heat has to be kept up or maintained by the burning of the fuel, beside the heat or energy put into the steam for actual work every minute. I do not wonder at Watt being much surprised to find that his engine did not get more than 25 per cent. of the heat or energy produced from the fuel. The engineers

of to-day are complaining of the same thing, and many of them say: "We have brought the engine to a nice appearance for workmanship, economy and usefulness, but the principal part we have so far not handled successfully, viz., how to build in our boilers; are they made of the right stuff and shape, and our chimney," could not some other material be used, mica, or anything that will not give off so much heat? When this 25 per cent. loomed up in Watt's mind, he planned a different shape boiler. In one he put two large tubes in a round shell with a fire in each; but he found, if both the fires were not kept alike, it did not do justice to the boiler, and the water inside he then put in one large tube, and put the fire into it, hoping to get more heat into the steam than when the fire was outside, he found it worked better; this plan is now generally adopted in different shapes, but this plan did not, nor does it now, save the large percentage of heat leaving the boiler and going up the chimney to keep out the pressure of the atmosphere and give an upward draught or upward current not to burn, the air or oxygen, as some say, but to change the hot atmosphere and fuel into gas. A large number of new inventions have been made within the last few years, yet we are not perfect; but there is plenty of room for new plans left."

THE CONSTITUTION OF HYDRAULIC CEMENTS.

A series of experiments to determine the constitution of hydraulic cements has recently been made by S. B. Newberry and W. B. Newberry and described in a paper read before the Society of Chemical Industry. The questions which the authors have attempted to solve are as follows:—

1st. What proportions of lime must be employed for given percentages of silica and alumina in a clay? 2nd. Can a general formula be stated, applicable to all clays, which shall indicate the proportion of lime which will give the best result with each? 3rd. What effect has the presence of oxide of iron in the clay used on the proportion of lime required, and on the quality of the resulting cement? 4th. Is the presence of alkalies in the raw materials necessary to the production of good cement? 5th. Is magnesia capable of replacing lime in cement mixtures, or is it inert, as has often been stated, and how does magnesia affect the quality of the cement obtained?

The plan followed in the efforts to solve these questions was that of synthesis with pure materials, which materials were as follows:— 1st. Silica; ground quartz, in impalpable powder, containing 99.19 per cent. silica. 2nd. Alumina; C. P. precipitated, containing 99.50 per cent. alumina, .20 per cent. soda, .05 per cent. iron oxide and .25 per cent. silica. 3rd. Carbonate of lime; precipitated chalk, containing 99.7 per cent. calcium carbonate. 4th. Iron oxide; red, German C. P. 5th. Magnesia; German, C. P., containing only traces of silica, alumina and lime.

All these materials were in the form of a perfectly impalpable powder, and none of them left any residue on a sieve of 180 meshes to the linear inch. Mixtures of these materials, in calculated proportions, were made by rolling backward and forward on a large sheet of paper, then sifting three times through a 60-mesh sieve. The mixtures were then moistened with water, made into a cake, dried and broken into small pieces for burning. The burning was done in a Fletcher gas furnace, using gasoline gas as fuel.

The conclusions to which the writers are led by the above experiments may be briefly stated as follows: 1. The essential constituents of Portland cement are tri-calcium silicate, with varying proportions of di-calcium aluminate. This composition may therefore be expressed by the formula—

$$X\ (3CaO.SiO_2) + Y\ (2CaO.Al_2O_3).$$

From this formula it may be calculated that the correct proportion of lime, by weight, in Portland cement, is 2.8 times the silica plus 1.1 times the alumina. 2. Iron oxide combines with lime at a high heat, and acts like alumina in promoting the combination of silica and lime. For practical purposes, however, the presence of iron oxide in a clay need not be considered in calculating the proportion of lime required. 3. Alkalies so far as indicated by the behavior of soda, are of no value in promoting the combination of lime and silica, and probably play no part in the formation of cement. 4. Magnesia, though possessing marked hydraulic properties when ignited alone, yields no hydraulic products when heated with silica, alumina or clay, and probably plays no part in the formation of cement. It is incapable of replacing lime in cement mixtures, the composition of which should be calculated on the basis of the lime only, without regard to the magnesia present.

—The Government of New Brunswick has placed an order with the Good Roads Machinery Co., of Hamiton, for ten steel Champion road graders. The company is also shipping one of its well-known Champion rock crushers, road rollers and engines to the town of Magog, Que.

TO ESTIMATE HORSE POWER.

Editor CANADIAN ENGINEER:

(a) In the question below please inform me in THE CANADIAN ENGINEER why "3" and "2" are used, that is, where they get the "3" and "2" in the text book of which I am studying. The question is: Required the horse power of an engine having one cylinder 30 inches diameter, 36 inches stroke, making 90 revolutions per minute, boiler pressure 75 lbs. per square inch, cutting off at ¼ stroke, vacuum 26 inches, mean effective pressure on piston throughout stroke 50.5 pounds per square inch.

$$\frac{30 \times 30 \times .7854 \times 50.5 \times 3 \times 90 \times 2}{33000} = 584.1234 \text{ H.P.}$$

(b) Does black oil in a boiler destroy the scale, or does it injure it?

YOUNG ENGINEER.

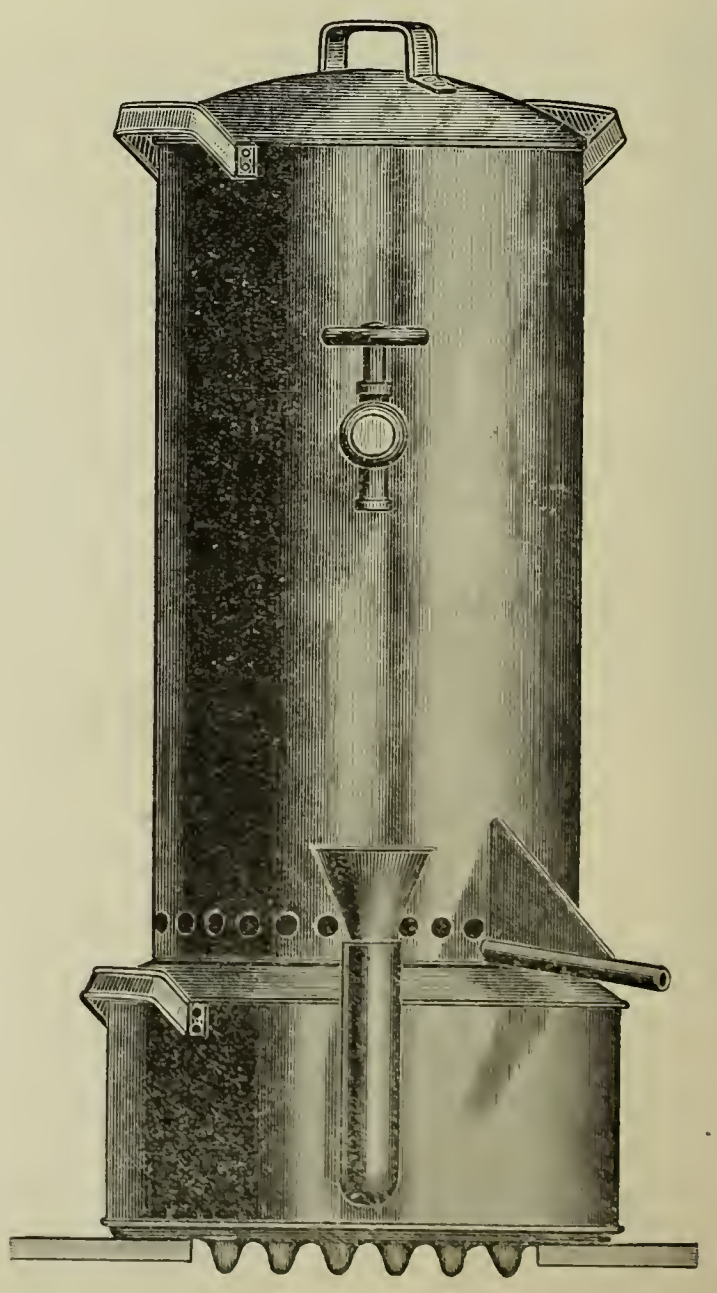
Midland, Ont.

(a) The "3" referred to here by our correspondent is the number of feet in the stroke, and the "2," is the number of revolutions per minute.

(b) The Boiler Inspection and Insurance Co. does not allow the use of oil as described. We would advise "Young Engineer" to write to some of our advertisers for information on the subject of scale in boilers.

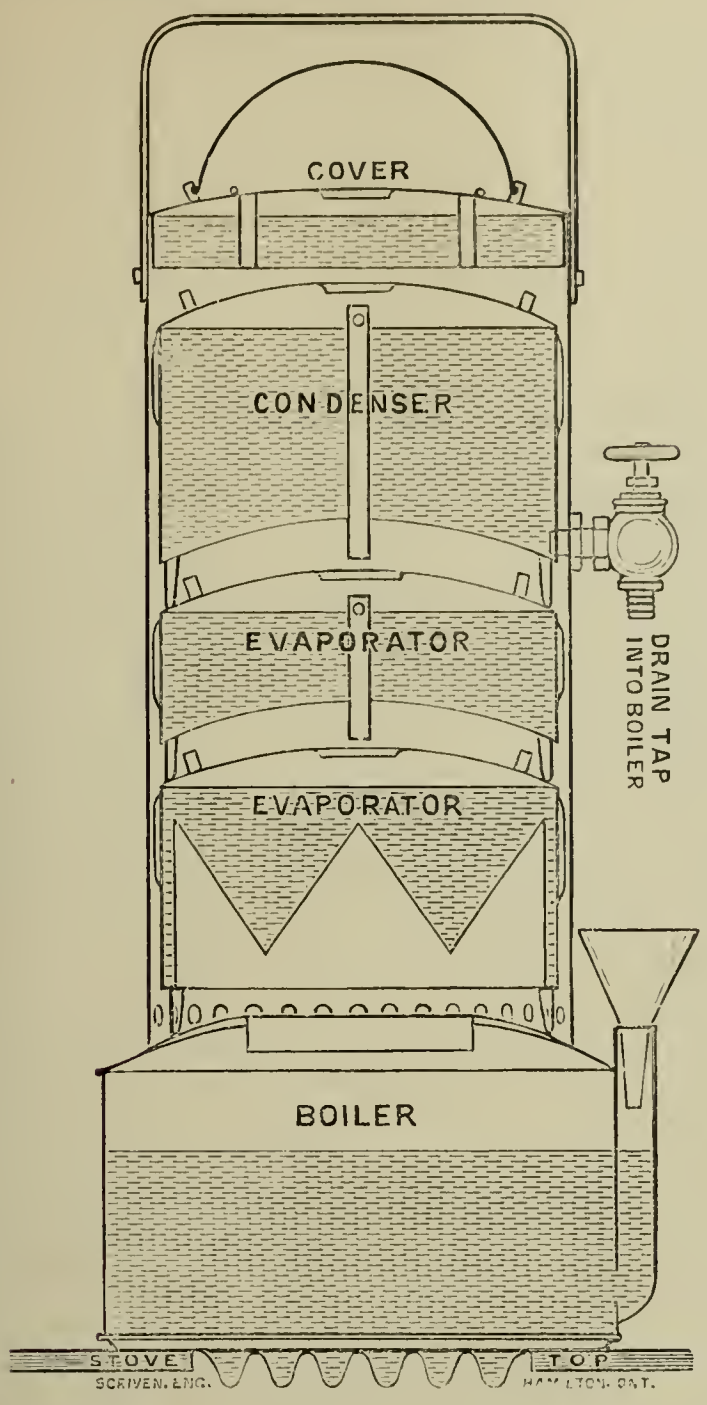
DISTILLED WATER.

The accompanying illustrations show the New-Life Water Still for producing aerated distilled water for drinking, culinary and hygienic purposes. The action of the apparatus is as follows: The water to be operated upon is placed in the lower vessel or boiler, and when boiling is placed on the kettle, and the steam passes into, around and under the evaporators, heating them to nearly boiling point, by which a part of the water they contain is evaporated and is condensed by contact with



the upper vessel or condenser; a constant current of air passing through the holes at the bottom of the condenser is carried up and sterilized by coming in contact with the steam, and, the maker claims, combines with the product, which is pure distilled water, freed from all calcareous, organic and deleterious matter. The water is pleasant to the taste, satisfying, will relieve thirst, and can be borne by a weak

stomach when "raw water" is not possible, and being divested of all injurious solids, acts as an absorbent, assisting nature to carry on the natural functions of the system.



The New-Life Water Still is the invention of J. H. Killey, mechanical engineer, Hamilton, and is protected under industrial design No. 1,360, and manufactured by the New-Life Still Co., 37 King William Street, Hamilton, Ont.

ONTARIO LAND SURVEYORS.

The sixth annual meeting of the Association of Ontario Land Surveyors was opened pro forma at the Repository of the Association in the Parliament Buildings, Toronto, on Tuesday, 22nd February, and adjourned to meet at the same place on the 8th March and the two following days. At the adjourned meeting the chair was occupied by T. Harry Jones, of Brantford, president. The attendance was larger than at any of the last three preceding years, and a lively interest in the proceedings was shown throughout.

Meetings of the council of management, board of examiners, and the standing and special committees for the association, year 1897-98, occupied the morning of the first day, the first session of the general meeting being held in the afternoon. The minutes of the previous meeting having been published in the annual report for 1897, the formality of reading them was, on motion, dispensed with. Letters were read from C. E. Gauvin, president of the corporation of Provincial Land Surveyors of Quebec; W. F. King, Dominion Astronomer; Capt. E. Deville, Surveyor General; Herbert Wallis, past president of the Canadian Society of Civil Engineers; Professor McLeod, secretary of the Can. Soc. C.E.; also from Joseph Kirk, of Stratford, an active member of the association, now in his 88th year, and from Sandford Fleming, C.M.G. A communication from the mayor of Hamilton, through E. G. Barrow, city engineer, inviting the association to hold its next annual meeting in that city, was also presented, and M. J. Butler and George Ross were appointed a committee to frame a suitable reply thereto. The president then introduced Wm. Hamilton Merritt, who exhibited a field equipment for prospectors, and explained the method of operating it. Its weight being only 27 lbs., it is easily transported, and would serve a useful purpose. The annual address of the president was next read, and a brief account of the history of the association during his term of office therein presented. V. Sankey, chairman of the council, presented the report of the council, including those of the board of examiners and secretary-treasurer, the financial statement being then handed to the auditors for verification. From these reports it was shown that the association had lost nine members by death during the preceding year, and eleven candidates had been admitted to practise at the two meetings of the board of examiners.

Reports of the committees on Publication, and on Repository and Biography, were read by Captain Gamble and H. L. Esten, the president announcing that a suitable album had been procured, and requesting that members who had not already done so would present their photographs to the last-named committee. In the absence of V. M. Roberts, his paper on "Acetylene Gas and its Uses" was read by H. H. Gibson. This paper set forth the advantages of acetylene gas over other luminants. H. D. Q. Sewell then read a paper on "Progress on the Lake of the Woods," being a supplement to a former article which he had contributed.

D. D. James read a paper by V. M. Roberts on "Water Power from the Niagara River," and discussion of various sources of water power in Ontario and Quebec for conversion into electric energy followed the reading.

After referring to a number of schemes of power development, which were more or less visionary, the writer took up the plans of the Welland Power and Supply Canal Co. to construct a power canal from the Welland River to Lake Ontario. The proposed canal will be fifteen feet deep, one hundred feet wide at the bottom and one hundred and sixty feet wide on the water line, and the slope of its sides and banks two to one, having its intake on the Welland River near the village of Montrose, and will flow through the townships of Stamford, Niagara and Grantham to Lake Ontario, being fed by the Niagara and Welland rivers. The Welland River rises in the county of Wentworth, a few miles south of the city of Hamilton, and flowing through a comparatively level country empties into the Niagara River about two miles above the Falls and is navigable for some thirty miles above its mouth. A canal or cut was made some years ago by the Dominion Government from Chippawa, a small village at the mouth of the Welland River, southerly across the northeast corner of the township of Willoughby into the Niagara River, to allow vessels bound for Welland to enter the river without risk, connecting with the Welland Canal at Port Robinson. The current of the Niagara River forces its waters through this cut, and its influence is felt some twelve miles up the Welland River. Seven miles north of the Welland River the canal reaches what may be termed the Bluff, to distinguish it from the Niagara escarpment, of which it forms a prominent and isolated portion; seven miles north of this point is Lake Ontario. Between the point of intake and Lake Ontario there is a difference in elevation of 316 feet, of which 184 feet is available at the Bluff, 66 feet in the vicinity of the Queenston and Grimsby stone road, 33 feet in the vicinity of the Niagara stone road, and 33 feet at or near the mouth of the Eight Mile Creek, every foot of which can easily and with advantage be utilized for the development of power.

The engineering features in connection with this immense undertaking are, for the most part, of an extremely simple nature; difficulties similar in all respects to those which will have to be surmounted, having already been successfully overcome in the construction and maintenance of the new Welland Canal, which lies about two miles to the west, and is a standing proof of the feasibility of the power canal. In the spring of the year when the disruption of the ice which has formed in the Welland River during the winter months takes place, the extremely swift current of the Niagara River, above the Falls, keeps the mouth of the Welland River open and carries the ice away immediately, preventing ice jams. The intake of the canal will leave the Welland River about three-quarters of a mile above Montrose bridge, at such an angle with the river as will afford protection from ice coming down stream, and crossing a small knoll, enters the bed of a creek flowing into the Welland River about half a mile lower down, and follows its course for about one mile and a quarter, thence almost due north across the height of land to the bluff, crossing under the Allanburg cut-off of the Grand Trunk Railway and the St. Catharines and Niagara Central Railway, and over the Great Western Division of the Grand Trunk Railway, thence following the general course of the Eight Mile Creek to Lake Ontario.

The deep cut on the proposed canal will be about 65 feet, the slope of sides of cut and canal will be two to one in earth, and have a batter of one in twelve in rock. A short distance south of the crossing or aqueduct over the Great Western Division of the Grand Trunk Railway a regulating weir will be constructed of first-class masonry. The aqueduct will be similar in all respects to that on the new Welland Canal where it crosses the same railway about one mile to the west, being composed of a masonry tunnel, covered with puddle clay properly tamped and rammed to form the bed and banks of the canal. A storage basin or reservoir and head race will be constructed

at the bluff, which presents about six thousand feet of almost perpendicular sides, in the form of a semicircle, down which the water will be conveyed through steel tubes to the turbines. From the bluff to Lake Ontario the cutting will not be heavy, the canal being formed alternately in cut and fill, masonry dams and sluiceways being built at the point of power development.

At the opening of the evening session the president announced that a committee of the Can. Soc. C.E. desired to confer with the association, represented by a committee, on the subject of the proposed incorporation of civil engineers in Ontario. Messrs. Sankey, Butler, Niven and Gaviller were then appointed to discuss the matter with the representatives of the civil engineers, and report to the association before the close of the annual meeting. An interesting report on "Exploration" was then read by E. Stewart, chairman of that committee, and discussion ensued, after which a paper on "Forestry in its relation to Land Surveying" was read by T. H. Southworth, Provincial Clerk of Forestry, who showed the immense importance of attention to this subject to the future of Canada. His statements were heartily endorsed by several speakers, M. J. Butler adding facts and statistics in support. The Economic Resources of the Hudson Bay District was the subject of a paper by J. W. Tyrrell, whose experience and observation in the far north made him an undoubted authority on many of the particulars as to the wealth of that part of the Dominion, so little known to the great majority of Canadians. Capt. J. D. Williams presented a paper on "Some Causes of Loss in Gold Mining in Ontario."

Wednesday morning session opened with an announcement by the president that the publishers of THE CANADIAN ENGINEER had kindly presented to the association a number of copies of its issue of February, 1898, containing a biographical sketch of Wm. Ogilvie, the most prominent member of the association. A. W. Campbell, chairman of the committee on engineering, then read a comprehensive report of the works which had come under the notice of that committee during the year.

Capt. W. F. Van Buskirk read a paper on the Sewerage Purification Works of Worcester, Mass., and replied to several questions brought up by members in that connection.

The capacity of the works is now upwards of 15 million gallons per day, providing for the entire dry weather flow of the sewers. The lime used for precipitation is slaked and mixed with water in two tanks, 8 x 6 feet each, the mixture being agitated by compressed air delivered by perforated wrought-iron pipes placed in the bottom of the tanks. The milk of the lime is delivered to the main outfall sewer by an iron pipe entering at a point about 100 feet above the screen chamber. Sulphate of alumina was formerly used with the lime, but was discontinued. The quantity of lime used is about 900 lbs. per million gallons of sewage, or 40 tons per week, at a cost of $6 per ton. This quantity is much less than is generally used, owing to the fact that the sewage of Worcester contains at times large quantities of iron salt from wire works, which is run into separate tanks and used gradually in connection with the lime. After receiving its charge of lime the sewage passes through a screen chamber, where all large substances are removed; thence flows down a mixing channel with rather a rapid fall to the channels between the settling tanks, whence it is directed, along with a small amount of the sewage containing the iron salts, into the various tanks by means of movable flash boards. The sewage passes slowly from one tank to another, the solids in suspension gradually sinking to the bottom, until it reaches the last one in operation, whence it flows out over a weir to a channel which conducts it to the river. The effluent looks bright and transparent, but appears to contain a considerable quantity of lime in solution at times, as the stones with which the outlet channel is paved were coated with lime. From one to three tanks are "cut out" each day, and after being allowed to stand quiet for a short time, the clear liquid is drawn off by means of hinged floating arms from pipes provided with valves passing through the walls of tanks. The sludge deposited in the bottom of tank is then run off to the sludge well through masonry channels located under the sewage channels between the tanks. It is then pumped from the well by a Shone ejector, the air for which is compressed by power from a water wheel driven by the effluent from the tanks of the main outlet. After leaving the well the sludge is deposited on beds, where the water is gradually drained off. The sludge has not been utilized to any great extent, but it is reported to be growing in favor, and presses are being put in which will leave the material in a form that will permit of economical handling or disposal.

Notwithstanding the fact that nearly all of the suspended matter is removed, the town of Millbury entered action a short time ago to compel the city of Worcester to further purify its sewage, and in consequence of such action the city employed Samuel M. Gray and Dr. Drown to make a report on the plant. They have recommended that the effluent from the works be further purified before being discharged into the river, and for this purpose an area of ten acres is being prepared for sand filtration. There is a little doubt, however, whether this will abate the nuisance or not, as the river bed and mill ponds are still covered with the organic matter deposited before the works were put in operation, and during heavy storms since that time when the whole of the sewage was not passed through the tanks. The report above mentioned affords further evidence of the fact that purification by chemicals is an incomplete process and that the lime and organic matter remaining in the effluent may give trouble when discharged into streams and small bodies of water. The experience of Worcester is particularly interesting as being in all respects similar to the experience of England, where it is found that notwithstanding the many improvements in settling tanks and in the methods of applying chemicals, it is not possible to produce effluents of sufficient purity to be discharged into the smaller rivers without causing complaints, and as a consequence the effluents are generally subjected to further treatment by rapid filtration through gravel coke, or some such material. Chemical precipitation, it is true, may in some cases give a degree of purification sufficient for the conditions which obtain, but the writer is of opinion that it will in most cases prove less expensive to treat sewage by rapid filtration through gravel, aided by a current of air and when the conditions demand complete purification, the effluents can be filtered in the ordinary way at a very high rate per acre. It has been shown by experiments conducted by Board of Health of the State of Massachusetts, that rapid filtration through gravel or coke gives an effluent comparable in all respects with that obtained by chemical precipitation under the most favorable circumstances, and has the advantage that the sludge is disposed of, as it is consumed in the pores of the filter. Recent experiments in England confirm the conclusions of the Massachusetts Board of Health, and we may expect in the near future to find many of the chemical plants supplanted by more scientific and less costly methods.

A paper on "Evidence," that mysterious bugbear of candidates for admission to practice as land surveyors, was presented by M. J. Butler, whose training and practical experience in this connection fitted him to the task, and in the subsequent discussion it was suggested that Mr. Butler prepare a text-book on the subject, so far as it related to land surveying.

Sudbury waterworks was the subject of a paper prepared by L. V. Rorke, and, in his absence, read by D. D. James. This paper formed a valuable addition to the collection of articles on waterworks already published in the annual reports. Professor C. H. McLeod, secretary of the Canadian Society of Civil Engineers, having arrived from Montreal as a representative of that body, was welcomed and introduced by the president. The report of the Committee on Polar Research was read by J. W. Tyrrell, chairman.

The first order of business for the afternoon session was a paper by Jas. Hutcheon on "Specifications," containing many valuable hints.

A. P. Walker then read his paper on "The York Street Bridge," extracts from which appeared in the last issue of THE CANADIAN ENGINEER. "An Illustration of the Necessity for Accurate Descriptions" was the subject of a paper by George Ross, who gave the history of an important question of title to lands at Point Abino, Lake Erie, which had been the cause of much litigation. P. S. Gibson, well known to all surveyors admitted within the last thirty years, next read a paper on "Assessment Plans," describing the requirements of such plans and exhibiting a specimen sheet of a set recently prepared by him for the township of York.

The report of the Committee on Land Surveying, with Question Drawer, was presented by M. Gaviller, chairman, with answers to several knotty points sent in by members who appreciated the advantage of having an advisory board of experienced practitioners, whose duty it is to give the benefit of their opinions to any who seek them. A list of cases compiled by M. C. Schofield, an active member in the 80th year of his age, after 55 years of practice, was referred to the incoming committee for classification, and a question as to the position of shore or bank of a lake or river from which a road allowance is laid off, was also held over. The report of the Standing Committee on Topographical Survey was read by L. B. Stewart in the absence of the chairman, Otto J. Klotz. This committee continues its work, notwithstanding the lack of present results, but its efforts will eventually be crowned with success. M. J. Butler presented a description of sand cement, the product of recent improvements in manufacturing methods. This paper may be more fully discussed in a later issue. The evening was devoted to the annual dinner, that function which has done so much to promote a closer acquaintance among individual members, and which this year eclipsed all previous occasions in point of attendance and enjoyment.

The session of Thursday morning opened with the presentation of the report of auditors, which was read by H. L. Esten. A paper on the Kinburn Swamp Drain, prepared by F. W. Farncomb, was read in his absence by the secretary, and described a case where the judi-

cious investment of a few thousand dollars had resulted in the reclamation of waste lands, the value of which had amounted to several times the amount of the sum expended. H. J. Bowman read a paper entitled Arbitrators and Witnesses, dealing with the respective attitude which should be taken by each. In the absence of W. M. Davis, his paper on "The use of Field Tile for Large Drains," was read by A. S. Code. The writer showed the superiority of tile drains for several reasons. The following table gives approximately the comparative cost of open and tile drains of various depths:—

COST PER ROD.

Depth.	Open Drain.	Field Tile 6 in.	8 in.	10 in.	12 in	14 in.	18 in.
3 feet	$1 08	0 90	1.20				
4 "	1.80	0.96	1 26	1.86	2.19	3 00	
5 "	2.52	1 27	1.60	2.00	2.40	3 60	5.00

It would appear from the above that for depths up to 5 feet, and for sizes of tile up to 12 inches, the tile drain has the advantage, considering only first cost, and taking all things into account field tile of any size capable of carrying off the water, and for any depth, are cheaper than an open drain. In deciding on the size of tile it is not necessary to provide a capacity that would be ample for a culvert, neither is it safe to calculate on a drain having twelve months in which to dispose of the annual rainfall. In this latitude a rainfall exceeding one inch in twenty-four hours is exceptional, so that this quantity may reasonably be taken as a basis for our calculations. Not more than one-half the rainfall can be depended on to reach the trunk drain, a proportion which decreases as the area of the watershed increases. If the water can be removed within forty-eight hours, as a rule, no damage to the crops will result, therefore a trunk drain that will convey about 900 cubic feet of water per acre in twenty-four hours will be ample for ordinary drainage; lateral drains will require a greater capacity depending on the facility with which the rainfall reaches the tile.

Tile over twelve inches in diameter should not be less than two feet in length, as they can be laid more evenly; they should be particularly well burned, and moulded from the toughest clay; many qualities of clay, which make fair tile of small size, are totally unfit for hose of large diameter. The thickness should increase from one inch for 12-in. tile to $1\frac{3}{4}$ inch for 18-in. tile. Two factors of vital importance in drainage are: perfect alignment and grade; the curves should not have a less radius than 60 feet. An accurate grade can best be obtained by means of "boning rods;" that is, by placing two bridges across the trench about 300 feet apart, the tops being adjusted so that a line joining the top of one with the top of the other will be parallel with the grade line. A rod equal in length to the distance of this line from the grade line is then used to obtain the exact elevation of each tile; this method is especially advantageous when working in quicksand. Catch basins or manholes should be placed about 1,000 feet apart to admit of easy inspection of the drain; they should have a pit 18 inches below the grade line for the purpose of intercepting sand; they also provide a convenient means of connecting lateral drains Wherever possible, these catch basins should be placed at crossings of fences.

In accordance with the usual practice, the report of the committee on entertainment was taken as read, and ordered to be printed in the annual report. Professor McLeod addressed the association on the subject of proposed incorporation of civil engineers in Ontario, and explained its objects and its relation to the position occupied by land surveyors. The discussion on the report of council was begun, and lasted the remainder of the session. In the afternoon the discussion on the report of council was continued, and by-laws numbers 45 and 46 were ratified. Under motions, the papers on "Unrecorded Original Field Notes," by J. J. Murphy, and "Lake Erie Survey," by Otto J. Klotz, also the report of the committee on drainage, were taken as read, and ordered to be printed in the report.

Since the date of the meeting the balloting for the election of officers for the ensuing year has resulted as follows:—

President—P. S. Gibson, elected by acclamation.
Vice-President—H. J. Bowman "
Sec.-Treas.—T. G. Van Nostrand "
For Council of Management—F. L. Foster and J. L. Morris.

The report of the committee appointed to confer with representatives of the Can. Soc. C.E., was presented by Major Sankey. A cordial vote of thanks was tendered the retiring president for the manner in which the duties of that office had been fulfilled by him, after which the meeting adjourned.

The Hess Metallic Furniture Company, Niagara Falls, Ont., has begun building and will probably be the first company to use electric power developed on the Canadian side of the river for manufacturing purposes.

MANUFACTURE AND USE OF SAND CEMENT.

The following extract from a paper by C. B. Smith, McGill University, Montreal, was read by the author at the recent meeting of the Canadian Society of Civil Engineers in Montreal:

The use of sand cement has increased in Europe, and particularly in Denmark (where it was invented), during the past five years, and it has been tested by several American engineers, with satisfactory results, and has been used in the proportions (1 to 1) to 3, in the concrete for the foundations of St. John's Cathedral, New York, in which 3,000 yards were used, and in other places.

The advantages claimed for the material are, that where great strength is not required, mortars will be more dense, stronger, and will work more smoothly on the trowel, in which a portion of the sand has been ground together with the cement, before use in the mortar. Another claim is that the cheaper grades will replace lime mortar in plastering, as it will set and dry quicker, and also, again, that in dock walls a very dense concrete can be produced which will prevent the destructive percolation of sea water.

Tests made at St. John's Cathedral foundations gave the following results:—

(1) Sand cement (1 to 1) Concrete. 2 sand, 3 gravel — Compression. 1 week—2,144 lbs. per sq. in. 2 weeks—2,312 lbs. per sq. in. 4 weeks—2,588 lbs. per sq in.

(2) Sand cement Mortar. (1 to 1) sand cement. 3 sand. — 1 week's tension 156 lbs. 2 weeks' tension 188 lbs. 4 weeks' tension 200 lbs.

(3) Portland cement. 1 cement. Mortar, 1,500 bbls. 3 sand. — 1 week's tension 137 lbs. 2 weeks' tension 170 lbs. 4 weeks' tension 179 lbs.

The paper concluded with a description of the plant at Glen Falls, N Y., where tube mills and flint pebble balls are used in grinding, and a statement that the American sand-cement output is ground very fine (5 per cent. residue on 180 mesh sieve), the tests will show higher results than those in the table which is added, giving tests made in Europe on sand cement mortars of various proportions.

The usual proportions in America are (1 to 1) and (1 to 6), the former competing with Portland cement and the latter with lime.

(The manufacture of sand cement has been begun in Canada by the Rathbun Co., of Napanee Mills, and the St. Lawrence Cement Co., of Montreal.)

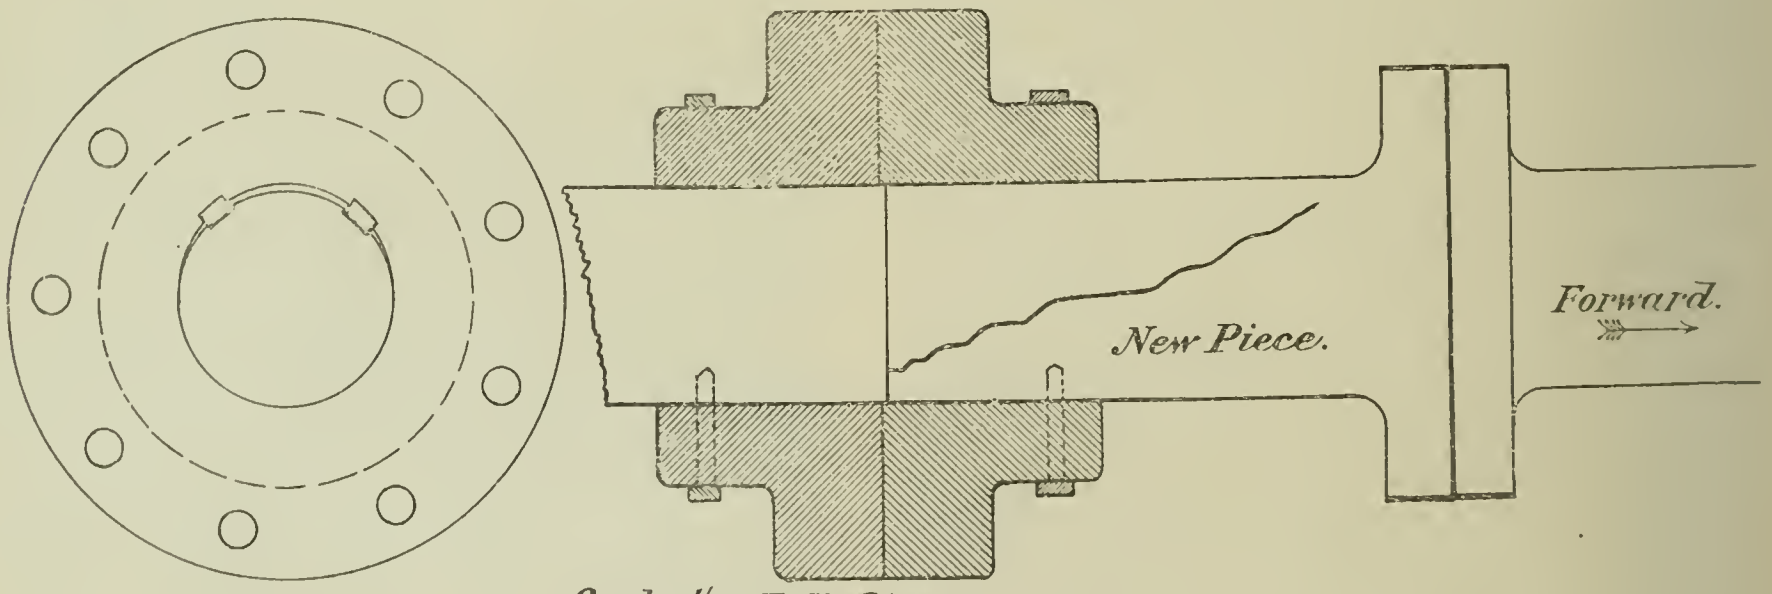
REPAIRS TO S. S. MONARCH.

The accompanying sketch illustrates the method devised by Wm. Golding, consulting engineer to Lloyds Surveyors, at the port of New Orleans, L. A., for repairing the fractured shaft of the steamship Monarch, which vessel cleared from that port on the 25th of November last, for Liverpool, carrying one of the largest cargoes ever taken from an American port, consisting of 22,535 bales of cotton: 60,000 bushels of grain; 11,200 sacks of meal; 29,068 staves and 242 head of cattle. Soon after sailing, a fracture developed in one of the 8 sections of the tunnel shaft, necessitating the return of the vessel to New Orleans, where she arrived without assistance on the 30th of November, 1897. To renew and remove the shaft would require several weeks' time, necessitating the removal of a large portion of the large cargo. It was therefore decided in the interest of all concerned, to repair the shaft in place, and make the renewal at port of destination.



Scale 1/16 Full Size.

As shown in the sketch, the shaft was cut off in place, while the vessel lay at anchor in the river; the new piece was forged, turned and fitted; the large coupling cast, bored and turned, and the entire work completed in less than 12 days after the vessel's return; the success of the undertaking is attested by the arrival of the vessel in due time, at port of destination. The value of vessel and cargo was estimated to be $1,250,000.00.

PROSPECTOR'S OUTFIT.

Editor CANADIAN ENGINEER:

A frend of mine who intends to go prospecting before long through the Omenica district, asks if it would be advisable to take an inexpensive outfit for testing ores, with a suitable textbook on same.] He knows nothing whatever of analysis or assaying. Will you kindly give me your opinion on the matter, and if you think it would be judicious for him to take an outfit such as mentioned above, what would it need to consist of and what work on the matter would you recommend as the most suitable, that is to say, the simplest and most practical? By giving information asked for you will greatly oblige

Yours truly,
SUBSCRIBER.

British Columbia Southern Railway,
Wardnor, B.C., 5th April, 1898.

[ED.—We would advise your friend to secure a copy of either "Gold and Silver Ores," by W. Hamilton Merritt, or "Pocket Mining Manual," by J. H. Chewett, both of which will be found in the book list on page III. of this paper. The following is a list of articles required for field work, it being taken for granted that the prospector is already in possession of a rough knife for scratching minerals, a pocket compass and a small magnifying glass:—

Sampling—1. "Mixing cloth," or smooth waterproof sheet, 4 feet square. 2. Brush, broad (varnishing brush). Panning—3. Gold-pan, Russia iron (not to be used with quicksilver) 4. Iron mortar, 5 in. by 6 in., and pestle. 5. Sieve, brass wire, 40 mesh, in tin dish with cover. Pan-Amalgamation.—6. Two gold pans, one ordinary iron, the other graniteware. 7. Nitric acid, strong, in 2 oz. glass-stoppered bottle. 8. Mercury, 1 lb. in bottle. 9. Sodium, 1/8 oz. in bottle, with naphtha. 10. Hand-scale, "Traveler's letter and parcel balance," weighing 1/4 oz. to 12 ozs., for weighing mercury and pulp. 11. Balance, hand scale with sliding weight on beam, very sensitive, from 0.1 to 5 grains, for weighing beads of bullion and weighing out charges for quantitative blow-pipe assay. 12. Mercury retort, small, Russia sheet-iron 1 1/2 x 1 3/4 inches, or small cast iron retort, with cover and pipe to collect mercury. Also sheet of Russia iron 8 inches square (with hole for supporting the Russia iron retort in the centre) for quartering when sampling. 13. Porcelain dish, and porcelain thimble, small, for parting in. 14. Graniteware cup and saucer, small size. 15. Brass wire sieve, 60 mesh. 16. Wooden pestle. 17. Sheet lead, pure, 2 ozs. 18. Sheet silver, pure, 1/8 oz. 19. Borax glass, ground, 1 oz., in deep round tin box. 20. Soda, 1 oz, in deep round tin box. 21. Litharge, 4 ozs., in deep round tin box. 22 Bone-ash, 2 ozs., in deep round tin box. 23. Paraffine lamp, tin, with 1/8 lb. paraffine. 24. Blow-pipe. 25. Two clay pipes, one mounted for cupelling, the other for heating mercury. 26. Charcoal, 3 pieces, sawn square. 27. Pincers for small buttons. 28. Steel anvil, 1/4 x 1 1/2 x 2 inches. 29. Small piece thin asbestos card. 30. Hammer, small 31. Magnet. 32. Smooth-headed bolt, for making cupels in clay pipe This outfit will determine the value of free milling ores as low as of any economic value; it will enable the proportionate yield in concentrates to be qualitatively tested as to their precious metal contents. Quantitative determination of concentrates outfit. 33 Plattner's ivory button scale. 34 Clay crucibles, 1 doz. 35. Clay capsules, 2 doz. 36. Fletcher's blow-pipe furnace with side hole. 37 Camel-hair brush. 38. Flour, 1/4 oz (?) in tin box. 39. Methylated spirits 1/4 pint. 40. Common salt, fine, 1/2 oz, in tin box 41 Nitre, 1/2 oz, in tin box. 42. Spirit lamp, tin. With the above mentioned outfit free-milling ores can be tested, and value determined as low as $1 50 per ton for gold ores, and much lower for silver ores, if desired Also the value of the concentrates, or of melting silver ores, can be approximately estimated. The weight of the outfit is about 20 lbs.]

CO-OPERATIVE SETTLEMENT.

Editor CANADIAN ENGINEER:

SIR,—The prospect of early work on the Georgian Bay and Ottawa Ship Canal, together with the agitation for a railway to James' Bay, give point to a suggestion I made regarding a co-operative settlement by men of intelligence and some financial means. I know a point where these enterprises must intersect, if the shortest route, with the best land adjacent, are considered important. The shore of the Georgian Bay is rockbound round the north, and admission must be sought where a bay or navigable river penetrates the coast range of granite or Huronian mountains. Spanish River, Parry Sound, Cutler and Thessalon, are examples of such entrances; while French River, White Fish, Blind and Mississagrea Rivers are barred by falls at their mouths. Now a navigable bay, penetrating to the arable land, and accessible in all weathers, is a very desirable point from which to start a colonization road. If, in addition, unlimited water power, cheaply controlled, be added, with a choice of routes through good country for

50 miles to form a Hinterland, then I hold an ideal location will be selected. The port and settlement would be on Laurentian territory, with iron, mica, granite, galena and gold, as minerals to be expected; its rear would be the contact with Huronian, on the same lines as the Wahnapitae gold formation. The probabilities would amount almost to a certainty, that paying mines would be one of the assets of the colony; that the port would be a distributing point on the James Bay railway; and that a good farming background would give stability and weight to the commercial, manufacturing and mining features of the enterprise.

As suggested before, an electric railway to progress with the onward wave of settlement, should be a prominent feature. Supposing Sudbury to be the first objective point on the James Bay route, our line would run obliquely to N. E. of it, and act as an auxiliary rather than a rival. While the first cut of pine has been taken off the district, the hardwood, pulp timber and bark is yet untouched, and might amount to a valuable consideration. A company with, say, 1,000 shares of $100 each, to be sold at par only, and employing only shareholders (if enough offer) to do the work; with no speculators, and no drones; with a store at which all supplies are furnished at cost; and with all mechanical appliances furnished by the members at special rates; with electric light, power, carriage, and even board, at rates to meet actual outlay, the conditions of settlement would be so much superior to the general conditions of pioneers that colonization would be shorn of its chief discomforts. If you could leave the crowded streets, vile odors, competitive battle, dress parade, and taxes of city life; but carrying school, church, library, literary and musical socials with you, into a healthier climate, with more profitable employment, abundant fuel, fruit and flowers—in short a natural life—who would hesitate to embark in it? You cannot choose your company in city life—you may in the country.

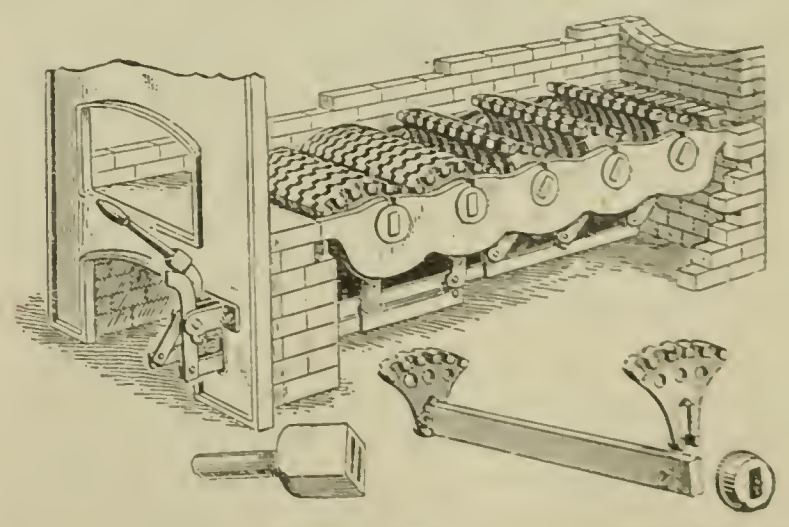
CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

The eleventh annual dinner of Hamilton No. 2, C A S E., was held in the Commercial Hotel, April 7th. There was the usual large attendance, and the evening passed most pleasantly. The menu was excellent, and was done full justice to before the toast list was presented by the chairman, R. Mackie. During the evening music was interspersed by Messrs. Jardine, the Eleon Club, J. R. Dixon, Stanley, Hastings, A. Child, W. G. Blackgrove, F. Mitchell, and D. Marentell. J. Bain acted as accompanist. The dinner committee was R. Mackie, chairman; Joseph Ironside, secretary; P. Stott, W. R. Cornish, W. Stevens, R. E. Chillman, R. C. Pettigrew. The toast list was as follows: The Queen; Canada our Home, responded to by A. Hartwell; Mayor and Corporation, responded to by Alds. Hernside and Pettigrew; Manufacturers, responded to by J. McGlauchlin, of Toronto; Educational Interests, responded to by J. S. Williams; Executive Head, responded to by E. J. Philip, A. M. Wickens, of Toronto; Sister Associations, responded to by Messrs. Mooring and Dixon, of Toronto; Hamilton No. 2, responded to by R. Mackie; The Ladies, responded to by A. P. St. John; Host and Hostess, responded to by Messrs Moxey. A pleasant feature of the evening was several selections by the gramaphone, operated by Mr. Morrice.

ROBERTSON'S SHAKING AND DUMPING GRATE BARS

The shaking and dumping grate bars of which the accompanying engraving gives an idea are manufactured by Jas. L. Robertson & Sons, 204 Fulton St., New York, who are successors to the Heine & Robertson Co. The firm is very favorably known to the trade, not only in the United States, but in Canada as well. The makers state that nearly seven years use,



under conditions of unusual severity, has demonstrated their efficiency and durability, and the recent changes in design, tending to greater strength, enable them to promise even more satisfaction in the future. The grate is composed of a series of replaceable leaf castings, a best quality wrought iron cross bar, protected from the heat, and durable bearings in which, it is claimed, friction is reduced to a minimum. Frames for seven sections and under are made without truss.

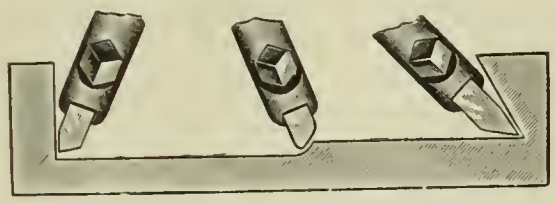
L'ASSOCIATION DE SECOURS MUTUELS DES INGENIEURS MECANICIENS.

This association held its annual meeting on the 25th ult. under the presidency of Ephrem Valiquet. Associated with him were Louis Gayon, Factory Inspector; Alex. Bonin, Prof. at Laval University; J. A. Rodier, and the association's legal adviser. The election of officers resulted as follows: President, Ephrem Valiquet; 1st Vice-pres., Henri Beauchamp; 2nd Vice-pres., Mathis Guimond; Treas., Wm. Gendron; Fin. Sec., Eteinne Leroyer; Corresponding Secretary, Alex. Blair; Asst. Sec., Jos. Guimond; Trustees, Magnus Lessard, Arthur Coulombe, Alphonse Provost; Conductor, Arthur Alix; Doorkeeper, Telesphore Leclaire; Employment Agent, Ephrem Valiquet; Delegates, Gendron, Denis, Coulombe. After the

elections many good speeches were made, tending to emphasize the fact that the objects of the association were mutual benefit and improvement, not what is understood as labor organization in any form.

INTERESTING TO LATHE OWNERS.

A practical substitute, of self-hardening steel, for forged tools for general lathe and planer work, especially adapted for economical use, is shown in the accompanying cuts. These tools possess, the makers claim, all the good points of a forged

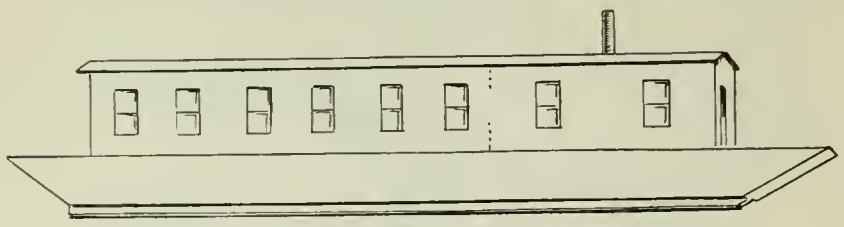


tool, and are made in variety of sizes in straight right and left hand offset, and in the form of a boring bar. The makers claim a saving of 90 per cent. tool steel, that is, one pound of steel used in a holder will do the work of 10 lbs. used in the old way, and also a saving of 70 per cent. in grinding. The Goldie-McCulloch Co., McClary Mfg. Co., Toronto Electric Motor

Co., Bertram & Sons, J. J. Stevens, and many other leading Canadian manufacturers, have adopted these tool holders. Further information can be obtained from the Aikenhead Hardware Co., Toronto.

AN OTTAWA RIVER HOUSE BOAT.

Bannerman & Findlater, manufacturers of boilers, etc., Ottawa, who recently moved into their new premises, which were rebuilt on a larger scale after the fire of last year, have recently turned out an interesting job in the shape of four lumbermen's "house boats," for the Upper Ottawa Improvement Co. These are the first iron house boats built in Canada, two of them being for use at Quio (Chats Lake), and two on the Ottawa, at Pembroke. These boats—a diagram of which is given herewith—are scow-shaped, each 5½ feet long over all, with a keel of about 42 feet; 12 feet wide at the top, and 11 feet



across the bottom and 3 feet deep. The bow tapers to an extent of about 6 feet, and the stern 4 feet. The keel is formed of a piece of timber 7 inches deep and 6 inches wide, and is protected by an iron shoe. The house stands 6 feet above the top of the hull, making a height of ceiling of about 9 feet. The kitchen and cabin occupies about one-third of the house, the rest being occupied by sleeping berths, of which there are two tiers, a tier on each side of the boat with a gangway through the middle, making accommodation for a crew of twenty-four. The house is clap-boarded with an iron roof.

NEW PLANT FOR THE WAR EAGLE MINES.

The War Eagle Cons. Mining & Dev. Co., of Rossland, B.C., have just closed a contract with the James Cooper Mfg. Co., Limited, Montreal, for a Duplex Ingersoll-Sergeant Air Compressor, and a 300 horse power Electric Hoisting Engine. The compressor is a Duplex machine of the latest type having two 24¼" by 48" air cylinders, and is ample at normal speed to furnish sufficient air for 50 drills. It will be operated by a 500 horse power motor, and in place of belting, 22 cotton ropes will be used to drive the machine. As an evidence of the size of this machine, it may be stated that the fly wheel is 20 feet in diameter and will weigh, when finished, about 25 tons. Mr. Mills, the Consulting Mechanical Engineer for Mr. Gooderham, after an extended tour through the mining districts of Montana, California and British Columbia, and after making exhaustive tests of the efficiency of the various types of compressors, decided to adopt the piston inlet type of machine as being the most economical. The hoisting engine, which is to be operated by electricity, is of 300 horse power, and has double drums arranged for two-compartment shaft, and is capable of hoisting from a depth of 3,000 feet, the normal working load being 8 tons, and the speed 1,000 ft. per minute. The motor for the hoisting engine is of the induction type, and can work up to 600 h.p. It is reversible and can run at any speed up to synchronism. Not only will the compressor be the largest machine ever built in Canada, but both the compressor and hoisting engine will be the largest machines on this continent operated by electricity, and it speaks well for the enterprise of Rossland mines, that they are foremost in the field of up-to-date machinery. The motor for the compressor is a 400 h.p. synchronous machine and will run at 200 revolutions per minute. The electrical equipment is being furnished by the Canadian General Electric Co., of Peterboro, Ont., and the machinery when completed will aggregate about 15 carloads. The plant is to be delivered on cars in ten weeks from receipt of order, and should be on the ground inside of three months. The power will be derived from the works of the West Kootenay Power Co. The War Eagle mine has now been proved to a depth of 625 feet, giving an estimated amount of ore in sight of $3,500-000. In one place the vein is exposed to a width of 50 feet, giving an average assay of $25. The force of miners is to be increased to 50 men.

CANADIAN ELECTRICAL ASSOCIATION.

At the last meeting of the Executive Committee of the Canadian Electrical Association, it was decided to hold the convention on Tuesday, Wednesday and Thursday, the 28th, 29th and 30th of June, in Montreal. The headquarters of the association during the convention will be at the Windsor Hotel, where the business sessions and the annual banquet will be held. The draft programme, recommended by the local committee of arrangements, with some slight amendments, was adopted, and is as follows:

First Day.—Executive meeting 9.30 to 10 a.m.; session, 10 a.m. to 1 p.m.; session 2 to 5 p.m.; 7.30 p.m., trip round Mount Royal by special Park and Island cars, afterwards ascending Incline railway, to lookout on mountain to view the city under illumination.

Second Day.—Session, 9 to 12, noon; cabs and busses from Windsor Hotel at 1 p.m. to visit: (1) Bell Telephone Company's new building; (2) Street Railway Company's power house; (3) power house and works of the Lachine Rapids Hydraulic & Land Co., returning to city at 7.30 p.m.; 9 p.m. annual banquet of Association at Windsor Hotel.

Third Day.—Session, 9 to 12 a.m., election of officers and visit to McGill University; 1.30 p.m., visit to Royal Electric Company's lighting station and factory, then by special G.T. train to visit the works of the Chambly Manufacturing Company at Chambly.

A number of very interesting and instructive papers relating to various phases of electrical work have been promised and are in course of preparation. Negotiations are in progress with the object of securing special transportation rates to enable a large number of the western members to participate in the proceedings of what will undoubtedly be a very pleasurable and instructive occasion.

THE E. & D. WHEEL.

The factory of the Canadian Typograph Co., manufacturers of the celebrated "E. & D." bicycle, is pushed to its full capacity. The Globe, in a recent notice of this wheel, says: "The bearings of this bicycle were invented in Canada in 1895, by Canadians, and the wheel is built only in Canada and exported throughout the world. It is the first and only Canadian bicycle that has successfully entered the United States market, and Canadians have a particular reason for feeling proud when it is known that this wheel commands a higher price than any wheel in the United States, and that it is sold there at an advance of from $15 to $20 above its price in Canada. Perfection of movement has always been the particular theme of this company, and they have every reason to feel proud of the reputation they have gained in so short a time by their wonderful hub. We are in-

formed that they have never yet supplied a cone or ball for this bearing, nor ever been asked to replace one. They defy their competitors or others to show a cone out of their wheel, no matter how long it may have been in use, that shows the slightest indication of wear. They also challenge the public to destroy one of their bearings or to make it bind, no matter how tight it may be screwed up. The wheel is guaranteed to run the year without being oiled or cleaned, no matter how many miles it is ridden, or how much dirt is encountered. The bearings also are guaranteed against wear for three years. They never require to be adjusted or interfered with. The Typograph Company has a special model this year, which includes the Doolittle automatic brake. Simple back pedalling applies the brake, and when once applied, the foot can be removed and the brake remains, while forward pedalling immediately releases the brake, so that the rider has complete control of his wheel, whether his foot is on the pedal or not. This model also includes a new gear case, composed of aluminium and celluloid. It can easily be removed and leaves the chain and sprockets at all times exposed to view. It is also so arranged that the back wheel can be adjusted without in any way disturbing the case.

BOILER EXPLOSION AT ORILLIA.

The boiler at Miller's tannery, Orillia, Ont., exploded on Good Friday evening, wrecking the building and causing damage to the extent of over $5,000. At the close of the holiday, the fireman, thinking to get an early start in the morning, filled the furnace with wood ready for lighting and in that condition left the place. It is supposed the wood took fire from the heat of the bricks from the previous firing, and that the safety valve had become stuck, preventing any release of steam. An idea of the wreck may be gained from the accompanying illustration. Two fragments of the boiler narrowly missed a train passing at the time. The crown of the boiler went through a barn a great distance from the scene, and the angle at which it struck

the building showed that it must have been thrown at least half a mile high. In view of the terrible treatment received by the crown, at the hands of the steam fury, it is remarkable how gently it handled the window sash shown in the left foreground of the picture. This sash was used as a skylight, and was fixed in the roof right over the boiler. This sash was found after the explosion in the position shown, with not a single pane of glass broken. The mere concussion of air broke the glass in several houses near by, and how this window sash with all its contents passed through the explosion unshattered is a phenomenon. One theory is that it was lifted as on a cushion of steam, and so let down flat to the ground. Even so, its safe descent is remarkable, and how it was torn out of its frame, in the first place, without breaking the glass, is still more remarkable.

It is decided that Agincourt is to be the location of the instrument of the Magnetic Observatory now in the Queen's Park, Toronto. William Menzies will be in charge. The building to be erected will consist of a circular stone underground chamber of some 30 feet in diameter, topped by a brick structure for the making of absolute determinations. In the underground room, the needles of vertical force, horizontal force and the declinator will make photographic records of the earth's magnetic currents. The new building, it is estimated, will cost in the neighborhood of $4,000, and that the utmost care will be exercised in its erection can be seen from the fact that every stone put in the walls must be tested to ascertain that it contains no iron to disturb the delicate working of the magnetic instruments within.

Industrial Notes.

Belleville, Ont., will buy a road roller.

The new high school, at Fergus, Ont., will probably cost $5,000.

St. Thomas, Ont., will spend $36,000 on school buildings this summer.

The town of St. Cunegonde, Que., wants another bridge over the Lachine Canal.

Tenders are called for the Victoria Hospital, London, Ont., which is to cost $70,000.

A Y.M.C.A. building, to cost $6,000, is to be built in St. Catharines this summer.

Knox Church, Stratford, Ont., is to be altered and remodelled at a cost of $7,000.

R. F. Watts, Ottawa, Ont., is said to have invented a new roller boat which is rectangular in shape.

Sarnia, Ont., proposes to bonus a paving brick manufactory which would use shale from Alvinston, Ont.

Sheldon & Son, of the Aylmer, Ont., Iron Works, have received a large order for windmills from Australia.

J. Bloom, who ran a sawmill at North Glencoe, Ont., was killed by falling on the circular saw, March 31st.

The I.O.O.F. will build a town hall in Essex, Ont., one flat of which is to be leased by the town at $300 per year.

Lefebvre & Co., St. John's, Que., are putting an acetylene gas machine into their vinegar and canning factory.

Park, Blackwell & Co., Toronto, have decided to erect a new pork packing establishment. It will cost $100,000.

The city engineer of London, Ont., has proposed a dyke to surround the suburb of West London at a cost of $150,000.

The pumping plant at the high level reservoir, Montreal, requires a new large high duty pump, which will cost about $70,000.

The contract for the new Verity Company's buildings, Brantford, Ont., was let to Havill & Whitham, Brantford, for $50,750.

S. S. Jewett & Co., brass founders, Buffalo, N.Y., have no intention of establishing a brass foundry at St. Thomas, Ont., at present.

Ridgetown wants W. E. Hall's furniture factory to move there from Galt. It has been offered a bonus and exemption from taxation.

The Simpson-Merner Furniture Co., Berlin, Ont., of which Senator Merner is the head, will erect a large addition to its works this summer.

Extensive improvements are to be made in St. Andrew's Church, Perth, during the coming summer. It is estimated that $10,000 will be expended.

The Sarnia Gas & Electric Light Co. has closed a contract for a modern gas producing plant, with the Western Gas Construction Co., of Fort Wayne, Ind.

E. F. Head, architect, Rat Portage, Ont., has been instructed by the school board to prepare plans and specifications for a twelve room school building.

J. E. Belcher, C.E., County Engineer, Peterboro, Ont., has prepared plans for the Mudlake bridge, partly embankment and partly floating, to cost $25,000.

J. W. Meyers & Co., Listowel, Ont., have decided to make $7,000 improvements to their flour mill. They will also build an elevator, 30 x 48 feet, this summer.

The incorporators of the Dominion Aluminum Roofing Company, Montreal, are: Abel Huot, Lucien Girard, Antoine Collard and Nap. Plessis, contractors.

The Leviathian Belting Co., Boston, Mass., has opened an office in Quebec, at No. 101 St. John St., and has appointed L. H. Gaudrey as its representative in the district.

At Hartland, N.B., it has been decided to form a joint stock company to build a bridge. The government will be asked to guarantee the bonds for a term of 15 years.

Another pulp mill is to be built on the Sissaboo River, near Weymouth, N.S., as the Fredericton Reporter notes that a new company has been organized for the purpose.

The Ottawa Board of Trade has taken action that may soon lead to the establishment of a Technical School, in order to encourage the manufacturing industries of the city.

The Metallic Roofing Co., Toronto, has just supplied one of their metal ceilings for the chapel of the Central Prison. These goods are particularly adapted for church work.

The Rat Portage Lumber Co., of Rat Portage, Ont., is expending in the neighborhood of thirteen thousand dollars in special improvements on its planing mill, saw-mill, etc.

The London, Ont., water commissioners have decided to continue the conduit to Byron, so as to tap Griffith's springs, which will add 250,000 gallons per day to the city's water supply.

Two spans of the Saskatoon bridge on Qu'Appelle, Long Lake and Saskatchewan Railway, were carried away by ice April 19th. In the meantime crossing will be effected by ferry.

Dartmouth, N.S., has a proposition before it to bonus a pulp mill to have a capacity of 20 tons per day. The promoters have secured options on suitable water power and land in the town.

The Donoghue Bros., Kingston, will erect, on their property, near the Montreal Transportation Company's elevator, a grain elevator with a capacity of between 80,000 and 90,000 bushels.

M. A. Cleveland, who has a contract on the public works, Cardinal, is now starting in on his rock work, after placing an order with this same company for one of their latest model Sergeant drills.

F. G. B. Allen, supt. of the Cement works at Napanee Mills, Ont., has fitted up a laboratory in his residence. The office has also been moved to the station, the old office and laboratory turned into an engine room.

Some Ottawa people are looking for a suitable location and water power, to build a large pulp mill. If suitable site can be secured, with good shipping facilities, building operations will be commenced early this summer.

The respective county authorities of Norfolk and Simcoe, Ont., have decided to recommend that a new steel bridge, 150 feet long, be constructed over the Big Otter Creek, between the townships of Bayham and Middleton.

A man who has large experience in steel and iron manufacture, is coming out from England to take hold of Thos. Doherty's latest invention in that line, and will remain in Canada a couple of months at least, it is said.

The Manufacturers' Committee of the Brantford City Council propose a general exemption from all but school taxes, upon all machinery and tools for local manufacturing industries, employing a given number of hands.

The McClary Manufacturing Company, London, Ont., is filling an order from a San Francisco house for $7,000 worth of stoves, tin and graniteware, for the Yukon trade. The goods, which will fill six cars, will be shipped direct from London.

The Niagara Falls Metallic Furniture Company, Limited, has been incorporated with a capital of $24,000. The officers are as follows: Pres., R. P. Slater; Vice-pres., W. Phillips; Sec., J. E. Stephenson; Treas., Dr. E. T. Kelliham; Manager, Wm. Hess.

W. Harris, Day's Mills, Algoma, Ont., offers power and mill-site free, with small bonus, to any responsible party who will erect any kind of wood-working, furniture or handle factory. Any amount of good hard wood and other timber near the site.

John F. Stewart, for many years manager of the James Stewart Manufacturing Company, Woodstock, has been succeeded by his brother, Adam A. Stewart. J. F. Stewart still retains his interest in the business, and the presidency of the company.

The James Cooper Mfg. Co., Limited, Montreal, has just completed shipment for Larkin & Sangster, contractors, Iroquois, Ont., of four Lidgerwood double cylinder, double drum hoisting engines, with five Sergeant drills, and quarry bar outfit.

The molders in the Waterloo Mfg. Co.'s foundry, struck recently for an advance of 25 cents per day; as no notice was given the management of dissatisfaction beforehand, the strikers did not receive any consideration, but were replaced by outside labor at once.

J. Zryd, G. Zryd, O. Zryd, J. E. Schmidt, Annie M. Zryd, Hespeler, Ont., have been incorporated as the Zryd Gas Machine Company, of Hespeler, Limited, to manufacture, buy, sell and deal in acetylene gas machines and parts thereof, capital, $5,000.

The village of Andover, N.B., has been recently incorporated and proposes to put in a fire protective waterworks system of 2¼ miles of piping. C. L. B. Miles, C.E., has been engaged to make the necessary surveys and plans. Tenders will be shortly called for.

L. McGlashan, manager of the Ontario Silver Works, Humberstone, Ont., intends making a large addition to the factory. The new wing will be about 100 x 40, brick. A large dynamo and gas engine will be among the plant to be placed in the new addition.

The Council of Westmount, Que., have passed the by-law authorizing the loan of $350,000, to be used in the construction of parks and other public improvements, among which are a contagious disease hospital to cost $15,000, a dump and incinerator to cost $10,000, and municipal buildings, $25,000.

The People's Heat & Light Co., of Halifax, is increasing their plant for greater facility in handling materials at the power house, and has placed an order with the James Cooper Mfg. Co., Montreal, for a standard Lidgerwood 30 horse power link motion and friction double drum cylinder hoisting engine, which will be shipped at once.

Andrew Bell, C.E., Almonte, Ont., on behalf of a company, has asked the Carleton Place town council for a franchise to put in a system of waterworks similar to the one in Perth, Ont. He wants a similar franchise for Almonte, and the company he represents is said to be willing to spend $100,000 in each town to put in a first-class system of waterworks.

The following have obtained incorporation under the style of the Jacques Cartier Pulp Company, to carry on the business of pulp and paper manufacturing; acquire water powers on the Jacques Cartier river and elsewhere, develop electricity to be supplied for motor and lighting purposes, etc., etc.: E. Goff Penny, R. Archer, Wm. Strachan, W. Currie and R. Law, Montreal.

The dynamite factory of the Ottawa Powder Co., situated on the Chelsea Road, on the Quebec side of the river, about four miles north of Ottawa, was recently blown up. No person was injured or killed. The damage to the plate glass in Ottawa amounted to over $2,000. The cause of the explosion is not known. This is the third time that the factory of the Ottawa Powder Co. has been blown up.

The Wm. Hamilton Mfg. Co., Peterboro, has in hand the entire equipment of a sawmill, which the C.P.R. is erecting at Cool Creek, about 60 miles west of McLeod, N.W.T., in the Douglas Fir District. The equipment of the mill is of the most modern type, and it will have a capacity of 100,000 feet in ten hours. The entire plant comes from the Hamilton shops, including a battery of six boilers, handsaws, etc.

James E. Smith, who at the time of the Windsor, N.S., fire, had charge of the reed and rattan department of the Windsor Furniture Mfg. Co., has entered into a partnership with H. B. Murphy, of the firm of Wood & Murphy, and will commence manufacturing reed and rattan goods. The factory will be in Falmouth, N.S., near the mill of F. H. Manning, who is now erecting a building, and will supply the new firm with power, water, etc.

The Dominion Plumbing and Supply Association was formed in Montreal recently, letters calling the meeting being sent out by Geo. Booth, of Toronto. The object of the association is for the better protection of the trade. The officers elected were: J. Reid Wilson, Montreal, president; A. A. McMichael, Toronto, vice-president; W. H. Wiggs, Quebec, second vice-president; while the Executive Committee will be formed of Col. F. Massey, W. Greig, A. Lariviere, J. M. Taylor and H. Wright.

THE PUBLISHERS.

The Ontario Board of Health recently approved the plans for the village of Hintonburg, which is putting in a system of sewage; for Mount Forest and Port Colborne, which are putting in waterworks; and Rat Portage, which is also constructing waterworks and extending its sewage system.

The James Cooper Mfg. Co., Limited, Montreal, has just secured an order for an additional plant for the Regina Gold Mine, Limited, of Rat Portage, consisting of duplex cross compound condensing Ingersoll-Sergeant piston inlet compressor, ten drills, battery of boilers, pumps, heaters and all necessary connections to install plant complete. The first shipment in this contract has now gone forward.

Thompson & Co., Sherbrooke, Que., have agreed to install, in Lennoxville, a system of waterworks. The water will be taken from Haskell Hill, about half a mile distant. The reservoir will have a capacity of 400,000 gallons, and will be about 125 feet above the town. The contract will have to be finished within eight months from the date of the signing of the contract. There are to be twenty hydrants placed in the streets for fire purposes. A number will be placed in and about the buildings and grounds of Bishop's College.

The James Cooper Mfg. Co., of Montreal, has completed shipment of contract for complete mining plant entered into with the Montreal-London G. & S. Dev. Co., to equip the Dufferin property, at Salmon River, N.S. This plant consists of a duplex cross-compound condensing Ingersoll-Sergeant piston inlet air compressor, eight drills, battery of three boilers, one 50 horse power and one 40 horse power Lidgerwood link motion and friction double compartment shaft hoisting engines and all necessary piping and connections to install plant complete ready for operation.

Some important experiments were recently made in the Workman Engineering Building, at McGill University, by Profs. Adams and Nicholson, of the Faculty of Applied Science. They consist of taking filings or turnings of brass, copper, tin and other metals, and by means of pressure, securing therefrom solid bars of metal, differing very little in appearance and strength from castings. The machine used in these experiments brings to bear upon the filings and shavings about 78,000 lbs. pressure to the square inch, and this has the effect of welding them into a solid bar of metal.

The Canadian Photo-Engraving Bureau is extending its premises, having leased another flat in the building in which it is located, at 16 Adelaide St. West, Toronto, and is now making extensive alterations and improvements in it. Part of this extra flat will be used as an office, giving them greatly increased accommodation, and the balance as a photo department. It is their intention to establish a first-class photograph department, fully equipped for all kinds of commercial photography, such as landscapes, buildings, interiors (daylight or flashlight), and articles of any kind. The combination of the photograph gallery with the photo-engraving business, is a good one, and will be a great advantage to those having cuts to be made, where the photos have to be taken from the article or building.

Prof. Callendar, who has just resigned from the staff of McGill University, has designed a platinum electrical resistance thermometer, capable of measuring temperature to the ten thousandth part of a degree. The extreme delicacy of the instrument makes it a valuable aid in securing accurate observations of the temperature of lake and river water, during the various seasons of the year, as no thermometer is available for such minute measurements. A long series of observations of the temperature of the St. Lawrence has been made this winter by the McGill professors, in all of which the new instrument has been used. By its aid it has been found that the greatest deviation that takes place in the winter during the ice-forming period, is only about one thousandth part of a degree. Prof. Callendar's invention is, undoubtedly, of great interest to the scientific world.

The Wm. Hamilton Mfg. Co., Peterboro, Ont., has recently completed the engines for a large stern-wheel steamer, for J. A. Mara, Vancouver, B.C. The wheel is 19 feet in diameter with buckets 9 feet long, which take a dip of 30 to 34 inches; on either side of the wheel the cranks are placed. The crank shaft is a steel forging 10 inches in diameter and 24 feet long. The engines are aft on each side. The boiler is placed well forward, about 70 feet from the engines. The engines run 30 revolutions per minute, and the boiler pressure will be 160 lbs. The power developed is calculated at 2,300 h.p. Speed, 18 miles per hour. The cylinders are 17 inch and 6 foot stroke. The connecting rods are 24 feet from crosshead to the crank pin, and are built up of plates. From the head of the cylinders to the outside of the paddle wheel will be 48 feet. The boiler is of the locomotive type, 62 inches in diameter, by 7 feet long. In the barrel are 212 inch tubes, 14 ft. long. The furnace is 7 ft. by 5 ft. by 6 ft. high inside. The Hamilton Company has now in hand a duplicate set of these engines, building to the order of the C.P.R., for one of their boats running from Vancouver to Fort Wrangel.

Of interest to engineers throughout Canada is the advent of a new company known as the Canadian Chemical Compound Co. The principal promoters are A. M. Wickens, E. J. Philip, D. J. LeRoy and Richard Jeffrey, all of Toronto. The new company will manufacture boiler compounds, of which it has three special brands, suited for waters of different character. As the public may well be sceptical of the virtues of a patent medicine which claims to cure all diseases, so engineers may doubt the efficacy of any one boiler compound which claims to be suitable for waters of every locality. The Canadian Chemical Compound Co. not only has three different brands suited to the waters of most localities in Canada, but they undertake in exceptional cases to prepare special compounds where the water is heavily charged with any unusual foreign element. The three special brands will, however, remove scale from almost any class of water, and leave no injurious effect on the boilers. Messrs. Wickens and Philip have long made a study of this subject, and anything that they would place on the market will be received with confidence by steam engineers of Canada, among whom they are so well known. The new company has issued a very neat booklet, which will be sent free from its offices in the Temple Building, Toronto.

Electric Flashes.

The Vankleek Hill Electric Company, Limited, has received an Ontario charter for incorporation.

The electrical pumping plant in the Perth, Ont., waterworks is reported to be giving complete satisfaction.

The Canadian General Electric Co. has sold to Alex. Dobson, of Beaverton, Ont., a standard 20-K.W. Edison dynamo.

The Rathbun Co., Deseronto, is building a freight motor for the Longue Pointe section of the Montreal Island Belt Line Railway.

Larkin & Sangster, contractors, Iroquois, Ont., have purchased from the Canadian General Electric Co., a 35-light arc dynamo with lamps.

The Canadian General Electric Co. has put in the last of the four 4,000-light single-phase alternators ordered by the Toronto Electric Light Co.

The Halifax Tramway Company has installed two 5,000-light monocyclic alternators from the works of the Canadian General Electric Company.

The Canadian General Electric Co. is furnishing to the Linde British Refrigerating Co., Montreal, two 50 h.p. and one 15 h.p. Induction motors.

The British American Corporation, Vancouver, B.C., has ordered a 100-light dynamo, with search lights and engine, from the Canadian General Electric Co.

The Canadian General Electric Co. has closed a contract with the corporation of Port Arthur for a railway car body equipped with G.E. 1,000 motors.

The Consolidated Electric Co., Victoria, B.C., is preparing to develop a large amount of power at Goldstream near the city. The plant will cost about $100,000.

The B. C. Bullion Extracting Co. has made a contract with the Canadian General Electric Co. to supply a 100 horse-power synchronising motor, and a 50 horse-power induction motor for their works, which are about a mile and a half from Rossland, B.C.

An Electrical Engineers' Association for the maritime provinces was formed in Halifax last month. James Waddle, Charlottetown, P.E.I., was one of the delegates present.

The London, Ont., Electrical Construction Company is said to be willing to establish itself in Kingston, Ont., if exemption from taxes, free site and free water are granted.

The Canadian Pacific Navigation Co., Victoria, B.C., has purchased from the Canadian General Electric Co., for one of their steamers, a multipolar direct connected set with marble switchboard.

Price Bros., Quebec, have ordered from the Canadian General Electric Co. a complete electric and steam plant for the Assiniboine Block, Winnipeg, Man. The generating plant will have capacity for 400 lamps.

Hamilton City Council has voted to buy from the Hamilton, Chedoke & Ancaster Electric Ry. the Becket mountain drive and quarry for $12,000. This makes the construction of the road almost a certainty.

D. Maxwell & Sons, St. Mary's, are installing an electric plant for lighting their factories, and have purchased for the purpose a 350-light Edison dynamo, manufactured by the Canadian General Electric Co.

The Manitoba Gas & Electric Light Co., of Winnipeg, has ordered from the Canadian General Electric Co., a 6,000-light direct-current generator to run at 150 revolutions a minute, also a 125-light brush arc machine.

The Canadian General Electric Co. has closed a contract with the Laurentide Pulp Co., at Grande Mere, Que., for two 55-kilowatt moderate speed direct current dynamos with marble panels and instruments complete.

As announced in another column, the chair of electrical engineering, in McGill University, is vacant by the retirement of Prof. Carus-Wilson. Applications for the position will be received by the secretary up to 20th June.

Letters patent have been issued to the Toronto Electric Motor Company, Limited, capital $50,000. Those incorporated are: J. C. McLachlan, H. S. Albertson, G. McLachlan, J. W. Thompson and W. A. Turbayne, Toronto.

The Toronto Railway Company is refitting its long Yonge St. cars with G.E. No. 800, four-motor equipments furnished by the Canadian General Electric Company. The old two-motor equipments did not furnish enough tractive force.

The Peoples Electric Co., of Windsor, Ont., is making extensions to the electric system and has placed an order with the Canadian General Electric Co. for all the material required, including over 1,000-light capacity in transformers.

The Windsor Hotel Company, Montreal, is making extensive alterations in the electric installation, and has ordered from the Canadian General Electric Co. two 1,000-light slow-speed multipolar generators with marble switchboard panels.

The Montreal Street Railway Company has determined to construct the Cote des Neiges line, and the management is waiting the return of James Ross from England to commence operations, which it is expected will be by May 15th.

The authorities of the Longue Pointe Asylum, Montreal, are building a branch street railway to connect the institution with the Montreal Belt Line, and the Canadian General Electric Co. is supplying a 110 K.W. steel-frame railway generator to furnish power.

The London Electric Co. is putting in a 6,000-light 300 K.W. alternator to extend the sphere of their lighting operations, and two 160 K.W. direct-current, direct-connected generators for power. These machines are being supplied by the Canadian General Electric Co.

The Ingersoll Packing Company has contracted with the Canadian General Electric Co., Limited, for a complete installation of incandescent lamps, arc lamps, motors and generator for their factories at Ingersoll, Ont. The generating apparatus will consist of a 25-kilowatt 125-volt multipolar dynamo of the C.G.E. Co.'s latest and most approved type.

The Cataract Power Co., Hamilton, is making progress with its power development at Decew Falls. The works are expected to be completed in eight or ten weeks.

The Ontario Rolling Mill Co., Hamilton, is rapidly rebuilding the works recently destroyed by fire ; they intend installing the most modern system of electric lighting throughout, and have placed an order with the Canadian General Electric Co., for one of their latest types of multipolar direct current dynamos having a capacity for 300 lights.

W. Doherty & Co., Clinton, Ont., have commenced work on their new factories, which they expect to have completed early in May. The new works are to be lighted throughout by electricity, and for this purpose they have closed a contract with the Canadian General Electric Co. for a 500-light dynamo, two 10 h.p. motors, and all wiring material required.

The Hon. John Haggart, W. A. Allan, A. Charlebois, Sir Sanford Fleming and R. G. Code, of Ottawa, are applying for incorporation as the Canadian Electric Water & Power Co., of Ottawa, capital $10,000, to establish waterworks and manufacturing electric machinery and electricity for the purposes of light, heat and power in the cities and towns of Canada.

J. R. Scott, an enterprising citizen of Napanee, has closed a contract with the Canadian General Electric Co. for a 100 K.W., 4,000-volt, three-phase generator of the revolving field type, for the purpose of supplying light and power to Napanee from a water power 8 miles distant. He will also supply light and power to intermediate points such as Napanee mills, Camden East, and Newburgh.

The Montreal Cotton Co., of Valleyfield, Que., has just placed an order with the Canadian General Electric Co. for two 600 h.p. three-phase generators, to be direct connected to turbines. This installation is a duplicate of the generators installed by the C.G.E. Co. over a year ago, and which have given entire satisfaction. With these four generators and station apparatus the company will have one of the most modern power stations on the continent.

The Electric Reduction Co., of Buckingham, Que., is putting in a 1,000 h.p. three-phase generator for electrolytic work. This machine is wound for a potential of 60 volts, and is of the revolving field and stationary armature type. It runs at 160 revolutions per minute, 75 volts, and is direct connected to a water-wheel. The equipment is of the same type as that furnished by the Canadian General Electric Co. to the West Kootenay Power & Light Co.

The Hamilton and Lake Erie Power Co. has been given by the government the power to increase its capital stock from one to three million dollars, and extension of time for three and six years respectively to begin and complete the work. Hon. W. R. Scott appeared for the promoters, and said the works were costing a very large sum and an extension of capital was needed. When completed there would be a great reduction in the cost of power in that district.

The Hon. J. Lanctot, M.D., of St. Henri; A. G. Bourbonniere, A. Christin St. Amour, Montreal; L. A. Sauve, St. Ignace du Coteau du Lac, and A. McNown, Cornwall, have applied for incorporation under the name of "La Compagnie d'Electricite de Soulanges." The object of the proposed company is to operate telegraph and telephone lines in the county of Soulanges, with a capital stock of ten thousand dollars. The principal place of business will be at Coteau Landing.

The Manitoba Gas & Electric Co., Winnipeg, is making very extensive alterations and additions to its plant, and have placed an order with the Canadian General Electric Co. for a 300-kilowatt alternating generator of their monocylic design, and one 125-light brush arc dynamo to be direct connected to vertical engine. The Canadian General Electric Co. is thoroughly overhauling the outside construction work, and equipping the system with their standard type H. transformers throughout.

The date printed on address label of this paper signifies when the Subscription is paid to. If you are in arrear, kindly favor us with remittance. Subscriptions are payable in advance.

THE PUBLISHERS.

L. A. Campbell, for several years chief engineer of the Canadian General Electric Company, has been appointed general manager and electrical engineer of the West Kootenay Power and Light Company. Under the superintendence of Mr. Campbell, this company has already installed 2,000 horse power for delivery to Rossland, B.C., and has a waterway developed for 7,000 horse power altogether. The company supplies power to the celebrated War Eagle mine, whose plant is referred to elsewhere in this issue.

At a meeting of the Royal Electric Engineering Society, held a short time ago, K. B. Thornton, of the Royal Electric Co., read a paper on Alternating Current Arc Lamps; also at a meeting of the society, held March 31st, W. F. McLaren and R. F. Morkill, of the Royal Electric Works, read a paper on Alternating Current Motors. Mr. Dix, of the same Company, will read a paper at the next meeting, April 14th. The society are holding their meetings in the Board Room at the Royal Electric Co.'s General Offices, which has been very kindly loaned by Mr. W. H. Browne.

It will be remembered that in the action taken by the Montreal Street Railway Company against the Montreal Park & Island Railway Company, on account of loss from the fire at the exhibition ground buildings, when a number of cars leased by the Street Railway Company to the Park & Island Company were destroyed, the Superior Court granted the Street Railway Company $5,786 damages. From that judgment there were two appeals, one from the Street Railway Company itself, claiming that the amount granted was too small, and another from the Park & Island Company, asking that the action be dismissed. The Court of Appeal held that there had been no fault or negligence on the part of the Park & Island Railway Company or its employees and the damage to the cars had been caused by an irresistible cause. Under those circumstances the judgment of the court below must be reversed, and the action of the Street Railway Company must be dismissed.

The Toronto Electric Motor Company's business has again out-grown its premises, though two or three extensions have been made since it was established in Adelaide St. The Company is now building a factory of its own in Pearl St., and expects to move into its new premises in the course of a month. Among the orders awaiting delivery on the books are 100 arc lamps, for the Citizens' Light and Power Co., Montreal; a 5 horse power motor for T. H. Dryden, Toronto, and one of similar size for R. Anderson, Ottawa; two 30 horse power motors for the Mail and Empire, a 30 k.w. generator for the elevator at Coteau Landing (owned by John S. Metcalfe & Co., Chicago), a 60 k.w. generator for R. E. T. Pringle, Montreal, and a 130 k.w. generator, and a 140 horse power motor for the T. Eaton Company, Toronto, the last-named being the sixteenth machine furnished by this firm to the great departmental store. Another interesting installation is a 200-light dynamo and a 20 k.w. power generator for the Rat Portage Lumber Company, to be used for lighting the mills and for operating an electric locomotive for a tramway running throughout the Company's yard.

Mining Matters.

The Dominion Coal Co. is building a large number of cars.

Oil is reported in the township of Brooke, near Alvinston, Ont.

The Canadian Mining Institute has applied for a Dominion charter of incorporation.

Another oil well at Point Edward, Ont., is completed, and its pumping qualities tested with satisfactory results.

The Hamilton Board of Trade has asked the Dominion Government to impose an export duty on nickel ore.

The British Columbia Smelting & Refining Co. has transferred the smelter at Trail, B.C., to the C.P.R. Company.

The Iron Mask Mine, Rossland, B.C., is putting in one of the Jenckes Machine Co.'s smaller size hoisting engines.

The discovery of an extensive deposit of valuable iron ore is reported to be made in the Laurentides, about eighty miles from Montreal, on property owned by Adolph Trempe, brother of the Montreal detective of that name.

British Columbia business still continues brisk. The Jenckes Machine Co. reports the demand for mining machinery quite active.

The Rossland branch of the Jenckes Machine Co. recently placed a No. 5 Cameron pump with the Center Star Mine, also a No. 6 with the Monte Cristo.

The Dominion Government has authorized the issue of free miners' licenses at the summits of the Chilcoot and White passes, at the head of Lynn Canal.

The receipts from the corporation natural gas plant last year in Leamington, Ont., were $10,406.14, and the expenses in connection with the plant were $770.

Large coal beds are said to have been located on or near the line of the proposed Glenora and Teslin Lake Railway, about fifty miles from Telegraph Creek.

The Boundary Creek District, of British Columbia, is coming forward, and it is very likely that a number of large development plants will be put in during the coming season.

E. E. Pettigrew, of Winnipeg, has placed an order with the Jenckes Machine Co., Sherbrooke, for a five-stamp mill complete, with thirty-five horse power engine and portable boiler.

The property of the Non-Magnetic Asbestos Co., of Point au Chene, Que., is advertised for sale in another column; the sale to take place on the 15th. The property is reported to be a very valuable one.

The Canadian Rand Drill Company has sold to R. O. Jennings, Fort Steele, B.C., a big power pump for use in the hydraulic mining plant which the Jennings Company is installing on Brewery Creek.

Texada Islands, off Jervis Inlet, B.C., will, it is said, soon have a smelter. The plant was ordered by the Van Anda Company, which has brought ten cold-copper properties on Texada to an advanced stage of development.

The Kenneth Mining and Development Co., at Rossland, B.C., is making an addition to its equipment in the shape of a 7 x 10 double-cylinder hoisting engine, with boiler and all appliances complete, furnished by the Jenckes Machine Co.

Vivian & Sons, Swansea, Wales, and the Elbois Metal Company, of Burryport, South Wales, have, it is said, as the result of the success of trials, decided to come into the British Columbia market for the purpose of smelting all kinds of ore and furnace products.

John Fenton, farmer, who lives near Ryckman's Corners, Ont., has had natural gas on his farm for several years, sufficient to heat and light the house, and recently a big flow of gas was struck at a depth of 200 feet. The previous flow was from a well 460 feet deep.

The Brookfield Mining Co., North Brookfield, N.S., has bought a hoisting engine and other machinery from Austen Bros., for use on the Dunbrack property, recently purchased by them. They propose to sink a shaft about 200 feet and then drive levels to thoroughly test the belt.

Development still continues on the Golden Cache Mine, Rossland, B.C. The company claim to have a narrow claim streak, running $200, with the rest of the ledge containing average values to pay $1 net. Contracts, amounting to $40,000, have been let for electric and hydraulic plants.

The Electric Reduction Co., of Buckingham, Que., is proceeding to develop the water-power, and as a first step has placed an order with the Jenckes Machine Co., Sherbrooke, Que., for a pair of 45" crocker turbines, to be installed complete with wheel cases, draft-tubes, governor, etc.

The emery found on the East shore of Lake Winnipeg has been pronounced by experts to be of the very finest quality. The deposits are known to extend over an area of twenty-five square miles. About 50 claims have been taken up. Deposits of aluminum and quicksilver have also, it is said, been found.

The proposed British Columbia Chamber of Mines has been established. The initial meeting was held at Vancouver, B.C., with Dr. Selwyn, F.R.S., in the chair, and representatives of mining interests from different districts present. Twenty-five signed as representative and five as associate members. The following were elected an executive committee: W. A. Carlyle, W. Pellew Harvey, W. White, H. Abbott, H. Cohen, Barclay Bonthrone, A. St. G. Hamersley, F. S. Taggart, C. C. Bennett, Dr. Selwyn and Dr. Bell-Irving.

The B. C. Goldfields Co., of Toronto, has recently placed an extensive order with the Jenckes Machine Co., for a ten-stamp battery complete with two vanners, two ore feeders, grizzly, Blake-Marsden crusher, and all the various apparatus making up a complete modern milling plant. The outfit is to be delivered at Nelson, B.C.

The British Columbia Copper Co., Anaconda, B.C., have just contracted with the James Cooper Mfg. Co., Limited, Montreal, for the installation of an Ingersoll-Sergeant ten-drill compressor plant, complete with ten drills, battery of boilers, Lidgerwood hoisting engines, pumps, heaters, and all necessary equipment to make the plant complete.

Dr. J. B. Porter, Professor of Mineralogy at McGill, is now in the mining regions of Nova Scotia, at the head of a large field prospector's class from McGill University. They will examine portions of Cape Breton, and the Guysborough gold fields, remaining in the east about six weeks. The class was sent out through the generosity of W. C. McDonald.

Dr. Gilpin, inspector of Nova Scotia mines, has sent to the Provincial Government a report on the result of his recent official trip to Whycocomagh Cape Breton. He says the gold discoveries are very valuable but does not go into minute details. Dr. Gilpin found very rich quartz and also free gold in sand taken from the bed of the Whycocomagh River.

The annual report of the B. C. Dept. of Mines has been presented to the Legislature. It shows that the total output of minerals, including coal, in 1897, was valued at $10,455,268, an increase of 40 per cent. over the previous year's yield. The gold value was $2,646,000; silver, $3,272,000; lead, $1,390,000.17; coal, $2,648,562. West Kootenay produced to the value of $6,765,000.

An oil well has been struck on the farm of Benjamin Boothroyd, about a mile from Thamesville, Ont. F. Carmen is the proprietor of the well. One night there were two hundred barrels pumped in twelve hours, and the average yield is still almost equal to that. There is another well on the adjoining farm, the property of John Herbert, which promises to be almost equal.

An Edmonton despatch says that letters to Rev. Father Husson and R. Hardisty confirm the report that "Cayuse" Graham has come across the mountains from the head waters of the Pelly River, and has struck pay dirt at ten to twenty dollars a day. Graham crossed the Upper Liard, west of the mountains, in November, and reached Fort St. John on February 1st, with horses and sleds.

A letter recently received by Bishop Pascal, of Prince Albert, from Rev. Father Ancel, stationed at Hay River Mission, in the North-West Territories, states that a party of prospectors have found rich gold deposits on both Hay and Buffalo rivers, emptying into Great Slave Lake. These rivers are located about 700 miles north of Prince Albert on the Regina and Prince Albert route to the Klondyke.

F. C. Flannery, secretary-treasurer of the Toronto Smelting Company, proposes erecting at Madoc, Ont., a plant to treat the mispickel ores of Hastings County; he recently showed samples of the arsenic produced at the company's small test-mill at Millbridge, Ont. The company has now a ten ton water jacket smelter, which is to be put up at Madoc, and started as soon as possible. The company will treat the mispickel ores for arsenic with gold and mineral wool as bi-products.

Free mining machinery to the value of $128,780 was admitted into Canada during the fiscal year ended 30th June last, having been supplied by the following countries: Great Britain, $9,266; Denmark, $2,451; Germany, $2,864, and the United States, $114,239. Of this amount Ontario got $30,308; Quebec, $24,812; Nova Scotia, $21,520; New Brunswick, $452; Manitoba, $695; British Columbia, $44,087, and the Northwest Territories, $5,897. In addition to these should be mentioned diamond drills purchased in the United States of a value of $19,880. Among the dutiable articles we find 184 steam pumps, valued for duty at $24,860.

THE PUBLISHERS.

Marine News.

The contract for repairs to the steamer Rosedale was awarded the Caledonia Iron Works, Montreal. The repairs will amount to about $28,000.

The Geological Survey of the United States has ordered a large number of canoes from the Peterboro Canoe Company for the use of exploring parties in Alaska.

The propeller Persia has been bought by W. A. Geddes, Toronto, and Jacques, Montreal, Capt. Crangle and J. H. G. Hagarty having sold to those gentlemen their interest.

Clinton B. Sears is considering the matter of raising the bones of the old steamer Winnipeg, of the Collingwood line, which lie in shallow water at the bottom of Duluth harbor.

The Canadian General Electric Co is equipping, with incandescent light, a steamer being built by the British Columbia Iron Works, for the Klondyke Exploration Co., Limited.

The Canadian Pacific Navigation Co. has purchased from the Canadian General Electric Co., a 125-light, incandescent plant for a steamer running from Vancouver to the Stikine River.

The British Columbia Iron Works Co. has ordered a 6-kilowatt incandescent dynamo from the Canadian General Electric Co., for a steamer which it is building for the Klondyke trade.

The Canadian Development Co., Victoria, B.C., of which H. Maitland Kersey is Managing Director, has ordered three incandescent light equipments, for new steamers, from the Canadian General Electric Co.

The Hudson Bay Company has placed a contract with the Canadian General Electric Co. for two 100-light incandescent equipments, to go on their new steamers, running from Vancouver and Victoria to the Stikine River.

Messrs. Cameron, Collingwood and Burton, of Barrie, have arranged to place the City of Collingwood and the Majestic on the route between Collingwood, Owen Sound, Sault Ste. Marie, Port Arthur, Fort William and Duluth.

The Allan Line has given a contract for the construction of a ten thousand ton steamer, to be known as the "Sicilian" and a sister ship to be the "Tunisian." The length is five hundred feet, beam 60 feet, speed sixteen knots, capacity 1,050 passengers.

The directors of the Richelieu and Ontario Navigation Company have appointed a new official, to be known as inspector of stewards. H. Bonchard, who has been in the employment of the company for 17 years, has received the appointment, with headquarters at Montreal.

J. A. Mara, late member of parliament for Yale and Kootenay, is building a river steamer at Vancouver for the Yukon traffic. She is said to be the largest boat that will be employed on the rivers up North, being 520 feet long, 32 feet beam, 5½ feet depth of hold, and will cost in the neighborhood of $25,000.

The Canadian General Electric Co. has a contract for supplying three direct-connected units for the C.P.R. steamers which are to go on the Stikine route. These units will consist of a 4-kilowatt, 70-light incandescent dynamo, direct-connected to a vertical high-speed engine, running at 606 revolutions per minute.

W. Bell Dawson, engineer in charge of Tidal Survey, has this year issued, in neat pamphlet form, Tide Tables for Charlottetown, Pictou and St. Paul Island, C.B., for 1898, with Tidal Differences for Northumberland Strait, and for the open Gulf shore, from Miramichi along the north coast of Prince Edward Island.

The Canadian General Electric Co. is installing a Direct Connected Lighting unit on board the C.P.R. steamship Athabasca, consisting of a 500-light incandescent dynamo, direct connected to a 50 h.p. high speed "Ideal" engine. This unit, which is very compact, occupies a floor space of less than 6 ft. x 9 ft. The dynamo is of the latest steel frame multipolar type, with ventilated armature. A marble switchboard, on which are mounted a standard equipment of instruments, is also part of the new equipment, which when finished will be the most complete on any of the steamers now running on the upper lakes.

Capt. Crawford will again this year be Commodore of the Hamilton Steamboat Company's fleet. He will sail the Macassa in the spring and fall and the Modjeska during the busy season. Capt. Maddicks will be in command of the Macassa while Capt. Crawford is on the Modjeska.

The total number of casualties to British and Canadian sea-going vessels in Canadian waters, and to Canadian sea-going vessels in waters other than those of Canada during the year, as stated in the report to Parliament, of the Dept. of Marine, was two hundred and thirteen, representing a tonnage of 80,317 tons register, and the amount of loss, both partial and total, to vessels and cargoes, as far as ascertained, was $718,293. The number of casualties to inland vessels was twenty-seven, tonnage, 5,726; loss, $48,350. The number of lives reported lost in connection with these casualties was thirty-four.

The following candidates, recently examined by W. L. Waring, St. John, N.B., have passed and will be granted marine certificates: Geo. H. Waring, jr., of St. John, second engineer of Prince Rupert, chief engineer's certificate, valid in Great Britain; Fred. John Lewis, of St. John, second-class certificate, valid in Great Britain; Charles Helman Hanson, of Chatham, third-class certificate; Geo. Frederick McRoberts, of St. Andrews, fourth-class certificate; George Herbert Burpee, Sheffield, Sunbury County, fourth-class certificate.

The Manhattan Steamship Company was incorporated Jan., 1898, with a capital of $1,000,000, with the following directors: J. J. Hillman, Philadelphia, president; Jos. D. Huggins, New York, vice-president; N. L. Newcomb, New York, general mgr.; H. E. Alexander, Wm. F. Weiss, Thos. W. Buck, Roland F. Hill, Tunis G. Bergen, New York; Isaac C. Ogden, Orange, N.J.; Beverley S. Reed, Boston; C. Everett Evans, Taunton, Mass. The offices of the company are at 11 Broadway, New York. Contracts have been given for the construction of three steel twin screw passenger and freight steamers. The dimensions of these steamers are 250 feet long by 45 feet beam. Each of these steamers contains two engines, 22 x 36 x 55 x 28 inch stroke; six boilers, 11 feet 6 inches in diameter by 12 feet 6 inches long, giving a sea speed of 17 knots per hour. These steamers are of the most modern construction, with large space devoted to cold storage. The company will operate a steamship service between New York, Maine and the maritime provinces. Pier No. 1, North River, New York, has been leased at a rental of $35,000 a year for a period of ten years.

Considerable discussion is going on in marine circles in St. John, N.B., on the subject of marine engineers' permits. The regularly qualified engineers are not satisfied with the present system of granting such permits, and claim that there are many inconsistencies in the laws with regard to granting papers to men to make them marine engineers and in the rulings of the men who are in power to grant the papers. The engineers who study the laws, say that a fourth class engineer, who is compelled to have certain machine-shop experience, and also experience in the engineering of a steamboat, is not permitted to take charge of the machinery of any passenger boat, and the man who holds the permit has not to have all these qualifications and can run any passenger boat of nine-horse power. The act provides that a temporary certificate may be granted and be in force for a term not exceeding one year to an applicant "sufficiently qualified by his knowledge of steamboat machinery, and his experience as engineer on a steamboat, authorizing him to act as an engineer of a steamboat carrying passengers, having an engine of not more than four nominal horse power if the engine is a single cylinder engine, or nine nominal horse power if the engine is of the compound type.

Everything in the marine line is rushing at Gravenhurst, Ont., "We had the launch of a new steamer built last winter for Homer & Co., of this town," writes a correspondent. "She is 65 feet long, 14 feet beam, 6 foot hold. She is built all of oak timber, and calculates for a passenger steamer will carry 130 passengers. Her speed is 12 miles an hour. She was built by Davis & Sons, Kingston. The same firm have a contract to enlarge the steamer "Kenozha," for the Muskoka Nav. Co. They are adding 18 feet to her length, making her 126 feet long. There will be new cabins, 56 feet long, built on the promenade deck, besides new pilot house, and captain rooms on the hurricane deck. Her rebuilding will cost $3,000, and is to be ready for work by June first."

Railway Matters.

The Quebec Central Railway is making extensive additions and improvements at the car shops in Newington. A new engine house, with a capacity of ten engines, has been erected.

The Grand Trunk will lay 120 miles of new track this summer between Niagara Falls, Sarnia and Windsor. The new rails will weigh 80 pounds to the yard; that which is down at present weighs from 56 to 66 pounds.

The managers of the Ottawa & Parry Sound R. R. have purchased sixteen new mogul engines in anticipation of a great increase in the grain business. They are ten-wheelers, and weigh 156,000 pounds each, without the tender or water in the boilers.

The Grand Trunk Railway Company will move the head offices of two branches of the construction work to Toronto. General Roadmaster Ferguson will be established here with his staff, and offices are also being prepared for the superintendent of bridges.

Both the G.T.R. and C.P.R. are introducing a new code of lamp signals to use on their freight trains. In addition to the usual tail lamps there will be an extra large one placed on the top of the conductor's van, and will be known as the copula lamp. This lamp will be an extra safe-guard against rear accidents. The engineer will also be in better communication with the end of the train.

Sir William Van Horne, at the annual meeting of the C.P.R. shareholders, remarked, in connection with the double-tracking of the Montreal-Toronto line, that it is ultimately intended to double track from Port Arthur to Winnipeg, and from Montreal to Farnham, and steps had already been taken in that direction, but the Montreal-Toronto section was regarded as the most urgent.

The following new appointments on the Canada Atlantic Railway went into effect recently. Mr. C. J. Smith is now general traffic manager; Mr. J. E. Walsh has been appointed assistant general passenger agent; Mr. W. P. Hinton has been appointed assistant general freight agent. These officers will have their headquarters at Ottawa, where the general offices of this company are located. Mr. M. A. Overend has been appointed foreign freight agent, with headquarters at 115 Board of Trade Building, Montreal.

Premier Greenway's Manitoba Ry. scheme includes 80 miles south-east from Winnipeg towards Lake of the Woods, upon which a guarantee of $8,000 per mile is given, controls rates secured as on the Dauphin railway, also large reductions on cordwood and sawlogs, which, it is believed, will bring the mill to Winnipeg. Next year arrangements will be made to connect the line with the Rainy River railway, and thus secure the road to Lake Superior, with a ten-cent rate scheme; also includes extending the Dauphin railway 140 miles north to the Saskatchewan River, through the fertile Swan River valley; also on a guarantee of $8,000 per mile, the government being secured by a first mortgage on the road. This will be half way to Hudson's Bay.

In the case of P. Hannaford v. the G.T.R., the plaintiff claims a year's salary ($6,000), in lieu of notice, and claims that his discharge was without cause and illegal, putting in evidence a letter from Sir Charles Rivers-Wilson, in which it was stated that nothing but absolute necessity caused the directors to dispense with Mr. Hannaford's "valuable" services. The company, on the contrary, claim that Mr. Hannaford had used his position for purposes other than the interests of the company; that he had employed servants of the company to do work for himself; that he had promoted his son without getting the approval of the general manager of the company to the promotion, and that, in any case, he knew of and approved an agreement signed by the employes of the road to accept a month's warning at any time. Strong evidence was given by several employees that they had done work for Mr. Hannaford on his private residence, both in time and with materials paid for by the company.

Word has been received at Kincardine, Ont., of the death of L. B. Hamlin, C.E., formerly, it is said, resident of that town. Mr. Hamlin was county engineer of Bruce for some years. He was engaged on the Government service in the Yukon country, and was frozen to death in the Klondyke.

Personal.

W. J. Harkom, Montreal, is appointed assistant to the mechanical superintendent of the C.P.R.

The death of Captain Campbell occurred on the S.S. "Lake Ontario" on Saturday, April 2.

Geo. Booth, Toronto, was elected treasurer of the Canadian Manufacturers' Association at the recent annual meeting.

D. J. Macdonald, B.C. Provincial Mine Inspector, resigned his position on April 10. He has taken a position with a mining company and will reside in Rossland.

James Warren, C.E., Walkerton, Ont., has been appointed town engineer for Waterloo, Ont. The town is without a map, and the first thing Mr. Warren will have to do is to make one.

The Chatham city council has appointed Charles Topp, C.E., of Bracebridge, city engineer. The salary will be $1,000, and the present waterworks engineer's services will be dispensed with, it is said

At London, Ont., April 11th, Miss Mary Rolston was married to Samuel Break, general manager of the London Electrical Construction Company, and formerly superintendent of the London Street Railway.

J. A. Sheedy, of the Illinois Bridge Works, Chicago, Ill., has been appointed master of bridges and buildings on the Grand Trunk Railway system, in place of Will am Crawford, of London, Ont., resigned.

T. E. McLelan, manager of the Berlin and Waterloo Street Railway, has resigned his position to go to the Klondyke. He will be succeeded by Hedley H. Hilborn, of Montreal, who has been in the service of the Montreal Street Railway.

H. B. Spencer has been appointed superintendent of the Eastern division of the C.P.R. and the Montreal-Ottawa line, with headquarters at Ottawa. J. E. A. Robillard, the former superintendent, will have charge of the Labelle and St. Jerome branch of the C.P.R.

P. A. Dickson, aged 40, died at Brantford, April 24th. He was for a number of years electrician for the Brantford Electric Power Company, leaving there last summer for British Columbia, where he contracted a severe cold, which resulted in his death.

Mons. Ephrem Valiquet, who has just been elected president of L'Association De Secours Mutuels des Ingenieurs Mecaniciens, was presented by W. Rutherford & Sons with a handsome silver jug as a token of respect on the occasion of his leaving their employ to become foreman for Lymburner & Mathews, of Montreal.

William Wilson, engineer of the S.S. "Alert," died suddenly a short time ago, he having, up to the hour of his death, been in perfect health. He was a native of Glasgow, Scotland, and came to St. John's, Nfld., 37 years ago, as engineer to Baine Johnstone & Co ; since then he has been with Bowring Bros., in the Tug Co., and for the past 11 years an employee of Job Bros.

Prof. Hugh L. Callendar, F.R.S., of McGill University, has been appointed to the Quain professorship of physics at University College, London, vacated by the resignation of Professor Carey-Foster. The friends of Professor Callendar cannot but be pleased at his appointment to what is considered a leading professorship in England, but there is not so much rejoicing at McGill, where his talents will be greatly missed. When accepting Prof. Callendar's resignation the McGill Faculties of Arts and Applied Science unanimously passed a resolution of regret in which they expressed their appreciation of his great merit and ability.

John Watson, the well-known stationary engineer, died recently at his home in Montreal. Mr. Watson was born in Edinburgh, Scotland, seventy-eight years ago, and came to Montreal when about twenty-six years of age. He was for a number of years employed by the Grand Trunk Railway, and had the distinction of making one of the party that accompanied the first engine run over the line to Lachine. Afterwards he went into business for himself as a machinist on Chenneville street, and later was in partnership with his brother, the late Thomas Watson. When the new post-office was built he accepted the position of engineer there, where he was up till about four years ago.

The harbor master of Montreal, Captain Thos. Howard, who died recently at his home in that city, was born at Shinroan, Queen's County, Ireland, on September 15, 1826, and came to Canada in 1842. For a time after his arrival he was in the employ of the late Hon. John Hamilton, and later on entered the service of the Richelieu & Ontario Navigation Company. For some years he commanded the "Banshee," "St. Lawrence," and other vessels of the company plying between Montreal and Western ports, and was subsequently appointed manager of the Ontario division of the company. In March, 1881, he was appointed harbor master at Montreal, a position which he held until the day of his death.

Prof. C. A. Carus-Wilson has announced his intention of resigning the chair of Electrical Engineering at McGill University on September 1. He came to Montreal in 1890, having been previously on the staff of the Royal College of Engineering, Cooper's Hill, England. His resignation will be a great loss to McGill College. His future permanent address will be "Hanover Lodge, Kensington Park, London W., England." During May, Prof. Carus-Wilson will give the Cantor lectures on electric locomotives at the Society of Arts, London, and throughout the summer he proposes to devote special attention to electric railways, a subject of great and increasing importance in England now. The volume on electro-dynamics which he has written for Messrs. Longmans, Green & Co. (London and New York), will be published at once.

Chauncey M. Depew retired from the presidency of the New York Central on April 20th and was succeeded by S. R. Callaway. Mr. Callaway is a Canadian, entering the office of Mr. Hickson at Montreal in 1863, when 13 years of age. In 1865 he went as secretary to Gilman Cheney, manager of the Canadian Express Company, and left there in 1869 to enter the service of the Great Western Railway under W. Wallace, the superintendent at London, and subsequently private secretary to W. K. Muir at Hamilton. Mr. Callaway retired from the Great Western to enter the service of the Detroit and Milwaukee, of which road he was superintendent from 1875 to 1878. Upon the absorption of the D. & M. Railway by the Great Western Mr. Callaway was appointed general superintendent of the Detroit and Bay City Railway, and in 1880 general manager of the Chicago and Grand Trunk and president of the Western Indiana railways. In 1884 Mr. Callaway accepted the position of vice-president and general manager of the Union Pacific Railway and the allied lines of nearly 6,000 miles. In 1887 he was elected president of the Toledo, St. Louis and Kansas City Railway, and since then he left that road to accept the presidency of the Lake Shore and Michigan Southern Railway.

FIRES OF THE MONTH.

April 1st.—The Sine Creamery, Sine P.O., Ont., destroyed.——April 2nd.—Geo. H. Hees, Sons & Co., window shade factory, Davenport Road, Toronto. Loss, $40,000, being rebuilt.——April 8th.—G. W. Green's wood-working factory, Ashburnham, Ont. Loss, $8,000 ; insurance, $4,500.——April 8th.—Lebel & Wilson's Lead Works, London, Ont. Loss, $4,000.——April 11th.—Chadwick Bros., Hamilton, metal spinning shop. Damages about $200.——April 13th.—F. Routhier & Sons, foundry, Vankleek Hill, Ont. Loss, $3,000 ; insurance, $1,000.——April 13th.—Small saw mill, Newbury Junction, N.B. (Jas. Carr, Woodstock, N B., proprietor). Loss, $2,000.——April 19th.—Doan's tannery, Clinton, fire starting in the boiler room. Total loss.——April 19th.—Ore house at the Payne mine, Nelson, B.C. Loss, $10,000.——April 19th.—Gaw's planing mill, Place D'Armes, Kingston, Ont. Loss, $12,000 ; insurance, $5,000.——April 23rd.—The cupola of Wortman & Ward's foundry, London, Ont. Damages, $500. ——April 30th.—The Rathbun Co.'s terra cotta works, at Deseronto, Ont., plant destroyed. Loss about $100,000 ; partially iusured.——May 1st.—Jas. McLatchie's machine shop, Cardinal, Ont Loss about $5,000.

IMPULSE WATER WHEELS.*

By J. T. Farmer, Ma.E.

The development of power by means of impulse water wheels, has been receiving considerable attention during the past ten years. Water power is to be met with under varying conditions and in various surroundings; and the means best adapted for the utilization of the power vary with those conditions and surroundings.

Among the means devised by man at different times before the advent of the impulse wheel for utilizing the water power that was going to waste around him, one has easily taken the foremost place, and, indeed, has, by a process of the survival of the fittest, practically ousted all other methods from a position of being worthy of serious consideration. The turbine has at the present day almost entirely taken the place of the earlier devices in use, which have either been consigned to museums as curiosities or are regarded as picturesque additions to the landscape.

The impulse water wheel probably differs as much from the various forms of turbine in construction and in action as the turbine does from an overshot or breast water wheel. The previous statement with regard to the turbine must therefore be further modified so far as it is found that the impulse motor is finding favor with those who utilize water power.

*From a Paper read before the Canadian Society of Civil Engineers.

It has been said that "countless wealth is being squandered in all the torrents and water courses of the world." But it might be added that unless the proper means are taken for its utilization, wealth of energy avails little more to man than that of the tides of Jupiter.

It seems at first sight a very simple matter to place a wheel in position to take up the energy of water; but in practice that arrangement is generally found to involve more or less costly construction in the way of dams, basins, canals, flumes and even tunnels. This is particularly the case where the use of turbines is contemplated, and this consideration is frequently sufficient to annihilate the expediency of thus attempting to utilize a known and otherwise available source of power.

These adverse conditions are forcibly illustrated in the mountainous districts of the North American Continent. Water power is there in abundance, but it is that of mountain torrents: as a rule inconsiderable in volume of water, but, on account of the configuration of the country, affording large heads. The latter circumstance makes any constructive work very costly, and in most instances would put the use of an ordinary turbine out of the question.

It was from such causes that the Western States became the birthplace of that system of water power of which the essential feature is an impulse water wheel. The simplification made possible in this system is that of the substitution of a pipe and nozzle of insignificant dimensions for the massive head race and wheel pit associated with the use of a turbine.

The first impulse wheels brought into use were of the very crudest description; with the increasing use of the system, however, came the development which attends every invention which has a large field of usefulness open to it. The impulse wheel of the present day ranks as fairly efficient among the various means of utilizing natural energy.

At this stage it becomes a question to what extent it may be desirable to employ the impulse wheel outside the conditions under which it first sprang into existence. This problem is specially interesting in a country where there is an abundance of water power, and at a time when the utilization of water power is assuming the place of one of the most important engineering questions of the day. The object of this paper is to record the results of some experimental research on this subject, and also to discuss the question by the light of those results and from other considerations.

The history of the development of the impulse water wheel may advantageously be sketched briefly. The first wheels of this class were simply provided with flat projections on the rim of the wheel, and the jet was arranged to impinge normally on these flat surfaces. This was what was known as the hurdy-gurdy. It can easily be shown from theoretical considerations that the ideal efficiency of such a wheel is 50 per cent., but it is probable that most of those in use did not give a greater efficiency than from 20 to 30 per cent.

The first notable improvement was that of substituting hollow cups for the flat vanes, so that the jet struck the interior part of the cup and was deflected back again until it left the vane, traveling, with respect to the vane, in almost the opposite direction to that in which it was traveling before impact. This formation at once largely increased the efficiency, but in practice the efficiency was still far from what it theoretically might be.

The next modification was that of so curving the surface of the cup that the jet might follow the surface with very little deviation at the first point of contact. Thus some wheels are formed with a conical projection in the interior of the cup at the point where the jet strikes the surface, so that the water on striking may begin to pass along the generating lines of the cove, and may gradually be deflected further to follow the curved sides of the interior of the vane. The more common construction is to place a wedge-shaped projection across the interior of the cup or vane. This modification was introduced about 1880. The function of the wedge is two-fold.

(1) To prevent the heaping of dead water upon the vane during its passage through the arc of action, or the part of its path in which the vane receives the jet of water. (2) To give the diverted streams a direction of motion which will finally carry them clear of the wheel.

In a bucket unprovided with any conical or wedge-shaped projection, there is no sudden angular deflection of the water. Some of the water is heaped upon the flat surface upon which the jet is impinging, thereby forming a curved surface over which the following water is deflected. With a stationary vane on which the stream is continuously playing, the loss of force due to this cause is very slight. When, however, the impact is taking place intermittently on a moving vane, the dead water is discharged after very inefficient action at the end of every short period of action, and the total loss in effective work may be considerable. This loss is reduced by placing a solid projection in the bucket, which takes the place of that formed by the water and leaves all the water free to be deflected in the most efficient manner. As regards the second function of the wedge, it is well known that when a stream of water strikes normally upon a surface, it is deflected equally in all directions. This is illustrated in the wheel bucket. The same action takes place when the stream strikes centrally upon the apex of a cone. This is undesirable in the case of the vane of a water wheel, as the water which is deflected towards the centre of the wheel gets into position to strike the back of the following vane, thus opposing the useful effect of the action. Then the jet strikes a wedge, it is cut into two portions, which are deflected away from one another in a plane perpendicular to the cutting edge of the wedge. In a wheel this motion causes the water to be discharged at each side of the wheel where it is free from all liability to interfere with any following parts of the wheel.

Numerous modifications of the form of the curved surfaces of the buckets have been brought out at different times by inventors with a view of modifying the passage of the water over the vane in some particular, but it is not necessary to describe them more particularly.

Of the impulse wheels in use at the present day the best known is probably the Pelton water wheel. These wheels are made in sizes varying from 6 in. to 6 ft. in diameter, according to the head of water available, and the velocity required. These wheels have been applied under heads ranging up to 1,700 feet, and, as has been said, there is no doubt that under such conditions the highest efficiency is realized. On the other hand, there are said to be instances in which Pelton wheels are running with good results under heads of from 50 to 75 feet.

The writer recently made a series of tests on a small wheel of this class, catalogued as the Pelton Motor No. 3. This wheel is approximately 18 in. in diameter, and the weight of the whole machine is given as 320 pounds.

The tests were made in the hydraulic laboratory of McGill University, and a brief description of the methods employed will be given. It was impossible to make tests with heads as high as some of those under which these motors run. The maximum head employed was that afforded by the city supply from the high-level reservoir, which gives a pressure of 125 lbs. per square in. in the laboratory, equivalent to a head of 290 feet. Lower pressures were also obtained by throttling the supply from the same source. These trials will give an idea of what may be expected of this type of motor when used under ordinary heads of from 100 to 300 feet. In many districts these are as large heads as are commonly met with. Also, where it is proposed to take power from a water-works system, the pressure under which water is supplied would rarely exceed 125 lbs. per square inch. In the present series of trials the wheel tested was small compared with many in use: the effective work done did not in any case exceed 7 horse-power. There is no doubt that with a machine designed on a larger scale, as with larger heads, the efficiency would show some increase over the values found in the present case. The results obtained in these experiments are offered as bearing directly on the question of the utilization of this system for small amounts of power under the conditions usually met with in districts outside those referred to as abounding in very high falls of water. With reason and judgment, the general conclusions arrived at by the consideration of these results may be extended to cases where the machinery and the generation of power is on a larger scale.

For the purposes of trial the wheel was set up as received from the makers, and the auxiliary apparatus was fitted in accordance with their instructions. The water, after passing through the valve which was used to regulate the pressure, was led along a length of 2½-inch pipe straight for 8 or 10 feet before reaching the nozzle. A Bourdon gauge was fitted on the supply-pipe less than one foot from the mouth of the nozzle-tip. This gauge was arranged on a pressure-chamber, enveloping the pipe and communicating with the interior through a series of small holes. Before being used the gauge was calibrated by means of a gauge tester. In the experiments the

pressure in the pipe of course varied slightly. The pressure was read at intervals of one or two minutes, and the mean value during the whole trial was accepted as the pressure under which the flow took place. The extreme variation of the pressure was about one pound per square inch.

Three different sized nozzle tips were supplied with the wheel. These nozzles tapered gradually on the inside from the diameter of the supply pipe to that of the actual orifice. The outlet diameters were : .5277 in., .6307 in., .7532 in. Sets of trials were made, using the largest and smallest of these nozzle tips, the largest giving the more satisfactory results. The water was discharged from the motor into a flume beneath, whence it ran into measuring tanks, and all the water used was thus actually measured. For the purposes of these trials two tanks were used, each of the capacity of 1,000 gallons; these had both been previously calibrated. The power given by the wheel was estimated by means of an absorption brake and a revolution counter. The shaft was provided with an 18-in. diameter brake wheel of special design, and the power was taken off this. In the earlier trials the brake consisted of one or more cords embracing a suitable arc of the periphery of the brake wheel, and having spring balances attached to the tight and slack ends to indicate the corresponding tensions in the cord. As the power varied slightly all the time, both readings were taken at intervals of one or two minutes, and the means used in calculating the final result of the trial. Later a direct-reading, self-adjusting brake, designed by Mr. Withycombe, was substituted for the cords and spring balances with very satisfactory results.

An ordinary revolution counter was used, but arranged to be thrown in and out of engagement with the shaft at the beginning and end of each trial. The necessary readings could thus be made at leisure, ensuring greater accuracy.

In addition to the revolution counter a tachometer was connected to the shaft. This served as a guide when adjusting the load on the brake wheel previous to a trial to give a desired speed of running. It also served to indicate any considerable departure from the intended speed which might take place during a trial, and which would vitiate the accuracy of the calculated results.

Before passing to the examination of the experimental results of the trials, it may be well to make a brief theoretical analysis of the subject. The elementary theory of an impulse wheel is very simple—so simple, indeed, that no attempt seems to have been made to consider to what extent known and observable phenomena may modify theoretical calculations; but rather the elementary theoretical result is generally taken as the last word which can be said on the subject from a theoretical point of view.

In the following investigation the efficiency is deduced from a consideration of the circumstances, as far as they can be mathematically expressed, under which the mechanical action takes place.

In the elementary theory of the impulse water wheel the assumptions generally made are substantially as follows:

1. That the jet has the theoretical velocity due to the available head of water. 2. That the jet strikes the vane centrally and tangentially to the wheel. 3. That the jet passes over the surface of the vane without any loss of relative velocity. 4. That the vane is so formed as to turn the stream through an angle of 180 deg. completely back on itself.

FIRES AND FIRE-PROOF CONSTRUCTION.

Editor CANADIAN ENGINEER:

SIR,—I have, as requested, looked through the pamphlet you were kind enough to send me, on the Paris Charity Bazar Fire, by Arch. E. O. Sachs, author of Fires and Public Entertainments, Modern Opera Houses and Theatres, etc.

This paper was prepared by the author for the Architectural Association, and read at its second ordinary meeting, session of 1897 98, Hampden W. Pratt, F.R.I.B.A., president, in the chair, and was commented on after its reading by Richard Roberts, L.C.C., vice-chairman Theatres Committee, London County Council; Sid. Gamble, A M.-Inst. C.E., F.S.I., second officer Metropolitan Fire Brigade; Major Fox, chief officer Salvage Corps; Thomas Blashill, F.R.I., B.A., F.S.I., superintending architect London Common Council; Capt. Dyson, chief officer Windsor Fire Brigade; William Archer; Henry Lovegrove, A.R.I.B.A., F.S.I., district surveyor for Shoreditch; Max Clarke, A.R.I.B.A. It has been published by the British Fire Prevention Committee, C. and E. Layton, publishers, Farringdon street, London.

I find the consensus of opinion in this case to be that while the fire was caused by an explosion of some of the essential oils used in the exhibition of the Kinemetographic views, the conflagration and the destruction of the building were disastrously hastened by the fact of the roof drapery having been immediately ignited by the explosion, the flames in an instant running along the whole building, some 300 feet in length by about 40 in breadth, setting fire to the woodwork and flimsy paper and other decorations of the interior, which, falling from above directly onto the heads of the lightly-clad ladies in attendance, set fire to their hair, their head gear and dresses, thus causing the simultaneous and almost instantaneous death of 124 persons on whose heads and shoulders at the same time the broken glass from the continuous skylight was falling, cutting into their flesh and inflicting painful wounds and bruises. Still, quick as the destructive element was in bringing about this most terrible result, the committee is of opinion that had the several emergency doors which were barred and bolted at the time, been opened as they should have been by persons told off in advance to do the duty, not one half of the fatalities would have occurred, maybe not one tenth of them, as the victims issuing into the open could have been cared for by outsiders, who would have seen to the safety of all of them and have probably reduced the casualties in most cases to more or less severe injuries to be got over in course of time.

Mr. Sachs recalled the Vienna Ring Theatre fire of 1881, with its 450 fatalities; the Opera Comique fire in 1887, with a death roll of 115, and other great catastrophes; the Exeter theatre fire of 1887, where 160 lives were lost, followed by a serious fire at Oporto with the loss of another 100 lives. He might also have remembered the Bordeaux theatre fire, the Santiago church horror, where 2,000 souls were hurled into eternity, and the Brooklyn theatre fire of 1872 (I believe), where 276 more lives were sacrificed. Mr. Sachs comments upon the fact of how soon these disasters fade from memory, most of them, he says, having been forgotten within from three to seven days of their occurrence.

The London Committee calls on Parliament, or intends doing so, to interfere and force municipalities to attend to the safety of the public by refusing to sanction the erection of such flimsy and dangerous structures and decorations, and I am certainly at one with the committee in refusing to understand how it is to be considered as interfering with the individual liberty and action to enact such laws, any more than legislating on compulsory vaccination and other hygienic safeguards to the public health; for, as above set forth, there is no doubt that, had not the incriminating ceiling cloths been there, or one of asbestos or other inflammable material, and parties at hand to open the seven doors of the building aggregating some 40 feet in width, the Charity Bazar horror would not have been to any extent as serious as it has proved to be.

TENDERS ARE ASKED FOR

Addressed to S J. CARTER, Secretary-Treasurer Andover (N.B.) Water Commissioners, for the

Excavation and laying of 2½ miles of 6-inch Water Main

AND

Construction of a Dam 80 feet long and 10 feet high

Plans and Specifications to be seen at the office of the Commissioners.

C. L. B. MILES, Engineer,
ANDOVER, N. B.

April 27th, 1898.

For Sale Cheap

A New 100 Kilowatt 125 Volt Multipolar, Direct Current Dynamo

Latest steel frame type, with iron clad armature.

A most complete set of Station Attachments. Suitable for Incandescent Lighting, with a capacity of 2,000 16-candle power lamps, or for power or electro-chemical purposes; has never been used only for a test.

For particulars apply to E. H. HILBORN, 74 Brunswick Avenue, Toronto, or to JOHN TOLMIE, Kincardine.

The Ontario People's Salt and Soda Company, Limited

MUNICIPAL OWNERSHIP.

BY RODERICK J. PARKE.

The discussion of this interesting and important question has during the past few years called forth arguments so varied and so numerous that to the non-technical, although directly interested, citizen, the matter has assumed of late a more or less chaotic condition, and a satisfactory solution seems to be no nearer achievement than formerly. For the benefit of those who have been unable to follow the arguments through the columns of the various technical journals, the writer will endeavor to present as briefly and clearly as he can the principal considerations influencing the agitations for and against, and the actual control of, municipal industrial services, and more particularly that branch of the services which embraces the supplying of electrical current for street lighting and private consumers' purposes. This article is not intended to advocate municipal in preference to private ownership, or vice versa, but merely to place before the reader those facts which will have to be carefully considered before an intelligent, unprejudiced conclusion can be arrived at respecting either form of ownership, to the possible exclusion of the other, in those localities in which the question may arise.

To present the subject in a proper light, it is necessary to first ask and answer this question, namely, "What are the principal motives prompting the increasing agitations in favor of municipal ownership? The answer is found to be: (1) The prospect of reducing the cost to taxpayers and private consumers for street and private lighting services. Other motives in the order of their importances are: (2) That the municipality should avail itself of the profits of commercial services, for obvious reasons; (3) Dissatisfaction with the service as rendered by the local company; (4) Local political considerations, and less frequently, purely personal motives among some certain citizens.

Granting, then, that the first-mentioned motive is the prime one influencing the agitation, the question resolves itself not as to who should own the source of supply, but as to whether a cheaper and more efficient public and private service cannot be obtained, and if so, at what proportionate reduction on present cost. Present results show beyond the possibility of a doubt that, giving the same conditions as formerly, in reference to population, cost of fuel and other local conditions, electrical current can be profitably supplied at in some cases a very considerable reduction to the consumer, if modern methods and apparatus be adopted by the central station manager. Competent authorities emphatically point to the fact that if it can be shown that private enterprise can supply municipal industrial services as cheaply and economically as through municipal ownership, very few will be disposed to question the policy of permitting private ownership to continue, providing, of course, that the private corporation will accede to the popular demand. Unfortunately, however, the local company, secure in the monopoly it holds, more often exhibits an utter disregard for the rights of the public, hence the movement for supplying a remedy through municipal ownership. Other reasons for this disregard are lack of enterprise and ability on the part of those responsible for the inefficient and unprofitable condition of the system. In villages and the smaller towns, however, where the demand is necessarily confined within certain limits, the cost of manufacturing is proportionately higher, even with the most efficient machinery, than is the case in the larger towns and cities, hence the public should exercise careful discretion when attempting to compare prices existing in any two localities having a marked difference in population. The individual commercial conditions should also be carefully compared.

The public has every right to demand in return for the privileges accorded to the private corporation in the locality, that the service shall be rendered in the best manner known to be commercially practicable, and at the lowest reasonably profitable prices. Failing in this, the owners of the system can have no cause for complaint in the event of the municipality taking the matter into its own hands, as already illustrated in a number of cases. The question now comes up, whether the company is giving a sufficiently good service to the municipality and at the lowest consistent prices. On this question a great many differences of opinion are found to exist among those directly interested, the only apparent method of arriving at an exact estimate being to have the methods and operations of the system carefully investigated by a board of competent and thoroughly disinterested electrical experts appointed one from each side, and a third chosen mutually by the first two. In this way, assuming the rigid integrity of the experts, the municipality and the company cannot fail

in having their respective interests protected fully and impartially, and a mutually profitable and agreeable understanding promoted. If the results of the investigation show that improvement is warranted and feasible, then let such improvement be made. There should be no reason why central stations should be behind the times, or be commercial failures any more than other industrial enterprises, and if through any avoidable mistakes or errors the owners persist in forcing an unsatisfactory and needlessly expensive service on the community, it is plainly the duty of the citizens of that community to endeavor to set matters on a better basis. And conversely, if the company honestly will make every effort to do its work well and in good faith, it certainly has every right to expect and demand good faith from the municipality.

In the majority of instances of disagreements existing between municipal authorities and the central station owners, the trouble is due in a great measure to misconceptions and exaggerated ideas arising through technical ignorance on the part of the former, and often a mutual distrust of the other's intentions and motives, on the part of both, with consequently disastrous results to the vested interests of the owners when the power of a majority is taken advantage of by the municipality. To instruct the authorities sufficiently to enable them to conduct an impartial and competent inquiry into the workings and methods in vogue in the local central station is out of the question, while to expect them to blindly accept the arguments and statements of the owners is in the majority of instances equally inadmissible. The establishment of a provincial board of industrial commissioners, capable of technically inquiring into and competently advising municipalities on such matters, would seem to be the most advantageous method for all concerned, or, in the event of there being insufficient necessity for the permanent existence of such a board, a temporary one could be drawn from among the ranks of those disinterested members of the electrical profession making a specialty of works of this nature. The central station owners where they have not legally forfeited the right to expect leniency and consideration at the hands of the municipality should certainly have due regard shown their interests as far as can be consistently done, in view of the fact that at the time when the station was established, assuming this to have taken place not less than five years ago, comparatively much inferior and more inefficient methods and apparatus were taken advantage of as being the best then known. In those instances where during the profitable operation of the central station for a period of several years, the owners have shown culpable lack of enterprise in failing to improve the particular system where such would be necessary in order to assure the supplying of an increasingly efficient and up-to-date service at proportionately lower prices, the justice of compelling the municipality to repay to the owners their original outlay for the equipment, is open to serious question, particularly if that equipment be out of date, insufficient, and in a badly depreciated condition. And even though the owners be willing to accept a considerably reduced price for their equipment, the fact must be borne in mind that in order to place such on a modern and more efficient basis the only alternative left is that accepted by the wide-awake manager, namely, to discard the old and install more capacious and efficient machinery and to practically reconstruct the system. Where any part or portion of the old equipment can be advantageously continued in use as a part of the new system, a reasonable allowance should be made on such to the owners, and that part or portion adopted. The tendency, however, seems to be in the majority of cases to ignore the owners as far as possible, and to purchase an entirely new outfit. Whether this policy be a judicious one depends altogether on the nature and quality of the local system to be supplanted, and will be discussed in a future article. It may be remarked just here, however, that a great deal of the machinery and apparatus installed a few years ago would be dear at any price if adopted in a modern central station, where the latest types and highest quality of equipment are necessary to meet the conditions under which the station should be operated. The enterprising manager, alive to his own interests, has already perceived the necessity of operating his equipment under the most economical methods, and that in order to do this the many needless and avoidable wastes of power in process of translating the energy of the coal pile into light and motive power due to poorly designed and inefficient devices must be stopped, as far as the latest developments of the science have shown to be practicable. In consequence of this the said devices have been disposed of to the dealer in second-hand apparatus, or sent to the scrap heap, and the more efficient apparatus installed. If, then, the practical manager finds it to his interests to get rid of his out-of-date machinery, is there any valid excuse for compelling the municipality to cover the losses incurred through the incompetent manager's failure, when it is found necessary or advisable to establish an improved system on its own account, and where in any event the old system would have to be replaced by a new one ?

An article of much interest, bearing on up-to-date management of public lighting plants, appears in the editorial columns of the Electrical Engineer of May 26th, 1898, and is well worth reproduction, in view of the fact that this journal actively opposes municipal ownership. This article, entitled "An Object Lesson for Municipal Plant Advocates," says :—

"It is now about ten years ago that the then Mayor Grant of New York ordered the electric light poles of this city to be hacked down with axes and the wire carted to the city junk yard. This policy of violence was the first step toward the placing of the wires underground, and although no one would now go back to overhead wires, the method adopted for bringing about the result will always be considered arbitrary and uncalled for. In striking contrast with the ex-mayor's procedure is the painstaking and intelligent manner in which the officials of Providence, R.I., have gone about adjusting questions of this kind with the local lighting contractors, the Narraganset Electric Lighting Company. The latter company has an exclusive franchise for electric lighting in the city, but instead of abusing its privilege, has steadily increased its hold on the public confidence by its policy of fair dealing emphasized by a steady reduction in rates. Recently a committee of the city council was appointed to report upon the placing of high tension wires underground, and the committee's report now lies before us. Before formulating its report the committee undertook a trip of inspection of underground work in various cities, and that it was not a junket is evident from the fact that the committee traveled at its own expense. The proposition which it sanctions for adoption by the city council is substantially that submitted by the electric lighting company. This contract provides for the gradual removal within three years of all the overhead wires and their placing in underground conduits within what is termed the first building district of the city. At the same time the lighting company agrees to a gradual reduction of the price for lighting from 35 cents to 30 cents, to take effect in 1903, for 2,000

c.p. arc lights burning 4,000 hours per year. Considering the expense which the burying of the wires will entail, the rate just quoted will be conceded to be very low—one indeed that will require the highest economy in all departments of station work. But President Perry of the Narraganset Co. has always had a reputation for wanting the best that money can procure, and we doubt not that under his management the company will, as heretofore, remain among the most substantial electric lighting properties in the country. At the same time we must express our gratification in these days of municipal ownership agitation that the city council of Providence has among its members men who are sufficiently intelligent and patriotic to weigh and determine the questions submitted to them in a spirit of fairness to the interests both of their constituents and of their lighting contractors. We feel certain that if every city in the Union had adopted the arrangement entered into by the city of Providence and the Narraganset Electric Lighting Co., by which the latter is limited to a profit of eight per cent. on its share capital in lieu of the grant to it of an exclusive franchise, very little would now be heard of municipal ownership of electric lighting plants in this country."

If, as shown in the above instance, the manager of a large and influential electric lighting company has found it much more to the interests of all concerned to endeavor to please the public as far as he can, instead of abusing the privileges accorded him, is it not apparent that for those cases where disputes are now in progress between the municipality and the local lighting company every possible effort should be made towards effecting an amicable settlement, before arbitrary measures are resorted to by the former? Not only in this one instance, but in numerous others as well, have the beneficial results of intelligent, impartial and amicable investigation been clearly and conclusively demonstrated, and there can be no doubt that if the company will show due consideration for the rights of the public at every available opportunity, the latter will not be slow to accord privileges and favors, which under less agreeable circumstance would be denied, perhaps with much indignation.

Where negotiations are to be made between the municipality and the company, the latter has every right to demand that those appointed to advocate the interests of the former, shall be men whom, as far as possible, are capable of conducting an intelligent and competent inquiry, without prejudice to the rights involved, and as the public demand full justice, sometimes with unnecessary vehemence, let them consistently endeavor to provide that justice, in the strictest sense of the term, shall be obtained, not only for the one side, but for both.

(To be continued.)

—Now that Anglo-Saxon unity is becoming a favorite catch word with such as are in high places watching to see which way the wind blows, the people of Toronto are beginning to realize the benefits they have unwittingly conferred upon the Empire and the race by allowing Architect Lennox his own sweet way in building the city hall. Such a combination as it is of Canadian hard-earned gold and United States ready-made fixtures and materials will be a monument to our desire to freely give and take as our neighbor sees fit. Having provided such a monument, we hope that the corpse of the desire will be carefully interred under it, and that in future when Canadian manufacturers tender at less prices than their neighbors for articles of the same class, their tenders may not be rejected merely because the tenderers are not aliens and their wares are not made in the United States.

A POLE RAILWAY.

From Weymouth, N.S., to Nouvelle France, a distance of sixteen miles, there is a railway whose construction and equipment are of great interest to the lumber trade, and in fact to all who are engaged in opening up new or sparsely settled districts. This pole railway was

A Pole Railway in Operation.

built by Emile Stehelin, of Nouvelle France, N.S., who has kindly given The Canadian Engineer some details of this novel work. The line serves six stations in its course: Nouvelle France; Doyle Lake, where there is one sawmill; Riverdale, where there are two sawmills; Woodville, where there are three sawmills; Corberrie, a thriving little village, and Weymouth on the coast.

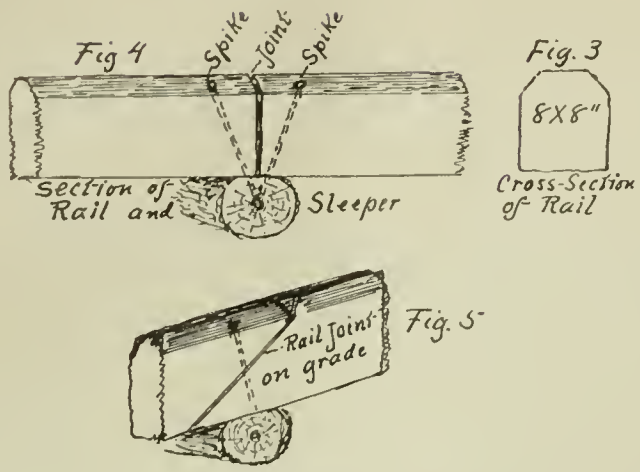
On level ground the construction of a pole railway is a very easy matter, but in this part of Nova Scotia the country is hilly and there are a great many swampy stretches which made construction more expensive than would often be the case. The cost of the whole line, including equipment in this case, was about $3,000 per mile. This included grades of three to six per cent., a number of bridges and several embankments of from ten to fifteen feet high. On level ground the construction con-

A Pole Railway—Construction.

sists in laying down sleepers ten feet long and three to four feet apart, on which is laid a spruce rail, sawn as shown in Fig. 3. The rails are twenty to thirty-five feet long, and are trimmed square for flat stretches and bevelled for grades as shown in Figs. 4 and 5. The joints are made and the rails secured by twelve-inch wharf spikes as shown.

The method followed in building bridges and embankments is to lay a series of timber floors one upon another, each at right angles from the last, till the required height of the pier of embankment is obtained. With careful work and exact cutting of the timber, there is practically no limit to

the height to which such piers and abutments can be carried.



The locomotive "Firefly," shown below, is the one first used by the road. This is an old stationary boiler and a twenty horse-power engine, mounted on a truck. The wheels are driven by an intermediate crank wheel. Considerable difficulty was experienced in adjusting the parts of this engine, but it was finally got to run very satisfactorily, and is used for hauling logs to the sawmills.

A Pole Railway—The Locomotive "Firefly."

The "Maria Theresa," shown below, is an entirely new locomotive, built expressly for the line by a Nova Scotia firm. It has four cylinders of twenty horse-power each, driving two trucks of four wheels each.

In operating a line of this kind, one of the greatest difficulties to be contended with is the amount of friction developed by the wheels, which do not run on the wooden rails with at all the same ease as on steel or iron. The

A Pole Railway—The Locomotive "Maria Theresa."

locomotive should, therefore, be made as light as is consistent with the power to be developed, the friction of the wheels being sufficient to compensate for the lack of weight in the locomotive. It is to obviate as much of this friction as possible that the upper surface of the rail is cut in three faces. At present, only six miles per hour is obtained regularly, but Mr. Stehelin hopes with some modification of the locomotive wheels to obtain higher speeds. The engines are wood burning, but it is proposed to substitute coal, which can be had very cheaply at Weymouth. The freight cars used on the pole railway are twenty feet long on two trucks with four wheels each; the passenger car is twenty feet long, and is covered and closed; there is also one small passenger car to carry four persons.

CHROMIC IRON IN CANADA.*

For a long time chromic iron was regarded only as a mineralogical curiosity, and its industrial use only became known when it was applied to chemical industries. The application of the salts of chrome to dyeing dates from 1820, and the industry of the manufacture of bichromate of potash was inaugurated about that time. It was only in 1883 that potash was partially replaced by soda. Down to 1827, the very limited consumption of this product was supplied from the region of the Ural Mountains. In 1827, chromic iron was discovered by Isaac Tyson, jr., in the neighborhood of Baltimore, and subsequent search resulted in further discoveries of it in other parts of Maryland and Pennsylvania. From that time to 1862 the Baltimore region supplied the market in the United States and Europe, the most important centre of consumption in the latter being Glasgow. In 1845, Mr. Tyson, in order to utilize his surplus output, established the manufacture of bichromate of potash, which is still in operation in Baltimore under his direction. In 1848, the deposits in Asia Minor were discovered, which, ten years later, became, so to say, the most important factor in the production of chrome in the whole world. In 1869, discoveries of the ore were made in California, which have supplied the American industry from 1878 down to these latter years, and next in New South Wales and New Caledonia, and lastly in Canada and Newfoundland in 1894.

Chromic iron, or chromite, has a density of 4, 5, say about 7 cubic feet per ton, its hardness is between 5 and 6, it gives a brown stripe and dust; it is unattackable by acids and infusible at the highest temperatures. Some authors say that it is sometimes magnetic, but J. Obalski, M.E., in describing the deposits in Quebec, did not observe that it was so in that region. It is true that some samples of magnetic iron in the serpentine contain chrome, but, at least for the Quebec district, its non-magnetic condition is a distinguishing characteristic of ores that can be worked for chrome; its appearance moreover is that of magnetic iron or titanic iron. It is composed of iron in the state of protoxide and sesquioxide of chromium; nevertheless the elements, iron and chrome may be, in part, replaced by magnesia and alumina, which then reduce its grade, without prejudice to the mixture with the serpentine, which is moreover easy to discern. Theoretically it may be said that the yield in sesquioxide is 68 per cent., but it is rare for the real grade to exceed 56 or 57 in picked specimens, and the industrial tests on shipments very seldom reach 53 or 54. The merchantable grade for the manufacture of bichromate of potash is 50, but some buyers accept 49 and even 48. Under that, the ore is classed as of inferior quality. The Black Lake ores have given 49.8 and 50.3 on shipments (analyses of the Baltimore chrome works), and 54 and 56 on specimens (Donald analyses) 58.06 (Pittsburg testing laboratory), concentrated specimens from Black Lake 56.28 and 60.66 per cent. (Ledoux &

*The facts here presented are taken from a recent report by J. Obalski, M E Provincial Inspector of Mines for Quebec.

Co.). Milton L. Hersey has also made numerous analyses of these ores, which frequently gave high grade. Shipments from Breeches Lake have reached 55 per cent. In chemical industry, the ores which are poor in silica are preferred, and for certain uses buyers fix a limit of 12½ per cent. of metallic iron and 8 per cent. of silica.

The existence of chromic iron in the serpentines of the Eastern Townships, of Quebec, has long been known, but until 1894 hardly any effort was made to develop the deposits. According to the geology of Canada for 1863, the first attempt in that direction was made in 1861, when about ten tons were extracted in the neighborhood of Lake Nicolet. Some twelve years ago, a small quantity was also taken out in lot III, 24 of Wolfestown, and in 1887 Dr. J. Reed shipped to Philadelphia 54 tons derived from lot X, 1 of Leeds. Lot IV, 16 of Thetford, also yielded four or five tons, but of low grade. About the same time, specimens sent to Antwerp Exhibition had attracted attention, and orders for ore had been received, but the known deposits did not appear to be rich enough to be worked with profit. In April, 1894, an unknown mineral having been discovered near Black Lake by a man named Provençal, a specimen of it was brought to the office of the Provincial Mining Engineer, who at once recognized it as chromic iron of a high grade, and advised that the mine should be worked, indicating at the same time where a market could be found for the product. The Nadeau-Provençal mine was thereupon opened; and the selling price of the ore being deemed remunerative, prospectors entered the field and other discoveries were made in the neighborhood, especially in the township of Colraine, thus giving rise to an industry which promises to become prosperous.

The presence of these deposits is indicated by a sort of black spongy crust, of ferruginous aspect, appearing in spots on the serpentine and by the loose rocks found on the surface. Sometimes the crusts are only superficial, and at others they penetrate into the serpentine with a thickness of several inches, which may increase and attain several feet. In still other cases, the mineral shows itself at once on the surface with its metallic aspect and occasionally in its greatest thickness. But the deposits have a character of irregularity; they seem to be almost independent of each other, and sometimes suddenly disappear without leaving any trace to warrant further work. No defined walls except the planes of ordinary fracture in the serpentine are observable. The question of the depth to which these deposits extend has been mooted, and it has even been suggested that borings should be made to determine whether they cannot be found where they do not outcrop at the surface. Such deposits should exist and chromic iron has been found at a depth of 30 feet in an otherwise unproductive shaft sunk for asbestos by the Beaver Asbestos Co. on lot Colraine C. 30. Geologists have given considerable study to the origin of this mineral, and have established, in the Quebec region at least, that while it occurs in the dark green serpentines of the Eastern Townships, it is absent from the buff or honey-colored serpentines of the Laurentian system.

Chromic iron is also further found on the west coast of Newfoundland, at Bluff Head, Port au Port Bay, where a very important bed is being worked by the Halifax Chrome Company, which during the summer of 1896 took out 1,500 tons and shipped about 200 gross tons, of which 145 went to Pittsburg, where it yielded 49.90 per cent. (Transactions of the American Institute of Mining Engineers, Geo. W. Maynard). The author of this paper says that the ore gives from 39 to 50 per cent., and he mentions the discovery of a mass 97 feet long by 45 feet wide.

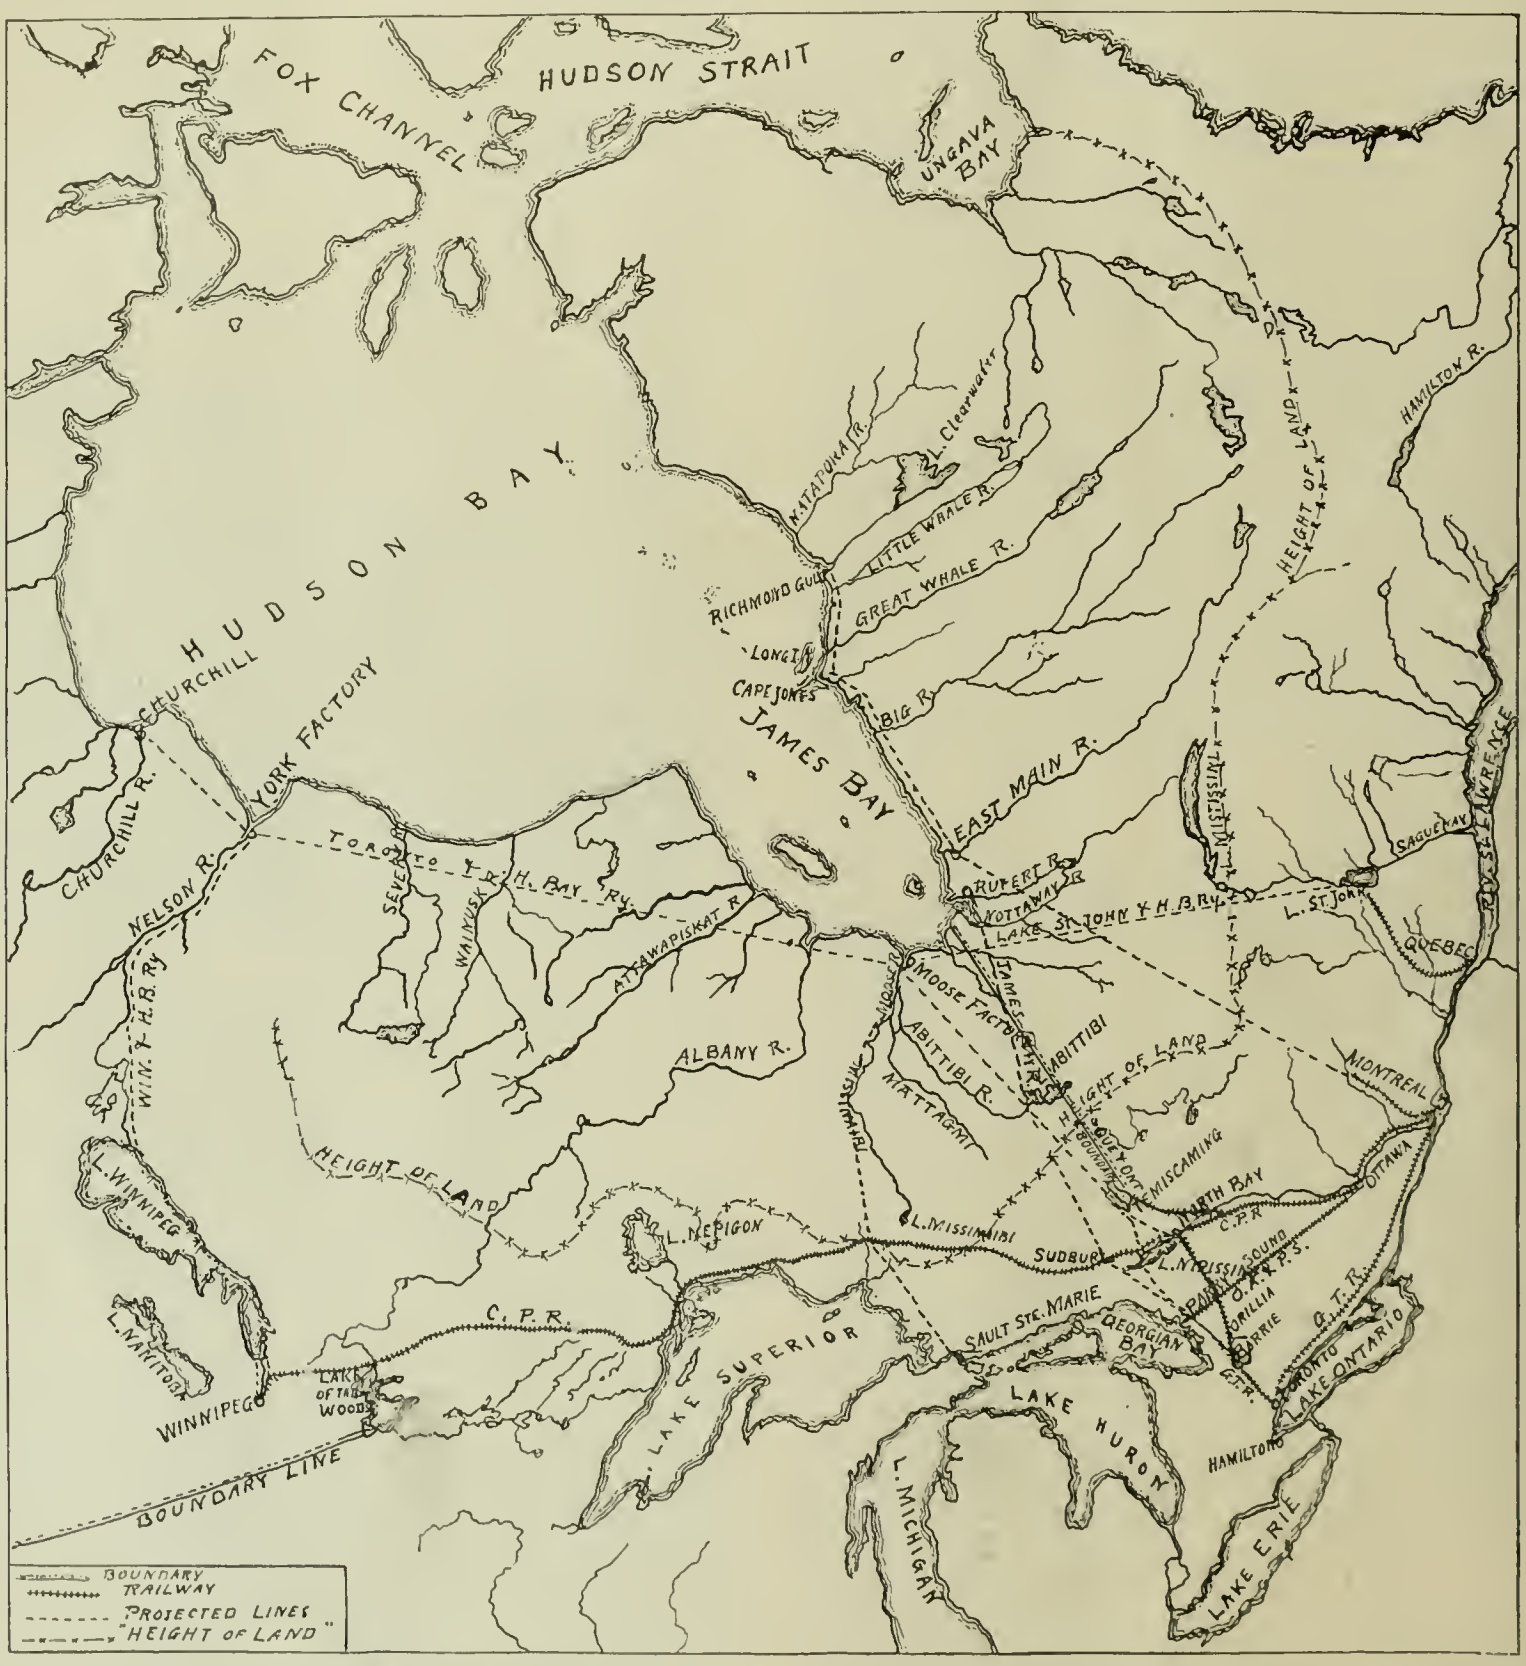
With these deposits in Canada, there seems no reason why a great chemical industry should not be built up in Canada, along with a considerable addition to our mining development. Chromic iron is used for the manufacture of bichromates of potash and soda, which are employed in the dyeing and printing of calicoes. These products form the bases of the chrome colors, yellow, orange, green, etc.; they are also utilized in the construction of certain batteries of electric piles, in the tanning of leather, in chemistry, and slightly in medicine. Chrome enters into the composition of the ferro-chromes, which are used to make the chrome steels that are noted for their very great hardness, and employed for the armor plating of vessels and forts, and for the making of shells, tools for cutting iron, shoes and dies in stamp mills, safes, etc. Ferro-chromes of different grades, ranging from 40 to 90 per cent. of chrome, are made while the chrome steels contain from 1 to 10 per cent. of chrome. They are also employed in alloys with aluminium. Chrome imparts to the metals with which it is allied great hardness and inalterability, and increases their elasticity, these qualities varying with the grade in chrome. More recently low-grade chromic iron has been employed on account of its essentially refractory qualities, in the construction of certain parts of furnaces exposed to high temperatures, and especially in the construction of the inside parts of open hearth furnaces and of reverberatory furnaces for copper smelting. A certain quantity of it is regularly used for this purpose in the Pittsburg district, where also special chrome fire bricks are manufactured, two companies being engaged in this industry. In this case, the medium grades are preferred, on account of the price. In latter years about 2,000 tons have been used in the United States for these purposes. It is also employed by the European metallurgical establishments.

In the Province of Quebec there is a pretty extensive region in which chromic iron occurs in commercially workable quantities, and when it is considered that these deposits are located at distances ranging from several acres to five and nine miles from the line of the Quebec Central Railway, and on heights which render their working easy, that labor on the spot is cheap and fuel wood close at hand, it would appear that it would be difficult to find a more favored country as regards this industry. It has been prosecuted there since 1894, but by very primitive methods, not a single steam machine having been yet employed; nevertheless over 10,000 tons have been taken out to a value of about $140,000. Nova Scotia coal is worth $4 a ton at the Quebec Central Railway. Furthermore, the chromic iron ores of the region in question are concentratable and capable of furnishing a very large quantity of high grade. The Government still owns many lots, which can be fully bought out at $400 per 100 acres. There have been no deep workings yet, and it is safe to conclude from what has been said that this district is destined to become an important factor in the production of chromic iron for many years to come.

ON TO HUDSON BAY.

Hudson Bay, Canada's great inland sea, is about 600 miles across from east to west, and measures about the same distance from north to south, or if you include James' Bay, its southern arm, it will be 1,300 miles long from its northern to its southern extremity. Its average depth is 600 feet, and its floor is so level and uniform that if it were raised out of the water it would form one vast prairie

like that of Manitoba. The waters of James' Bay, however, are so shallow (except through one wide channel leading down its centre to Moose Factory), that a boat oar can touch bottom many miles from shore. This vast inland ocean is a basin into which 3,000,000 square miles of land are drained, and so large is the quantity of fresh water pouring down, that the waters of James Bay are only slightly salty. Hudson and James Bays receive the waters of twenty-five large rivers besides those of numbers of smaller rivers, some of which are unknown and unnamed. Notwithstanding the vast area of Hudson Bay (about 500,000 square miles), no part of it is within the Arctic Circle. The resources of this vast region are climatic features of the great inland basin as to discourage inquiry. Hence it is that many intelligent Canadians imagine that the waters of Hudson Bay form one immense ice field during the greater part of the year. As a matter of fact, Hudson Bay itself is never frozen over any more than Lake Huron or Lake Superior. Navigation can be carried on throughout Hudson Bay proper every day in the year. It is only in Hudson Strait that difficulty from ice is encountered. In James Bay, owing to the shallowness and freshness of the water, ice is formed during the winter, but this ice with the river ice breaks up in April and May at about the same date that the St. Lawrence River is free from ice. The trouble



only now being faintly realized. We now wonder that the natural fertility of Manitoba and the North-West Territories, and the great mineral resources of British Columbia and the Yukon, remained so long unknown, or, at least, unappreciated by the people of the older Provinces. In a few years when the great valley of James and Hudson Bays shall have been opened up by railways, we will wonder still more that it, too, should have remained so long locked up. The reports of early travelers and explorers, who, in order to make interesting stories, have exaggerated the character of the climate, have no doubt been one of the stumbling blocks in the way of opening up our great northern land. The climate and surroundings of Hudson Straits also have been so confounded with the in navigating Hudson Strait is not from locally formed ice, but the great polar ice fields that are annually broken up and drift down Davis Strait and Fox Channel, where quantities of it are deflected by the inset of the Atlantic tides and turned into the Strait. The length of time when the Hudson Straits are navigable, varies according to different navigators and explorers all the way from $3\frac{1}{2}$ to $6\frac{1}{2}$ months in the year. Notwithstanding the pessimistic views of many regarding these Northern waters, the fact remains that though Hudson Bay and Strait have been navigated continuously since 1668, when the Hudson Bay Company was formed, the shipping disasters have been remarkably few, so few indeed that for the last half century the Hudson Bay Company has ceased to pay insurance on

its vessels, having found it cheaper to assume its own risk. Dr. Bell, the Dominion Government explorer, agreed with the reports of those who have spent years in residence on the shores of the Hudson Bay, that these waters are remarkably free from violent storms, particularly in summer months. Taking all months of the year together, the Hudson Bay is a mill pond compared with the north Atlantic, while the total hours of fog in the year are only one-third those of that part of the Atlantic through which most of our present ocean steamship tracks are mapped. These are important points which are now beginning to be realized by Canadians.

When we come to the question of climate, we must remember that we are dealing with a stretch of country nearly 2,000 miles from north to south if you take the Height of Land of northern Ontario and Quebec as its southern boundary. There must of course be a considerable variety of climate in so large an area. Taking the country from the Height of Land to the northern part of the James Bay on both the east and west sides, we have the most positive evidence of a climate as temperate and healthful as any part of the St. Lawrence Valley or that part of Ontario between the Ottawa and Georgian Bay. The voyageurs who accompanied some of the Dominion Government explorers to the James Bay were surprised at the mildness of the climate and the high summer temperatures of the water, compared with their experiences along the shores of Lake Superior where most of their life had been spent. This is accounted for partly by the greater length of the summer day in these northern regions and partly by its nearness to the level of the sea. Dr. Bell found the average temperature of sea along the east coast of the Hudson Bay to be 53 degrees Fah. and of the rivers 61 degrees, and he and his party bathed in the sea almost daily on their journeyings along the coast. The various farm and garden products that have been grown for the last half century or more by the Hudson Bay factors and the missionaries around the Bay, and the character of the forests, are further evidences of the suitability of the climate for successful settlement. Starting from the Height of Land in either Ontario or Quebec, the traveler passes through an extensive shallow basin, comprising not only vast tracts of splendid agricultural land, but numberless lakes of all sizes linked together by rivers and streams. From the northern rim of this broad basin the land again slopes gently towards the shore of James and Hudson Bays, cut through here and there by rivers. These numerous rivers, though navigable for stretches 100 miles or more, have numbers of falls and rapids, which, while they are an impediment to navigation, give promise of immense industrial advantages in the creation of water powers. On the Abittibi one exploring party had to make 21 portages, owing to the rapids, falls or chutes, some of which could be transformed into ideal water powers. There is probably no similar area of country in the wide world capable of yielding such an enormous amount of water power for industrial purposes. Right here we may say, that in view of the illimitable area of splendid spruce land and cheap power in this region a railway through the Hudson Bay Territory could be made a profitable investment if the wood-pulp industry alone were in question. The finest spruce in the world is to be had in these northern forests, the extent of which is beyond estimation. White and black spruce and the larch tree thrive well up to a point north of Richmond Gulf, and when this line is carried some distance inland eastward it again curves north to Lat. 59, or to a point north of Cape Dufferin. Balsam, poplar, canoe birch, aspen, mountain ash, balsam fir, bird cherry and Banksian pine, have their northern limits at various points farther south on the shores of the James Bay, but in each case this limit is also extended farther north as you go inland to the east and west of the Bay. The white cedar, mountain maple, white and red pine, white elm, red oak, ironwood, basswood, birch, ash, and other deciduous trees are to be found in areas of varying extent from the head of James Bay down to the settled districts of Ontario and Quebec. J. C. Bailey, who was on the exploration for the Nipissing and James Bay Railway, found splendid specimens of Norway pine, yellow and black birch, and sugar maple, many trees measuring from 20 to 40 inches in diameter, and standing 70 to 80 feet high. As to the soil, almost every traveler and explorer has been surprised at its fertility and the depth of vegetable mould. Dr. Bell, in his report to the Government on the country between Lake Superior and James Bay, says: "After passing the 'swampy grounds,' the traveler cannot fail to be struck by the abundance and fertility of the soil exposed on the banks of the rivers all the way to Moose Factory. I have no doubt that at some future time this country will support a large population." Among the agricultural products that have been grown year after year at various Hudson Bay Company's posts, and by missionaries living among the Indians, may be noted barley, oats, rye, peas, beans, melons, cucumbers, castor oil beans, tobacco, balsams, cauliflowers, cabbages, lettuce, turnips, radishes, beets, carrots, onions, coleworts, cranberries, gooseberries, currants, strawberries, raspberries and cherries. Wheat has also been grown at the Hudson Bay posts. Sarsaparilla of a very superior quality grows wild over a wide area of country. Archbishop Tache gives at least 223 species of birds, and 72 species of fur-bearing animals to be found in this region. The wealth of the Hudson Bay district in fur is too well known to need emphasis here. Agriculture in the Lake Temiscaming and Temagam districts has passed the experimental stage, tracts of land having been brought under cultivation, the farmers finding a market in the supply of men and horses engaged in lumbering operations there. An abundance of hay is grown, the clover of the Temiscaming district being said to to excel that grown in any other part of Canada. Root crops are successfully raised. Of oats, barley and peas the farmers have large harvests; cultivation of wheat is alone limited by the narrowness of the market. All that is wanted to place agriculture in this district upon a well established basis, and open up the rich territory around Lake Abittibi to the north, is efficient railway communication with the commercial centres of the Dominion.

We now come to the mineral features of the Hudson Bay slope, and here it must be remembered that nine-tenths of the country has remained until now absolutely unknown and untouched by the geologist or prospector. The cursory examination of this one-tenth of the region in question has disclosed the following minerals:—gold, silver, lead, iron (magnetic and hematite), nickel, copper, pyrrhotite, zinc, galena, antimony, arsenic, tellurium, platinum, tin, bismuth, molybdenum, cobalt and manganese, while among the non-metallic minerals may be noted agates, carnelians, epidosite, porphyries, granite, syenite, sandstone, quartzites, flagstones, slates, marbles, ornamental argillites, jaspers, garnets, chalcedony, white quartzites for glass making, asbestos, graphite, actinolite, lithographic stone, gypsum, salt, amethysts, soapstone, ochres and other mineral paint material, kaolin, lignite, mica, peat, axinite, limestones, brick clays, petroleum, and last of all anthracite. When we consider how slight has been the geological examination of this region, the foregoing list is certainly imposing, and of the minerals here enumerated

NEW VICTORIA JUBILEE BRIDGE ON G.T.R., AT MONTREAL—VIEW FROM HARBOR GUARD PIER.

at least one-half are known to exist in paying quantities. In some cases the deposits are of incalculable extent, and all that is wanted is railway communication to develop them. The copper belt, a large part of which is nickeliferous, extends all the way from Lake Huron and Lake Superior to Lake Mistissini. Antimony was found near Echo Lake in a vein eight inches wide of very rich ore. On Moose River the gypsum beds are ten to twenty feet thick, and have been traced for many miles from the river. Carniferous rocks are extensive to the south west of James Bay, and in this formation it is expected oil will be found, as in like formations in the Enniskillen fields of Ontario. Large deposits of clay iron-stone are found on the Mattagami River. The ornamental stones alluded to in the non-metallic list are found in remarkable abundance in many places, while some beautiful varieties of unnamed ornamental stones have been discovered. Samples of the granites have been polished and are said by experts to be finer than Aberdeen granite. Of the samples of marbles, some are banded, some clouded and all are easy to quarry. Some of the yellow ochres and Venetian red paints have been found in such a condition that they can be used without grinding. A bed of kaolin is found on the Missinaibi, below Coal Brook. It is overlaid by a bed of beautiful bright sand, of which E. B. Borron says, "I believe that both the kaolin and sand, the one suitable for the manufacture of porcelain and the other for window glass, are there in large quantities." Lignite is found on the Mattagami, the Missinaibi, and the Abittibi, and the beds of peat are declared to be "absolutely inexhaustible." Of other beds of lignite, Dr. Bell mentions some that are 1½ to 6 feet thick. The sample of anthracite found on Long Island, and shown to Dr. Bell, has a conchoidal fracture and a bright lustre, and on analysis yielded 94.91 per cent. of fixed carbon, and only 0.35 per cent. of ash. Dr. Bell was prevented from visiting the locality, but this discovery is of the highest importance to both Ontario and Quebec. On the Abittibi River, the bituminous limestones and carbonaceous shales closely resemble the petroleum-bearing strata of the MacKenzie Basin. Mr. Low, who explored the south side of Hudson Straits last year, says "the schistose rocks of that region are frequently penetrated by numerous quartz veins, and their proximity to masses of igneous rock are conditions favorable to the occurrence of gold. Along with this schistose are large beds of impure iron ore, corresponding with the enormous deposits of bedded iron already found in the Cambrian rocks of the Koksoak and Hamilton Rivers." The clay deposits of Lake Abittibi are unusually rich in aluminum, and this industry alone should justify the exploitation of that region. A sample of the manganiferous spathic ironstone, which is found in such great abundance, was shown on analysis to contain 25.44 of metallic iron and over 24 per cent. of carbonate of manganese. A band of chalcedony seven feet thick was found by Dr. Bell on one of the islands north of Richmond Gulf. "The spathic ironstone bands of the whole Nastapoka chain are found by Dr. Harrington to constitute valuable iron ore. These form a band averaging 20 feet thick throughout the whole group of islands, which have a length of about 90 miles exclusive of the islands to the north." The enormous abundance of the ore is its great feature, and we are told that not only is the ore already broken by nature in inexhaustible quantities, but much of it can be loaded direct into vessels from the steep, rocky sides of the islands. Magnetic ironstone is washed out of the drift in considerable quantities at various places along the coast. The rare mineral axinite, which has been discovered near the mouth of the Little Whale River for the first time in Canada, is found in crystals along with quartz, calcspar, epidote, chlorite and asbestos, also in the granular form. It is of purple color and takes a high polish.

This mere outline of the minerals found in the James and Hudson Basins will show that Canada has more than one Klondyke; and when it is considered that only a few years ago the large areas of gold and nickel of northern Ontario were unsuspected by the geologists who had traversed the region, it is but reasonable to expect that new minerals will be found and more expensive deposits of those already known will be unearthed in the region under consideration.

The accompanying sketch map is intended to show approximately the routes of various railway lines projected towards Hudson Bay from Ontario and Quebec. The conformation of the country, the abundance of timber, and numerous water channels, render railway construction in this country a most easy problem. The surveys already made show that the highest grades going north from the Height of Land are not more than 1½ to 1.33, and going south not more than 1 per cent. The total elevation above the sea of this Height of Land averages from 850 to 1,200 feet. Though the road projected from Missinaibi is the shortest, it is perhaps not the one best calculated to bring the resources of these northern latitudes to the marts of Ontario and Quebec. The lines extending from North Bay in the one case, and those projected from Lake St. John or Labelle on the other, are the ones most likely to be looked on with favor by the people of Ontario and Quebec to start upon. The commission, of which W. T. Jennings, C.E., is secretary, appointed by the Toronto city council, has done solid public service by bringing this question forward recently; while the James Bay Railway Company, backed by Senator Geo. A. Cox, Wm. Mackenzie and Geo. H. Bertram, M.P., has obtained a bonus from the Ontario Government, and it is said the Dominion Government has also promised to assist in the undertaking. The citizens of Toronto, along with other Ontario cities, are now awakening to the possibilities of this new land, and one may hope they will no longer deserve the caustic comment of Mr. Paterson, who, in discussing the subject, said: "Many rich Toronto merchants would rather sit down on a few corner lots in the city and wait until they rise in value, and aldermen would rather squabble over putting on or taking off half a mill of taxation, than stir outside and bring in trade." The city of Quebec is taking a lively interest in the subject, largely owing to the persistent advocacy of its city engineer, Charles Baillairge, C.E. It is hoped that both provinces will be emulous in pushing forward enterprises that are so certain to increase their population and develop their trade.

For THE CANADIAN ENGINEER.

REPORT ON THE PRECIPITATION SYSTEM OF SEWAGE DISPOSAL IN OPERATION AT HAMILTON, ONT.

BY W. M. WATSON.

During the month of March I visited and made a superficial examination of each of the two sewage works that are intended to clarify the sewage of about 35,000 out of the present population of 50,000 in the city of Hamilton, Ont., leaving the sewage untreated at the outfalls into the bay, at the foot of James street, Stuart street and Queen street, together with the large brick sewer that drains the whole of the mountain slope property and empties into Cootes Paradise. The small works at the east end of the town, on Wentworth street, was built early last year, and it is stated in the engineer's annual report for 1897, that they commenced operations on May 17th. Our readers will find a full description and illustrations of this plant in THE CANADIAN ENGINEER for January, 1897.

It is stated on page 58 of the annual report for last year, that from the date that the Wentworth street works commenced operation to the end of the year, they treated 114,114,000 gallons, or a daily average of 474,000 gallons. When describing the visit of the Toronto aldermen, to inspect the works, it is stated in the Toronto Evening News that the daily run of the sewage works is only ten hours out of the twenty-four each day, which means that only one set of employees is engaged and that for 14 hours each day the sewage passes over the underground overflow weir to the Burlington Bay, raw and untreated. On page 62 of the report it shows that the actual cost of operating the East end works for 220 days from May 17th to end of year was $4,470.87. Law cost, $704.28. The cost of construction and machinery is given at $38,000. The average cost per day for operating with one set of men 10 hours daily will be $20.32, and $7,415.84 for the whole year. Then add four per cent. interest on $38,000, the cost of plant, viz., $1,520, and allow ten per cent. on the wear and depreciation of value of machinery and works, $3,800, brings the annual cost of only clarifying the sewage at that small works for 10 hours each day from a population of about 12,000, and which appears to be void of trade or strong sewage, to $12,736.80, or over $1 per head. Should the works be run night and day, the management expenses would be double, and still the clarified sewage will go into the fresh water, unpurified, and containing most of the injurious and poisonous matter that is discharged from the skin and intestines of living creatures, jeopardizing the health of the inhabitants residing near the waters into which the clarified sewage is discharged, and afterwards setting up putrefaction, assisted by the lime that is used as a precipitant. If the amount treated, as stated in the report, is 474,000 gallons daily, it will amount to 173,010,000 a year, costing about $1 for each 13,600 gallons of sewage said to be clarified.

The works built at the foot of Ferguson ave. are similar in design and management, but are over double the size of the Wentworth street works. They have six settling tanks double the length of the three at the smaller works, and double the amount of machinery and appliances. They cost $42,000 to construct and are said to be capable of clarifying 3,000,000 gallons of sewage daily. We have no data to show the cost of management of these works, but experience would show that they will at least cost forty per cent. more than the works having less than half the capacity. They commenced operations early in March this year, and will be worked with one set of men 10 hours per day, as at the Wentworth street works. If then 3,000,000 gallons arrive at the works daily the average per hour will be 125,000 gallons, and for the 10 hours the works are in operation 1,250,000 gallons of sewage treated and 1,750,000 sent forward to the bay untreated per day. The Hamilton newspapers reported that a test was made by the engineer and part of the committee to prove the amount of sewage that actually came to the works, and they found that it amounted to 2,200,000 gallons per day at the Ferguson ave. works, or 800,000 less than the capacity of the works is stated to be. The population served by the two works is probably about 35,000 and the united cost of operating the two works 10 hours per day will be $30,600 per year, over 87 cents per head of contributory population, and if worked night and day, as they ought to be, the working expense will be double that amount, less interest on capital.

The sewage leaves the sewer and flows to a well, and is then lifted out by centrifugal pumps about 20 feet high and discharged into a wooden trough that leads it to the brick culvert that feeds the settling tanks. During the passage of the sewage from the pumps to the culvert lime an alum solution is dropped into the stream at the rate of 3½ grains of lime and 1½ grains of alum for each gallon of sewage. All the settling tanks stand full of sewage in a quiescent state, and the volume of sewage pumped enters the top of the settling tank through an opening about four feet wide, at a speed to all appearances of about twenty feet per minute, floating over the surface of the fluid at rest in the settling tank to the opposite end, when it passes through a similar opening made in the partition wall between tanks Nos. 1 and 2, then floats back to the commencing end, where it enters tank No. 3 and repeats the process until all the six tanks have been traversed, when it falls into the discharge culvert that is connected with a covered-in drain, which we suppose conveys it to the bay.

We expect that the stream of moving sewage will not sink more than one foot into the quiescent liquid contained in the tanks, or spread out over the surface more than 8 feet, and the rapidity of the flow will prevent the lightest solids held in suspension from settling down, so that the sludge extracted will be chiefly the heavy harmless grit or scouring dirt from roads, yards and floors, and the solids from the sewage that is allowed to rest in a quiescent state

in the tanks, while the bulk is flowing over the top. The alum was observable in the pressed sludge cake which had a clayey feel; but ammonia or urine usual in domestic sewage was not noticeable.

When comparing the sewage entering the tanks with the effluent leaving the last tank, No. 6, there was little difference in the appearance of the two samples, probably, first, because the flow was too rapid; second, because the sewage enters the settling tanks at the top when it ought to enter the bottom; third, because the precipitants are not in sufficient quantity or thoroughly incorporated before they enter the tanks; and, fourth, the lime solution is made from unslacked lime which will cause it to be attracted by the water rather than by the dirt composing the sewage.

We were informed that some improvements would shortly be made, and probably filters added to purify the sewage after clarification, as the engineer has been experimenting with great success in purifying sewage on Mr. Garfield's principle of passing it through pea coal, on the lines laid down in the September issue of THE CANADIAN ENGINEER. The design and arrangements of the works are such that they can perform efficient clarification, and when filters are added and the whole sewage that comes to the works treated and the overflow weir becomes useless, except when a big storm is in progress, then the $80,000 and cost of management will become a reasonable outlay, though just as good results might have been secured at a far more moderate cost.

The culvert carrying the effluent from the tanks to the bay should be open and made broad and shallow, so that the effluent could secure aeration during its progress to the bay and be easily inspected; also the by-pass channels and overflow weir should be open to view, so that they could be easily observed and show when all the sewage was passing through the works. Sewage, during and after treatment, requires all the atmospheric air it can secure. It is hard for a deputation to get at the true value of any sewage works in a two hours' visit, because any works or process can be made to work efficiently for a short period, but the difficulty is increased if the bypass, the discharge channels and overflow weir are not all open to sight. Moreover the assistance of an expert analyst should be had to show the exact contents of the effluent.

As previously stated in articles in THE CANADIAN ENGINEER, to clarify sewage it should remain at rest for some time, and if the continuous flow system be adopted, to save expense of a regular attention, then both ingiving and discharging flow should be thin and very slow, so that the volume of sewage resting is only very slightly disturbed and no perceptible motion created. The flow should be at a rate of about half a foot per minute, entering the full width of the settling tank near the bottom at the deepest end, and overflowing over a level lip the full width at the opposite end, and the quantity allowed to enter should be so regulated that it would be three hours before it reached the overflow. The Hamilton tanks can easily and cheaply be made to work on the continuous flow plan, and they can, as at present arranged, be worked on the quiescent system. Each settling tank would then work separately, as they ought to do, to perform good clarification.

We believe that each of the six long tanks at Ferguson avenue holds about 127,000 gallons; so to clarify 3,000,000 gallons in 24 hours the sewage should enter each tank at the rate of 170 gallons per minute, which would be sufficiently slow when the width of the tanks is taken into account. This should answer almost as well as the quiescent system worked with the float and discharge valves that are attached to each tank. When raw sewage enters at the bottom of a settling tank during the act of rising to the surface the suspended solids are encouraged to stay behind at the bottom.

Lime should not be used as a precipitant when the clarified sewage is discharged unfiltered, because it will not destroy microbes, but rather assist in multiplying them, and after a space of about two days, when the sewage effluent has mixed with fresh water, the lime will assist the clarified sewage to set up putrefaction, and the result will be equal to, if not worse, than would have been the case if the sewage had been well screened and passed in raw and untreated. The most suitable precipitant is stated by Mr. Slater, an expert in the sewage business, to be salts of manganese, which carry down the organic together with the dissolved suspended substances. It also destroys certain impurities by transferring to them a continual supply of oxygen from the atmosphere and from the air in the sewage fluid. This precipitant was expensive, but Mr. Adeney has found a substitute, by utilizing the waste products from certain iron works that are very rich in manganese, and which contain all the valuable properties claimed to be in the manganese compound sold as a sewage precipitant. An equally good precipitant may be made from the rust of iron, from iron ores or the refuse oxide of iron discharged from sulphuric acid works, dissolved by hydrochloric acid, which, when manufactured, is called perchloride of iron; $\frac{3}{4}$ of a pound will precipitate 1,000 gallons, it will never set up decomposition, and has great settling power. It could be made at a cost of $15 per ton.

With reference to the manufacturing of a solution of lime for use as a precipitant, we have found that the lime should first be slacked in thin layers with about 7 per cent. of water sprinkled on with a fine rose sprinkler, just sufficient to cause the lime to separate into fine powder, then bank it up into a heap and cover it over to keep in the steam, and allow it to remain in that position for over a week, or until it becomes thoroughly cooled. Afterwards mix it with the fluid at the rate of two parts fluid to one of lime, and mix it together well, when a solution is produced that is heavy enough to bear down and be attracted by the solids held in suspension by the sewage, and if the lime is delivered into the fluid sewage at the rate of eight grains or over of slacked lime to each gallon of raw sewage, and the lime solution is delivered into the sewage at the point where it enters the works, so that the action of the pumps and sharp angle movements will thoroughly incorporate the lime solution with every particle of sewage in equal proportions, and then the sewage is allowed to rest motionless for a short time, the lime will settle to the bottom of the tank, leaving a colorless clarified fluid behind it. But if sufficient be not put in, and it is not properly mixed with the sewage, or the solution is made from hot fresh unslacked lime, then it becomes saturated with the fluid, and does little or nothing towards compelling the dirt to separate from the water of the sewage.

It can be easily found out when the lime is properly incorporated with the sewage by filling a clear glass vessel with the sewage from the point where it enters the tanks. The liquid will appear full of small globules or flakes similar to the air during a heavy fall of snow. If the fluid is allowed to quietly rest in the glass, it will be seen that the flakes settle down to the bottom, leaving a clear fluid, which, though beautifully clear, is strongly tainted by urine and lime, and if preserved in a bottle it will soon be seen to ferment and change color, proving that it needs filtering, and that lime should not be used to clarify sewage if that sewage is discharged unpurified into fresh water. The

The Chemical and Metallurgical Building, McGill University

sewage at Hamilton did not show the presence of the precipitant when I examined it.

We have gone into the details of Hamilton sewage works as we found them when we had the privilege of inspecting the plant and process, and have used the printed reports of the city engineer to get at the expenses, and so give our readers the facts in regard to the purification system that is held up as a pattern, though the cost per head of population for construction of the plant is over $2.25, and the annual cost of management, including interest on capital, shows at least 75 cents per head for clarifying less than half the daily run of sewage. Granting that the sewage is really efficiently clarified, if purification filters are built and the sewage after being clarified is purified, then the cost to the ratepayers will be almost twice the present amount; and should all the sewage be handled that flows to the works the cost may be increased by one-half again, so that a stiff bill will have to be paid by those who adopt this system.

In Europe many millions of dollars have been wasted in the erection of useless and inadequate works, many fine-looking plants have been built and operated to mislead and keep the people quiet, by pretending to do a work that they certainly were not doing, and glowing and misleading reports have been published about them. But careful inspection by the government officials has shown these works in their true light. All the defects and the reasons for these expensive failures in Europe have been published, and Canada can have the benefit of the Old Country's fifty years' experience and experiments for nothing. She can avoid the expensive works and pitfalls, and adopt systems that have cost large sums of money to discover. It is a remarkable fact that the systems so far adopted by Canadian towns are the ones that are the most expensive and the least efficient of a majority of the methods at present in use in Europe.

Jos. Walker, of Parry Sound, Ont., fireman on an engine on the C.A. & O.A. & P.S. Railway, was instantly killed in a rear end collision last month near Parry Sound.

The bill to incorporate the Nickel Steel Company of Canada, provides that the company, with the consent of the Governor-in-Council, may lease or purchase the following lines of railway: Bay of Quinte, Central Ontario and Irondale, Bancroft and Ottawa Railway.

McGILL UNIVERSITY.

McGill University is one of the world's great universities, not only because of the massive piles which shelter its lecture rooms and laboratories, and the great money value which they represent, but on account of the standing in the world of intellect of the men connected with it and the enthusiasm which they bring into their academic work. The university is a monument to the liberality and public spirit of a large group of Montreal's most distinguished citizens. The first of these was Hon. James McGill, who, dying in 1813, left the manor of Burnside to endow a university in which one college was to be called McGill. From this beginning the present flourishing institution has grown up, and the original endowment has grown by gifts from private individuals from one hundred and twenty thousand dollars to almost four millions of dollars.

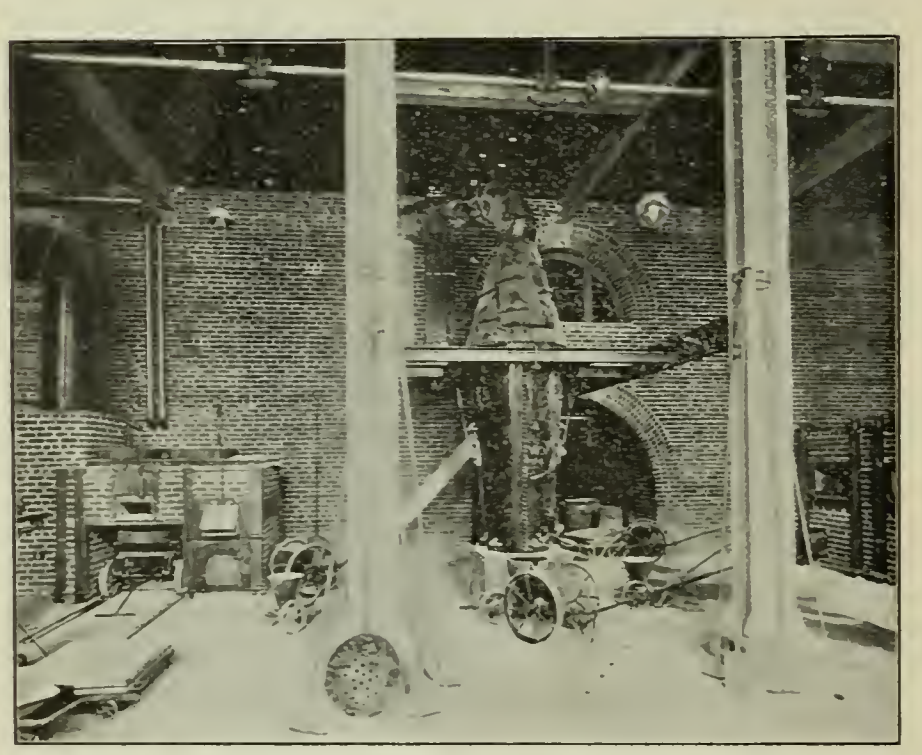
CHEMICAL AND METALLURGICAL DEPARTMENTS OF McGILL UNIVERSITY.

On the authority of Dr. W. C. Roberts-Austin, C.B., chemist of the British Mint, McGill University has now the best equipped metallurgical laboratory in the world. A similar remark might be applied to the mining department which has been in operation since March 1st. The mining department of McGill is splendidly housed in the McDonald Chemical and Mining Building, as shown in the accompanying engraving. The building is five stories in height, with basement and sub-basement. Extending from either side, at the back, are two large wings rising as high as the top of the ground floor. In these and in the rear part of the building are situated the principal rooms devoted to mining. There are the ore dressing room or mill, the smelting room, the metallurgical laboratory, the assay laboratory, wet assaying rooms and the teaching departments. These occupy a floor space of about thirteen thousand square feet.

The ore-dressing room has a twenty-foot ceiling and occupies the whole north wing. Here the ores of silver, copper, etc., and gold-bearing quartz in the condition in which they leave the mines, are received, and turned out metals in a form suitable for the furnace-room. The ores of gold, silver, copper, lead and iron are most important—but others can also be treated by this plant. It is full size

ASSAYING ROOM—MINING AND METALLURGICAL DEPT.—McGILL.

and differs from the ordinary mine equipment in that it is much more extensive. The usual commercial plant is designed as a matter of course to treat the ore of one mine, but the McGill appliances are sufficient to treat any kind of ore found in the Dominion of Canada. The student trained here will thus be at home with any first-class mining plant, and the plant at McGill being devoted to research and investigation only, unlike the average commercial plant, will be the means of producing many improvements in the methods of ore treatment now in vogue. The equipment consists of three rock crushers, known as "Blake," "Dodge" and "Comet" machines; two batteries of stamps, one of five five-hundred-pound



FURNACE ROOM—MINING AND METALLURGICAL DEPT.—McGILL.

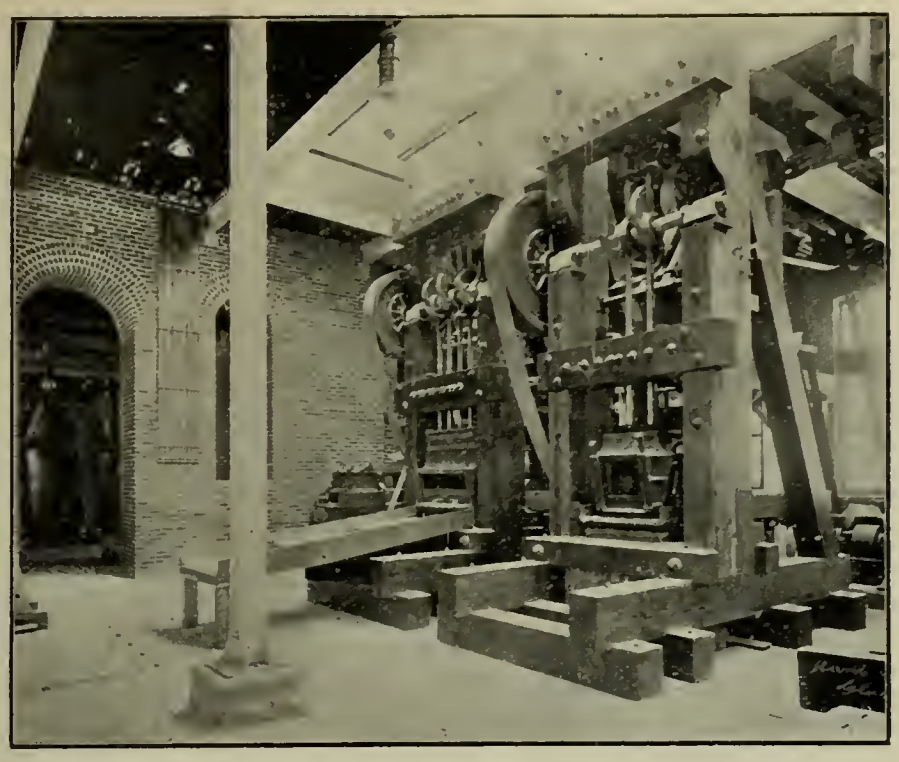
heads, the other of two of a thousand-pound heads each; a Huntington mill; coarse and fine crushing rolls; trowels and sieves; Hartz and Collum jigs, revolving, bumping and belt tables, and various pieces of apparatus such as magnetic separators, etc.

The crushers reduce the large fragments of rock to make easier the separation of the metal. The machines consist essentially of jaws moved by levers of great power. Into these the large pieces of ore fall, and are broken to a size convenient for the separating machines. The crushers are set in a high platform, the ore being carried up to them by means of a bucket elevator. The broken-up product of the crushers drops down, and is received in trucks which are capable of being rolled along the floor, or being hoisted up and moved about by the overhead system of travellers. According to its kind, the ore on leaving the crushers is carried to the stamp batteries or to the Huntington mill. Into either of these machines it is fed by an ore-feeder. In the stamp batteries the ore is pounded by swift blows from heavy hammers until it becomes a powder. Then, if it is gold ore, the mixed powder of gold and rock is passed into a quantity of mercury in a pan. The gold forms an amalgam with the mercury, and is held while the valueless rock is taken out. The heavy blows of the stamp battery are borne by a huge block weighing many tons, which extends deep into the earth. The Huntington mill accomplishes the breaking up of the ore in another manner, The ore being fed in falls into a heavy, tub-like receptacle, in which are four heavy iron disks attached to a shaft, in the centre, which revolves rapidly. The disks are so attached that they are free to move toward or away from the centre within the limits of the tub, but centrifugal force caused by the revolution of the shafts keeps them against the sides of the tub, and they revolve as they move thus in a circle. The ore is thus moved about inside, and is ground up into small fragments.

The methods of separating the ore from the rock involve a number of interesting machines. The Frue Vanner is one of these. It consists of a wide continuous sheet of rubber, with turned-up edges, stretched upon two revolving cylinders. One cylinder is lower than the other, so that the plane of the rubber sheet is inclined slightly. The broken mixture of metal and rock is fed upon the central part of the incline, and moves up (the sheet moving in that direction), until it encounters a spray of water which impinges on the sheet and carries down with it the rock. The metal being of greater specific gravity, holds its place on the sheet in spite of the water, and is carried until automatically washed off into a basin prepared for it. The jig separator is fed from three large hoppers connected to a revolving screen immediately above it. Through all its compartments water flows continually, and the ore is separated and sorted into the several qualities according to its specific gravity and size. The amalgamator and settler are rather complicated instruments, which extract gold from the slime resulting from previous separating processes.

As a preparatory process to treatment on the Rittenger table or Evans Buddle the pointed box may be used. This is a series of boxes or basins of conical shape, and varying in size. The sand from the stamp battery is fed

first into the smallest box, through which a stream of water is flowing so swiftly that only the largest grains are allowed to sink. The remainder is carried into the next larger box or basin, where the water spreading out has a less velocity, and the next size of grain is deposited, and so on.



Stamps—Mining and Metallurgical Dept.—McGill.

The Evans table serves to concentrate slimes and fine sediments on a circular bottom. It is a large round table sloping from the centre. As the table revolves the slime is fed upon it at the centre and flows toward the circumference, leaving in its progress the heavier portions of its constituents, while the surface is continually swept smooth by means of revolving brushes. Thus the particles of different densities are arranged in concentric circles, and can be carried by properly directed jets of water each into its proper receptacle.

The Rittenger table is a huge inclined plane of plate glass, which is jerked abruptly from side to side and mixed pieces of ore are sorted as they travel down its inclined surface, water flowing along with them. The repeated jerks cause the heavier pieces to travel steadily away from the lighter, and eventually the two come off the table at opposite corners. A good deal of the ore reduction machinery is supplied by Fraser & Chalmers, Chicago.

Adjoining the ore-dressing room is a second very large room used as the smelting room. Here the ores will be

Balance Room—Mining and Metallurgical Dept.—McGill.

roasted or smelted, which ever is necessary. The room will contain an English cupellation furnace, a reverberating roasting furnace, a Bruckner cylinder and a twenty-inch water-jacket furnace, as well as two-pot furnaces, each eighteen inches in diameter. Part is the tool room, and alongside is a small motor to run the machines in the immediate vicinity. The lowest floor of the south wing is taken up by the assaying rooms. In the dry assaying room are fourteen assaying furnaces of the best and latest pattern. Opening from it is the balance room. The apparatus of this room is of the sort commonly used in chemical laboratories, and the rooms themselves are nicely finished with white and buff-colored enamelled brick.

The portion of the building devoted to teaching, and designing and drawing rooms, is admirably arranged. The lecture room is fitted with numerous appliances for demonstrating the subjects taught, including an electric lantern for illustrations. Adjoining this is the office of Dr. Porter and his private research laboratory.

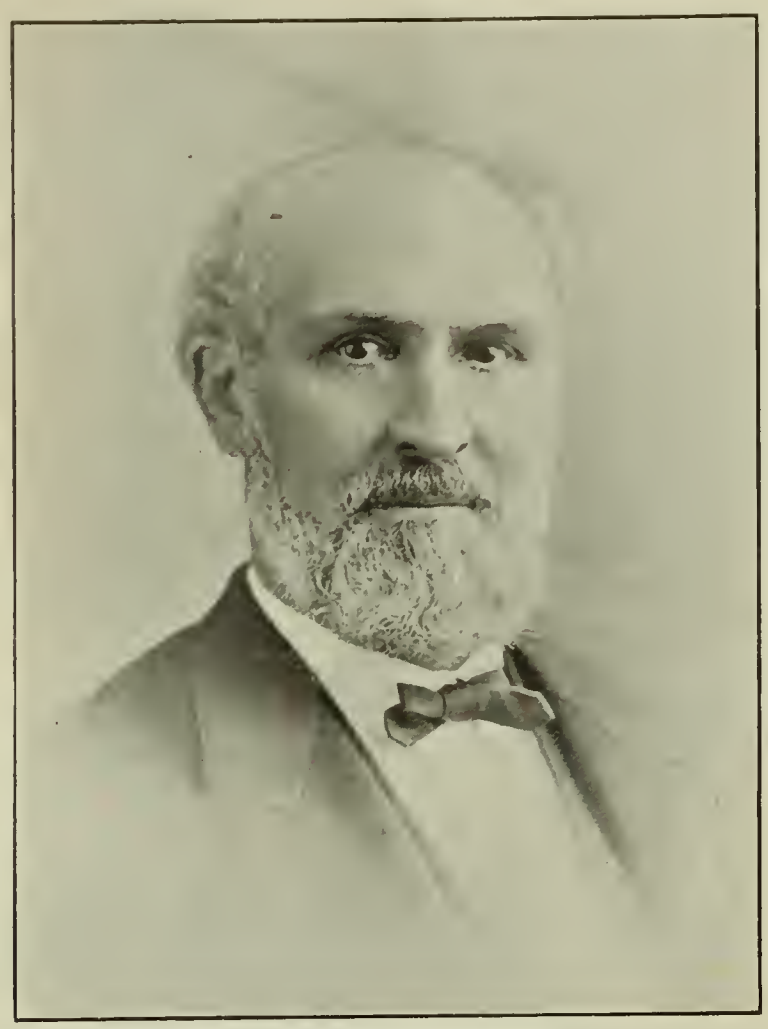
The portion of the building occupied by the chemical department is spacious and well equipped, and the ground floor and first basement floor are lecture theatres constructed on the latest plans. Throughout the buildings are lofty ceilings, ample lighting and modern appliances for ventilating and guarding against fires. On each of the three floors above the ground floor, extending all across the back of the building, is a large room—each of which is fitted up as a chemical laboratory, with every convenience and appliance which has been suggested by the experience of all the largest chemistry schools in the world. In addition to an unusual accommodation in

A Lecture Room—Mining and Metallurgical Dept.—McGill.

the line of draught cupboards for the carrying off of unpleasant or poisonous gases, there is a system of large flues in every part of the building connected to large ventilating fans in the roof. A noticeable convenience is a store-room on each floor adjoining the elevator. On the first floor in front are the offices of Prof. Harrington and his assistants and a commodious library and reading-room.

Among the many citizens of Montreal who have given largely for the provision of educational facilities in that city, none has been more generous in giving, nor has any one made wiser disposition of his gifts, than W. C. McDonald, whose endowments of McGill University now amount in buildings and funds to almost two millions of dollars, being more than has been given by any other Canadian to any educational cause.

Mr. McDonald is the youngest son of the late Hon. Donald McDonald, some time President of the Legislative Council of Prince Edward Island, and is grandson of Capt. John McDonald, 8th chief of the Clan Macdonald of Glenaladale, who after founding the Scotch settlements at Tracadie, Scotchfort, Glenfinnin and Fort Augustus, P.E.I., served during the American Revolutionary War as a



W. C. McDONALD.

captain in the 84th or Royal Highland Emigrant Regiment. He was born at Glenaladale, Tracadie, P.E.I., 1833, and was educated at the Central Academy, Charlottetown, also obtaining his business training in that city, under the late Hon. Daniel Brennan. He left P.E.I in 1854, and removing to Montreal became an importer and general commission merchant there. Subsequently, he embarked in business as a tobacco merchant and manufacturer, and now owns the largest tobacco factory in Canada. He is a governor of McGill University, a governor of the Montreal General Hospital, and a director of, as well as the largest shareholder in, the Bank of Montreal. He is an honorary member of the Architects' Association of Quebec. Among his gifts to McGill are : $20,000 to the Thomas Workman endowments for mechanical engineering; the erection and equipment of the W. C. McDonald engineering building, valued at $350,000, and an endowment for its maintenance ; the endowment of the chair of Electrical Engineering with the sum of $40,000 ; the erection and equipment of the Physics building, valued at $300,000, and two chairs of Physics, with endowments amounting to $90,000; the endowment of the Faculty of Law with $150,000; a further sum of $150,000 for the maintenance of the engineering building ; $50,000 towards the endowment of the Pension Fund, and the erection of a new building for the department of chemistry, mining and architecture, at a cost of $500,000.

The Goldie & McCulloch Co., of Galt, Ont., have shipped a big Wheelock engine to the Montreal Belt Line Railway Company. The engine weighed 19,440 pounds.

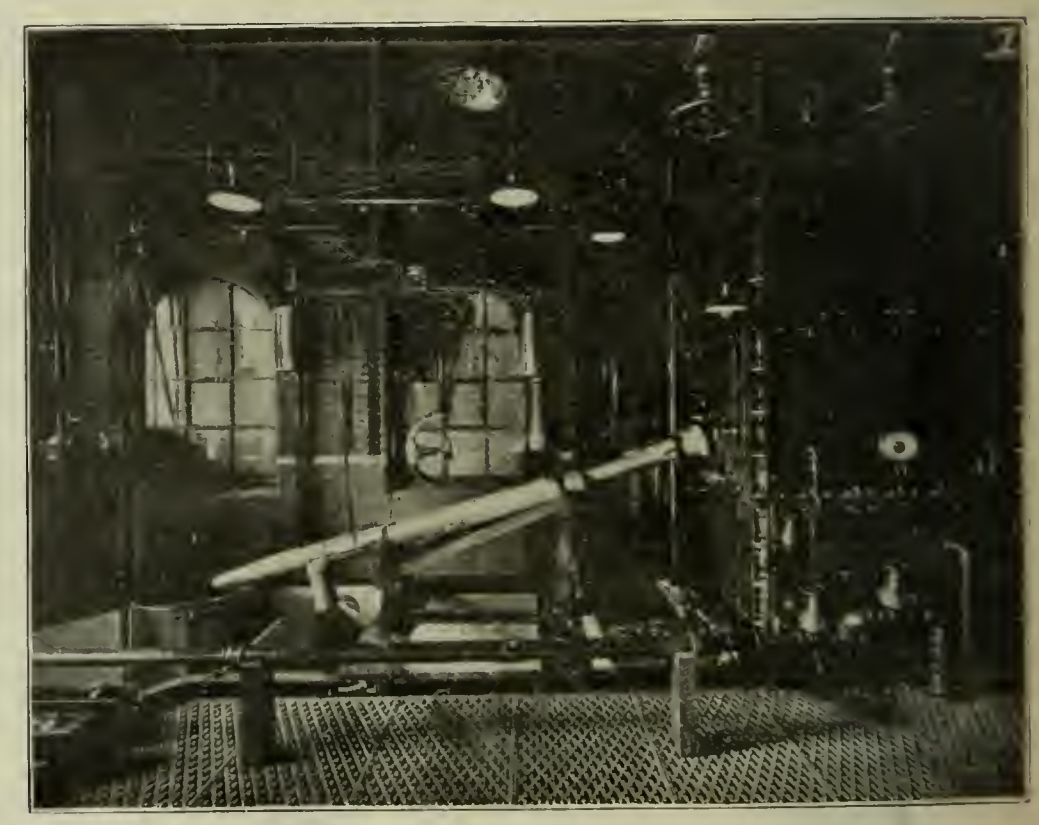
The Montreal and Southern Counties Railway Company, which obtained its charter last year, has been given power to extend its operations to the counties of Beauharnois, Chateauguay, Huntingdon and Napierville, and bonding powers increased from $20,000 to $25,000 a mile, in addition to preference stock, $10,000 a mile. There are extensive powers for connecting with other railway companies or crossing the St. Lawrence, and for amalgamating with other companies, but the company is debarred from running along the streets of Montreal or adjoining municipalities. Powers are also given to run steamers, maintain pleasure grounds, and sell electricity for light, heat or power.

HYDRAULIC LABORATORY, M'GILL UNIVERSITY.*

BY HENRY T. BOVEY, M. INST. C.E., LL.D., ETC., AND J. T. FARMER, MA E.

The laboratory is 39 feet in length and 31 feet in width. On the north side, near the centre, stands the experimental tank, having its base on a level with the bottom of a flume. The flume, which is 5 feet wide and 3 feet 6 inches deep, runs from the tank and terminates in an adjustable weir. The water flowing through the flume may pass over or under the weir and may run to waste or may be made to pass into five large carefully calibrated tanks, 8 inches below the floor level and ranged in series on the south side of the laboratory. The covering of the tanks is on the level and forms part of the floor. Over the easternmost of the tanks stand the experimental pump on a base formed of suitably designed carrying girders or trunks. The section pipes descend into the tank and thus allow the water passing.

On the west side, at convenient points along the flume, are the following pieces of apparatus: A 16-inch Pelton wheel, with brake attachments, a turbine tester of special design and an experimental centrifugal pump. Along the west wall is fitted up a Rife hydraulic ram with all the necessary pipes and tanks for experimental work. The pumps are driven from a line of 3½-inch steel shafting near and running parallel with the east side of the laboratory. The shafting is operated by a 100 h.p. Mackintosh & Seymour high-speed horizontal engine, standing in an adjoining room. By means of an electro magnetic coupling, designed by Prof. Carus-Wilson, and connected with a switch conveniently placed near the experimental pump, the main shaft can be almost instantaneously thrown in and out of gear, and without sudden impact or shock, as the circular armature permits a partial rotation until the resistance is overcome. A 90 h.p. automatic recording transmission dynamometer is placed on the shaft between the magnetic coupling and the nearest point at which power is transmitted. An 8-inch line of piping makes a complete circuit of the laboratory near the ceiling. The several pumps and motors are connected with this circuit, and the movement of the water is controlled by suitably placed 8-inch straightway valves, branch tees, elbows, etc. By means of a short vertical length of 8-inch piping,



terminating in a goose-neck, the pumps can be made to discharge into the top of the experimental tank, from which the water passes into the flume, then into the large tanks, and is thus again available for supply The whole of the water used in the laboratory is drawn from the city high level reservoir, which gives at the base of the tank a pressure of more than 120 lbs. per square inch. The city service is connected with the 8-inch circuit, which can therefore, if desired, be made to act as a supply pipe to the turbines and other motors. Provision is also made for connecting the latter directly with the city service. The pumps and motors all discharge into the flume, and the water then passes over the weir where the volume of discharge can be measured. If the volume is not too great, it can be at once measured by passing the water into the large calibrated tanks.

The weir may be used the whole width of the flume without side contractions, but by means of suitable checks one or more side contractions can be introduced and the width of the weir diminished to any required extent, or the weir may be subdivided into two or more independent weirs. A large number of experiments have already been made to determine the co-efficient of discharge with and without side

*Extracted from a paper read before the Canadian Society of Civil Engineers.

contractions, and with different depths of water over the weir lip. The results will be given as soon as the experiments have been completed. The water may be conveyed to any one of the five tanks through an iron channel provided with properly placed manholes, and the five tanks can all be connected together by means of a 10-inch pipe running along the bottom of a deep trough next the wall, and having the

necessary valves and 6-inch branches communicating with the several tanks. The water may also be run to waste through this 10-inch pipe. In this channel and next the weir there is a flap-door with edges inclined at 45° to the vertical. The edges of the gap closed by the door are also inclined at 45° to the vertical, and the fit between the door and gap has been made as perfect as practicable. An india rubber cord is inserted in an endless groove running along the centre line of the edges, so that when the door is closed and pressed home it is absolutely water-tight. The door can be instantaneously opened and closed by means of a lever and a system of links acting as a toggle-joint, and each movement is recorded by an electrical chronograph. In any given experiment the door is opened and the water allowed to run to waste until the head over the weir lip is steady, when at a signal the door is instantaneously closed, when the water is conveyed by the channel into any or all of the tanks.

The stand-pipe for the fire-hose rises vertically at the back of the tank and extends to the full height of the building. At the base it is provided with a number of unions varying in size from six to one inch, and to these unions are attached the lines of piping for pipe-flow experiments. The position of the stand-pipe was selected so as to allow of straight lengths of more than 400 feet of pipe being used. To secure a uniform pressure a Locke Regulator has been provided, which responds, though slowly, to a variation in the pressure. A special piece of apparatus for hose testing has been placed in the south-west corner of the laboratory. It is connected by hydraulic piping with the Blake pressure pumps in the testing laboratory. A large number of tests have been made on the strength, and on the longitudinal and circumferential extensibility of different varieties of hose, which in the great majority of cases was in lengths of 50 feet. The pressure, which often exceeded 800 lbs. per square inch, was directly indicated by a standard Crosby gauge, while the time and pressure were also registered automatically by a recording gauge specially designed for this work.

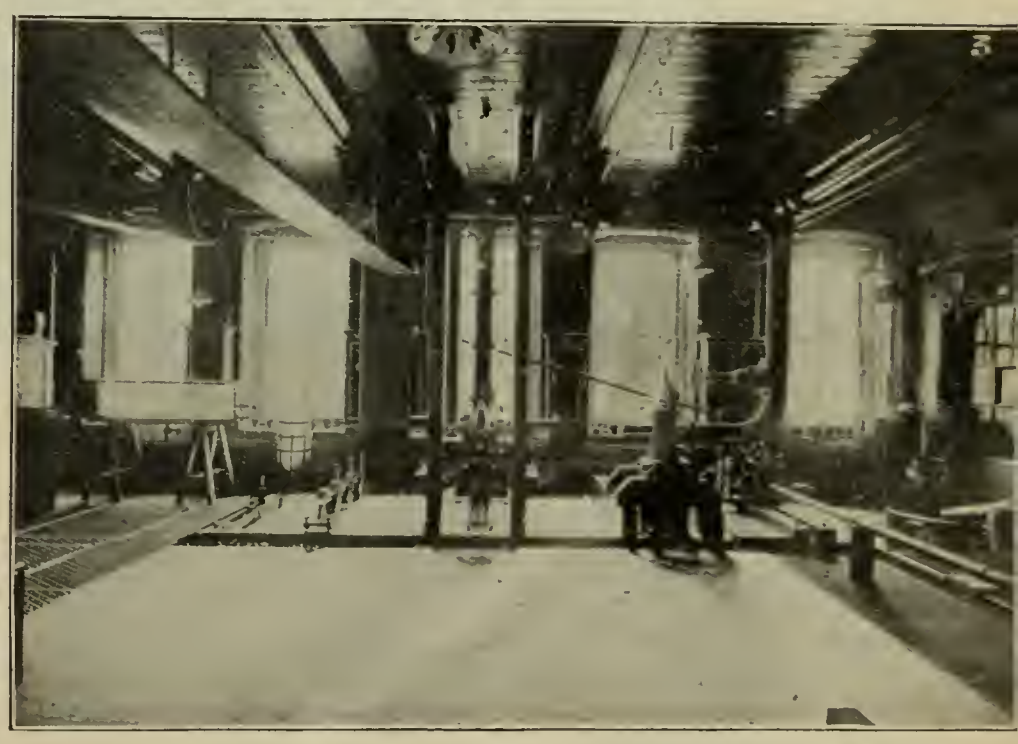
Of the remaining apparatus the following may be briefly noticed :—

A glass tank, 72 inches by 18 inches by 12 inches, with circular diaphragm chamber at one end. This serves to illustrate vortex ring motion, and also, with the aid of glass tubes with flared ends and of different diameters, the critical velocity and other stream-line phenomena. Inverted glass domes, with an orifice in the bottom, with which are demonstrated the phenomena of circular and spiral vortex motion, of the inversion of the vein, etc. A series of very carefutly made nozzles with a perfectly smooth bore, and having pressure gauge attachments at each end. Each nozzle is 36 inches in length between the gauge connections, and has a taper corresponding to a diameter, varying from 3 inches to 2¾ inches in the largest to 3 inches to ½ inch in the smallest. A series of sixty hydrostatic gauges, each with a range of 20 lbs. and embracing pressures up to 140 lbs. per square inch. The gauges are graduated to tenths of a pound, and the range of every gauge is overlapped by the two consecutive gauges. A mercury column 27 feet in height, is fixed to the north wall near the experimental tank, and in addition to this there are several small portable mercury columns, which are used in the experiments for determining the resistance to flow in small pipes due to elbows, bends, convolutions, etc. These pipes are 13 in number, have a smooth bore and are ⅜ inch in diameter. The laboratory is also supplied with a Venturi and other piston and rotary meters, a number of hook gauges, Darcy's improved Pitot tube, brass standard gallon, quart and litre measures with glass strikes, etc , etc.

There are several copper measures of capacities varying from 10 to 100 gallons. They have been carefully calibrated, and the calibrations are frequently checked. When in use they are placed upon a plane-table with adjustable feet so that a true level can be always maintained. Each of the large tanks already referred to is 6 feet by 3 feet 6 inches by 9 feet deep, and discharges into the 10-inch header through a 6-inch straightway valve. Each tank is also connected with a separate vertical 4-inch brass pipe, in which the water freely rises and falls with the water in the tank. This forms the float chamber. These tanks have been carefully calibrated, and the contents can be readily measured to within the sixteenth of a gallon. The float is attached to a vertical $\frac{3}{8}$-inch brass rod with a pointer at the upper end, indicating on a brass plate the quantity of water in a tank. A fine cord, fastened to the top of the rod, rises vertically, passes around a frictionless pulley, and carries a constant weight at the end which counter-balances the rod, etc., keeps the cord taut, and so prevents the pointer from rubbing against the plate.

The experimental tank is of cast iron, is 28 feet in height, square in section, and has a sectional area of 25 square feet. Every care was taken to make the inside surfaces of the tank walls perfectly flush, and to this end the flanges, by which the several sections were bolted together, were placed on the outside.

The impact apparatus was constructed for the purpose of determining the force with which jets from orifices, nozzles, etc., impinge upon veins of different forms and sizes. A massive cast-iron bracket, 8 feet in length, has one end securely bolted to the front of the tank, and the other supported by a vertical tie-rod from one of the oak beams in the ceiling. The upper surface is provided with accurately planed slides, which are set level about 5 feet above the orifice axis. If, from any cause, the end of the bracket farthest from the tank is found to be too high or too low, the error can be corrected by loosening or tightening the nut on the tie-rod. The balance proper is carried by a sliding frame, which can be moved horizontally into any position along the bracket by means of a rack and pinion actuated by a sprocket wheel with chain. At one end the frame has two equal arms with a common horizontal axis parallel to the bracket, and each arm has a stop on its lower surface which serves to limit the oscillation of the balance. The balance, in its mean position, consists of a main trunk



with horizontal axis rigidly connected with a vertical slotted arm and with two equal horizontal arms at one end. The common axis of the latter is horizontal and perpendicular to the axis of the main trunk. The hardened steel knife edges of the balance are 4 feet centre to centre, and rest in hardened steel Vees inserted in the ends of the sliding frame on each side of the bracket. The bottom of each Vee is in the same horizontal line (called the axis of the Vees) at right angles to the bracket. A bar with the upper portion graduated in inches and tenths has a slot in the lower portion, which is bent into a circular segment of 9½ inches radius The bar slides along the slot in the vertical arm of the balance. A radial block, with the holder into which the several vanes are screwed, moves along the slot in the circular segment, and may be clamped in any required position, the angular deviations from the vertical being shown by graduations on the segment. The centre of this segment in every case coincides with the central

point of impact on a vane, is in the vertical axis of the balance arm, and is also vertically below the axis of the Vees. Thus the jet can always be made to strike the vane both centrally and normally. The scale pan hangs from a knife-edge at one end of the horizontal arms of the balance, while to the other end is attached a fine pointer, which indicates the angular movement of the balance on a graduated arc fixed

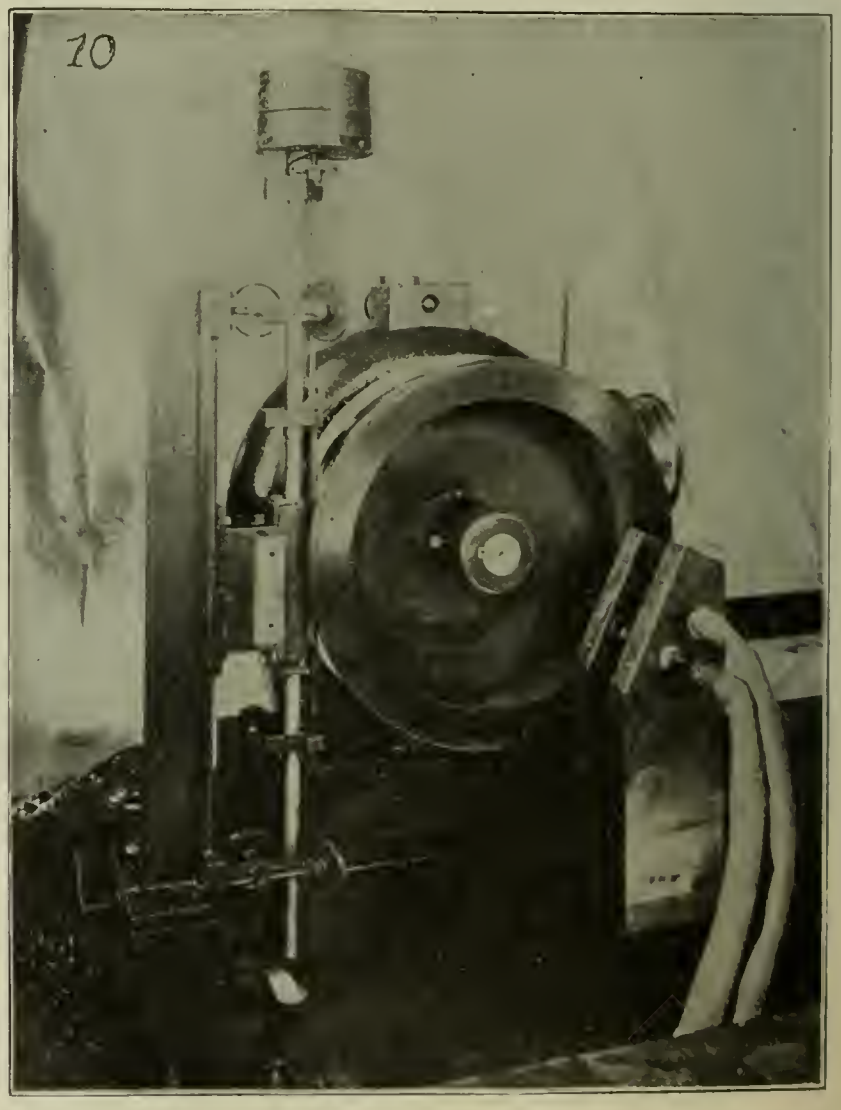
to the sliding frame. The balance is in its mid-position when the pointer is opposite the zero mark. When a vane has been secured in any given position, the preliminary adjustment of the balance is effected by moving a heavy cast-iron disc along a horizontal screw fixed into the main trunk. The sensitiveness of the balance is also increased or diminished by raising or lowering heavy weights on two vertical screws in the top of the trunk.

In motor testing it is often of importance to know the pressure of the water at certain points in the supply (or delivery) pipe, and, generally speaking, it is impracticable to employ either a mercury or a water gauge. The pressure is therefore observed by standard Bourdon gauges, of small individual range, which are frequently tested, a record being made of the errors. The method usually adopted to diminish the oscillating effect of the gauge of the fluctuation in the flow is to connect the bore of the pipe with an annular chamber by a number of small holes. In the McGill Laboratory these holes have been replaced by a continuous opening around the bore, less then .005 inch in width, with the obvious result of obtaining a better mean pressure. Similar chambers are also being used in experiments on the resistance of bends to flow. There are four sets of bends of 1 inch, 1½ inch, 2-inch and 3-inch diameter, and each set consists of 30 bends, 10 having a radius of one diameter, 10 of two diameters and 10 of four diameters. At the central cross-section of each bend, provision is also made for ascertaining the pressure, either by a mercury column or by a gauge, at the extremities of the radii to the outer and inner surfaces of the bore. The chambers for the bends are combined with union couplings, of the same bore, which allow the attached part to be swivelled through any required angle.

The speed of the motor is taken by a revolution counter and also by a tachometer. A sliding slotted sleeve at one end of main shaft of the motor can be made to engage with the spindle of the revolution counter, which can therefore be readily thrown in and out of gear at the commencement and end of a test, and the readings can be taken at leisure. The tachometer is supported on a bracket fixed to the motor frame, and is driven by a cord passing over a pulley on the motor shaft.

Besides a Halpin brake of 50 h.p. capacity, the laboratory is equipped with a friction brake which has been designed by Mr. Withycombe, the superintendent, and which can be used with wheels both of the horizontal and the vertical type It possesses many novel features of which the most important are :—That it is self-adjusting, and that a single direct weighing gives the total drag. The brake wheel is of cast-iron and finished on a lathe. The outer and inner surfaces of the rim are shrouded, the shrouding on one side being formed by the solid disc connecting the rim with the boss. A stream of water is delivered tangentially into the channel inside the wheel through a narrow rectangular mouthpiece of nearly the same width as the channel. The surplus water is carried away by a scoop of somewhat similar form but reverse in action. The tight portion of the brake band is of leather, and the slack portion consists of two strips of copper. In the mean position, each portion embraces about one-half of the circumference of the pulley, and its end is attached to a lug projecting from a rod. The lug to which the slack portion is joined is capable of sliding along the rod, and by means of a screw, can be adjusted so as to increase the slack tension as desired, and therefore to produce any required total drag. The rod in the direction of its length has a practically frictionless range of five inches, which corresponds to a variation of about 16° in the angle of band contact. The resultant force along the rod is the difference between the tight and slack tensions, and measures the drag. The force is balanced by dead weights which are placed in a tray at the top of the rod for a vertical wheel, and if the wheel is horizontal, in a scale-pan suspended by a cord which passes over a frictionless pulley and is attached to the head on the rod.

If from some cause, the band friction should increase, the drag would also increase, and there would be a corresponding movement of the rod. Thus a portion of the leather band would be unwrapped, while an equal portion of the copper band would be brought into contact. But the frictional co-efficient for leather exceeds that for copper, so that the drag would be less and would continue to diminish until it again balanced the weight. The reverse, of course, would be true, if the band-friction should diminish. The rod would move in the opposite direction, an excess of the leather band would be brought into contact and the drag would continually increase until equilibrium was again restored. Hence, within a certain range, the band will find a position of equilibrium, although the friction may vary, and the total drag will then be measured by the dead weight in the tray or in the scale-pan. If the movement of the rod should be so great that it may come against one of the stops provided to limit its action, the drag can be readjusted by means of the screw attachment. This, however,



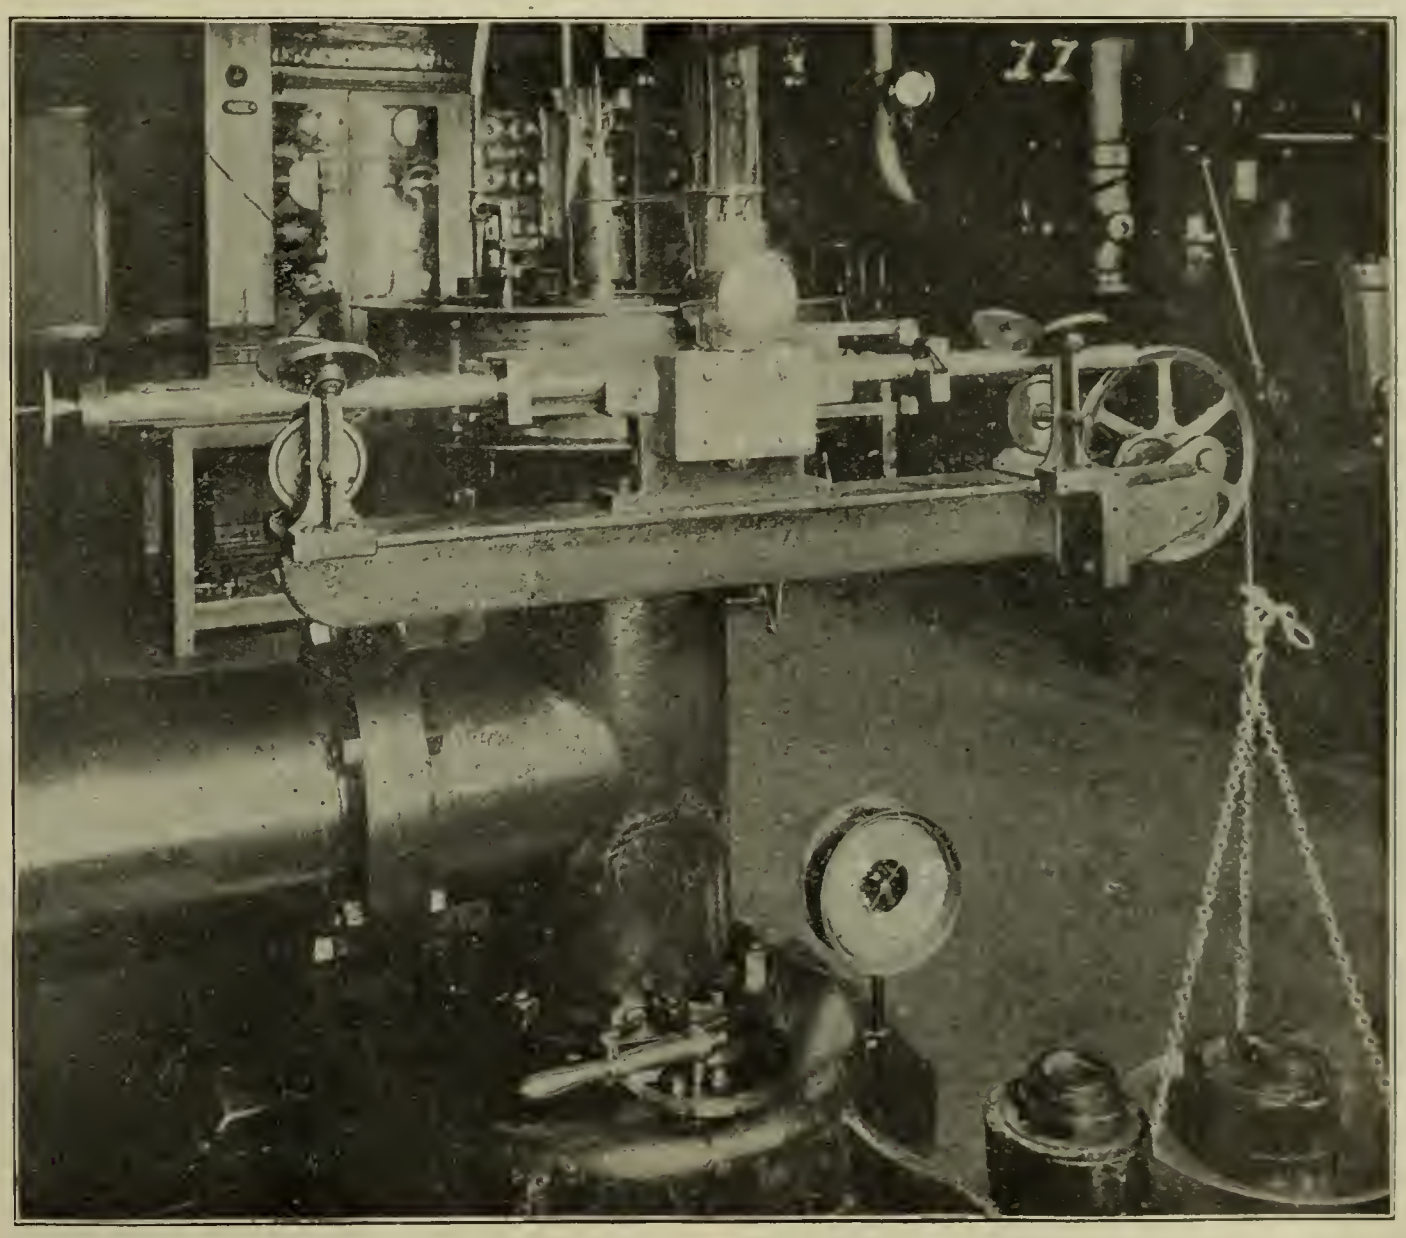
is very unlikely to happen, as the range already allowed is sufficient to admit of a large variation in the value of the co-efficient of friction. It has been found that the best results are obtained by running the wheel without any lubricant on the rim ; care should be taken to protect the rim from water or oil, which would necessarily produce a considerable variation in the frictional resistance. This brake has been in use only a few months, but in the several trials which have been made it has fully realized the expectations that had been formed of its efficiency. It has been employed in measuring directly off the jack shaft the power developed by a 6-inch turbine with vertical axis and a 16-inch Pelton wheel with horizontal axis.

The whole of the water is discharged into the flume, and passes over the weir into the large calibrated tanks. If the quantity is too great to be measured in the tanks, the water is run to waste and the discharge calculated from the normal weir formula. Co-efficients of discharge have been found for various depths over the lip, and the co-efficient for any particular depth can be very approximately determined by interpolation. The depth over the lip is obtained by means of the "depthing" apparatus, which consists of a deep girder stretching across the flume and carrying three hook gauges with Verniers which read to .001 inch.

The centrifugal pump is erected over the flume in a framework which allows it to be raised or lowered so that the heights of suction and discharge may be varied at will. For this purpose the piping is made in interchangeable lengths of 2 feet. The pump is driven by a 9-inch belt and discharges into the ceiling circuit already described. From this circuit the water is delivered into the top of the experimental tank, flows into the adjoining flume, passes over an intercepting weir for calibration and is then again conveyed along the flume to the pump. Thus, the same water can be used over and over again.

approximate maximum delivery is estimated to be 1,000 gallons per minute when the pump is running at a speed of 150 revolutions per minute against a pressure of 120 lbs per square inch. The suction valve chambers are placed directly over the calibrating tank nearest the east wall, and draw the water from this tank through two 10-inch suction pipes. Each discharge valve chamber is directly connected with a 12-inch header, which discharges into the 8-inch ceiling circuit. The water may be made to flow in almost a direct line to the point of discharge, or it may be made to pass around the three sides of a rectangle so that the effect of the additional bends and increased length of piping may be estimated. The water flows into the experimental tank at a point 20 feet above the level of the discharge valves.

One of the features of the pump is the provision made that the valves can be taken out and replaced by others of a different type. The valves at present in situ are a Riedler valve and two with groups of 36 circular disc valves of $1\frac{5}{8}$ inches diameter in each. In addition to the usual pressure gauges, tachometer and revolution counter, the pump is fitted with a specially designed continuous triple indicator apparatus, which autographically records during any given time of a trial the



The turbine is supported upon an angular flange bolted to the bottom of a cast-iron cylinder. An 8-inch tee is secured to the crown of the cylinder, and a cover with a specially designed gland is bolted to the upper flange of the tee. The jack-shaft passes through this gland, which forms an almost frictional bearing. No packing is required, as provision has been made for carrying away any slight leakage that might occur. The jack-shaft passes through a piece of pipe screwed to the bottom of the cover and extending downwards to the cylinder, so that it is protected from the impulsive effect of the inflowing water. The supply pipe is connected with the horizontal branch of the tee, and the entrance of the water is controlled by an 8-inch straight-away valve placed at some distance from the opening. The gates of the turbine, for example, one of the New American inward and downward flow type, are worked by means of a shaft extending from a pinion geared to the toothed quadrant and passing through a gland in the crown of the cylinder. The upper end of the shaft is provided with a handle and pointer, which indicates on a graduated quadrant the extent of the gate opening. Suitable pressure gauge connections have been arranged in the upper and lower parts of the cylinder. The power of the turbine is determined by the friction brake already described.

The experimental pump is of the vertical triple-throw single acting plunger type, and is driven by two 10-inch double leather belts running on 48-inch pulleys formed on the outer crank throws, or discs. The plungers are 7 inches in diameter and have an 18-inch stroke. The speed, variation and duration of the valve chamber pressure at any point of the stroke. Sight holes are provided for observing the movement of the valves and indicators for recording their lift. A special recording gauge also registers the pressure in the delivery pipe. As the pump is for experimental work, it has been made unusually heavy, its total weight being about 55,000 lbs. The plungers, valves and valve seats, all internal screws, nuts, etc., are of bronze, and weigh more than 3,700 lbs.

TORONTO AND SEWAGE DISPOSAL.

Editor CANADIAN ENGINEER:

SIR,—On March 17th, Jno. McDougall, of the Detroit Purification Company, who pushes the old system of the International Water and Sewage Purification Company, of London, England—which company has within the last two years improved its methods by making its filtering process into an intermittent, in place of a continuous flow system, thereby purifying the sewage by bacteria which require atmospheric air regularly at short periods—appeared before a special committee of the Toronto City Council and described the method of treatment, and also showed blue print drawings of the precipitating tanks and filters that they adopted. The plan of the tanks and full information we have before published in the October and November issues of 1896, and the March and May issues of 1897.

Mr. McDougall's remarks showed that his company keeps to the old methods of continuous flow both in the settling tanks and filters, while

his principals in England have been compelled by the sanitary inspectors to march with the times and adopt the intermediate system. This system is about the most expensive one that can be adopted, and includes some intricate sludge machinery that soon gets out of order and is really unnecessary because the sludge will come away better without it. The ferrozone precipitant necessary to this system would be a heavy, constant and useless expense. The polarite used for the filtrate is said to cost $30 per ton, and it is now a recognized fact that screenings of coal that only cost $2 50 per ton, are far more efficient and lasting when used as a filtrate, standing ahead of every other material except charcoal made from wood or towns' garbage. On page 326 of the March, 1897, issue of THE CANADIAN ENGINEER, there is a table showing the cost of sewage disposal in twenty towns of England. The last one, Swinton, is worked on Mr. McDougall's plan. Of this town, Mr. McDougall's company states that there is 16,000 population, the average daily sewage is 300,000 gallons, that they can give their sludge away, that their tank capacity is 240,000 gallons, that the plant cost $30,000; it costs $3,000 each year to manage it and pay for ferrozone. The population of Toronto is over twelve times that of Swinton, and Dr. Sheard said that there will be a much larger quantity of sewage per head discharged in Toronto than in British towns. In that case our sewage works may cost about $360,000 for plant, and $36,000 per year after, and then we might have to provide sludge presses and furnaces to burn the sludge cakes in addition.

Mr. McDougall was ably supported in showing the advantages of his company's system by Mr. Warner, who had come all the way from Nottingham, England. He is the patentee of the Low Temperature, Slow Burning and Natural Draught Garbage Destructor, which has been fully described in page 286 of the last February issue of THE CANADIAN ENGINEER. When answering a straight question put by Ald. Lamb, Mr. Warner stated that the Toronto garbage destructors were similar to the ones he built twenty years ago, and it will be admitted that the high temperature fume consuming, quick burning and heat raising destructors are five years ahead of the low temperature ones, so that Toronto must be a quarter of a century behind similar towns in this line of sanitary appliances. The saying of the late Benjamin Franklin, viz., "Be careful that you do not pay too much for your whistle," is applicable when a sewage scheme is under construction.

EXPERT.

Toronto, May 15th.

CEMENT IN ONTARIO.

During 1897 the cement industry in Ontario has made satisfactory progress, as shown in the report of the Bureau of Mines. Both the natural rock and Portland cements are showing a large increase of production, and manufacturers are establishing a good reputation for the qualities of the cements they are putting on the market. The increase, however, is not shown in the number of establishments, which are two less now than four years ago; but in number of men employed and amount of wages paid for labor, in quantity of cements produced and in their value there is a gratifying evidence of progress. The number of men employed in these four years has increased from 168 to 231, the wages paid for labor from $44,878 to $89,060, the quantity of cement manufactured from 85,903 barrels to 181,495 barrels, and the value of the cement from $109,834 to $246,425. The greatest increase, however has taken place in the production of Portland cement, which has gone up from 30,580 barrels to 96,825, while the natural rock cement has only increased from 55,323 barrels to 84,670. In value natural rock cement shows an increase of $27,349, while the Portland cement shows an increase of $109,242. This, no doubt, is largely, if not chiefly, owing to the growing interest in the building of good roads in our towns and cities.

All of the natural rock or hydraulic cement works are now situated along the Niagara escarpment, extending from Queenston, near the Niagara River, to Limehouse, on the main line of the Grand Trunk Railway.

One of the Portland cement works is situated at Shallow Lake in Grey county, where the business is carried on by the Owen Sound Portland Cement Company. New machinery was added during the past year, and new buildings and more kilns are now in course of erection which, when completed early this summer, will bring the output up to over 300 barrels per day. The product of the works is known as the Samson brand, and the manager states that not a single complaint was received last year regarding the quality of the material put upon the market. Both the marl and the clay used in the manufacture of cement at these works are obtained from the bed of Shallow Lake.

The works of the Rathbun Company at Napanee Mills were also enlarged last year, and they have now an estimated capacity of about 350 barrels per day. The plant embraces the latest and best developments in Portland cement making, and is constructed with a view to produce material of very uniform quality. The clay and marl are mixed in proportions carefully regulated by chemical analysis, and the slurry is so finely reduced in the mixing mills that it will all pass through a seive of 100-mesh, or 10,000 holes per square inch. Two new burning kilns were erected last year, making three in all; they are of the continuous type, and produce a very uniform well burnt clinker. In the grinding mill the clinkers are ground to an extremely fine powder, and, so finished, it is conveyed to bins in a new storehouse, which has a capacity of 50,000 barrels. The Rathbun Company's cement is known as the Star brand, but they are now producing a quality called the Silica Portland. The marl for the works is drawn from an extensive deposit on the line of the Bay of Quinte Railway, and the clay from a property adjoining the works.

During the fiscal year ending June 30th, 1897, Canada imported 210,871 barrels of Portland cement, valued in the Trade Returns at $252,587; so there is yet considerable room for expansion in the industry at home.

PNEUMATIC GRAIN-HANDLING MACHINERY.*

BY FREDERIC ELIOT DUCKHAM.

The grain trade of the world has been steadily increasing, and the bulk of the cargoes and the tonnage of the vessels is now so great that the time consumed in unloading and the cost of keeping the vessel in docks are very serious considerations. To deal with such a large amount of trade, the old method of working by hand has been gradually replaced by the use of various machinery, such as the endless band, carrying a number of comparatively small buckets travelling at a speed of about 100 feet per minute in an enclosed trunk, and which has for some years been in use in America, in Liverpool and elsewhere; but where the cargoes to be discharged are of a mixed character, e.g., general goods and packages in the 'tween decks, and grain in bulk in the lower hold, it has been found more convenient to use hydraulic cranes with self-opening and closing grabs, or buckets filled by hand and self-discharging, or other contrivances with which to lift the grain, but which can at any time be exchanged for slings or hooks for the discharge of the ordinary merchandise. In all these methods, however, it is only possible to reach such of the grain as is within the area of the hatch; the other portion, which may extend 100 ft. or more fore or aft, has to be trimmed to the hatch by manual labor or by the so-called steam shovel. Grain is often brought in bunkers and other confined spaces in which it is not practicable to employ either of these machines, and so the grain in these places has to be filled into sacks and unloaded by manual labor. But when one has to deal with present-day vessels of 10,000 tons capacity, representing a capital expenditure of £70,000, and a debit of £70 for each day in dock, it is of very great importance to increase by every possible means the speed with which their cargoes can be loaded or unloaded. In this direction the skill of the naval architect has been shown, and must still continue to be shown, in so designing the vessels that they may not only be safe and otherwise satisfactory for navigation, but present the greatest facilities obtainable for the receipt and delivery of their cargoes.

It is also of importance that such improvements be made in the machinery employed that the greatest amount of work may be done in the shortest time and at the lowest cost, with safety. It was with such requirements in view that the author directed his attention to the employment of air for elevating and conveying bulk grain. There was no originality in this idea—air under vacuum, as well as under pressure, had from time to time been tried in this country and abroad for this purpose; but several difficulties presented themselves and prevented the successful operation of the machinery. Prominent among these were the difficulties of sucking or forcing grain in bulk through pipes, of getting the grain out of any vacuum chamber into which it had been drawn, and of separating the grain and its dust from the air which had conveyed it. The author feels that he need not give in uninteresting detail the various steps by which these and other difficulties were overcome, but would at once refer to two types of pneumatic elevators now in successful operation. One of these is employed for the discharge of sea-going vessels overside into barges at the Millwall Docks and the Albert Docks, London, Bremerhaven, Hamburg, etc. In these the machinery is afloat in a hull of, say, 80 feet by 24 feet by 10 feet; in each the machinery under deck consists of a compound engine connected direct with air-exhausting pumps capable of producing and maintaining a partial vacuum 15 inches of mercury in a tank into which, say, 5,000 feet of air, under atmospheric conditions, is being admitted per minute. The boilers are of the ordinary marine type; the engines are surface-condensing. On the deck of the craft, one, or in some cases, two or three towers are erected each to support a vacuum tank, which acts as a grain receiver, and is say, 10 feet in diameter by 16 feet high. This tank is coned at the

* From a paper read before the Institution of Naval Architects.

bottom, and has connections for two or three pipes through which the grain is drawn with the current of air from the hold of the ship. An automatic air-lock is fitted through which the grain discharges itself from the tank into the hopper of the weighing machines, and after weighing, it flows into the barge in bulk, or it may be sacked and delivered in that way. The men required for the discharge of, say, 100 tons per hour, are an engineer, a stoker, one man to each of the pipes, a leading hand, and three others for moving barges and general work. The coal consumption is about 5 cwt. per hour. This is heavy compared with the coal consumed by the ordinary bucket elevator, but as this pneumatic machine effects a direct saving of the cost of trimming the grain to the hatchway, the comparatively greater coal consumption sinks into insignificance. In fact, the whole operation of discharging is often less than what would have been the cost of trimming alone.

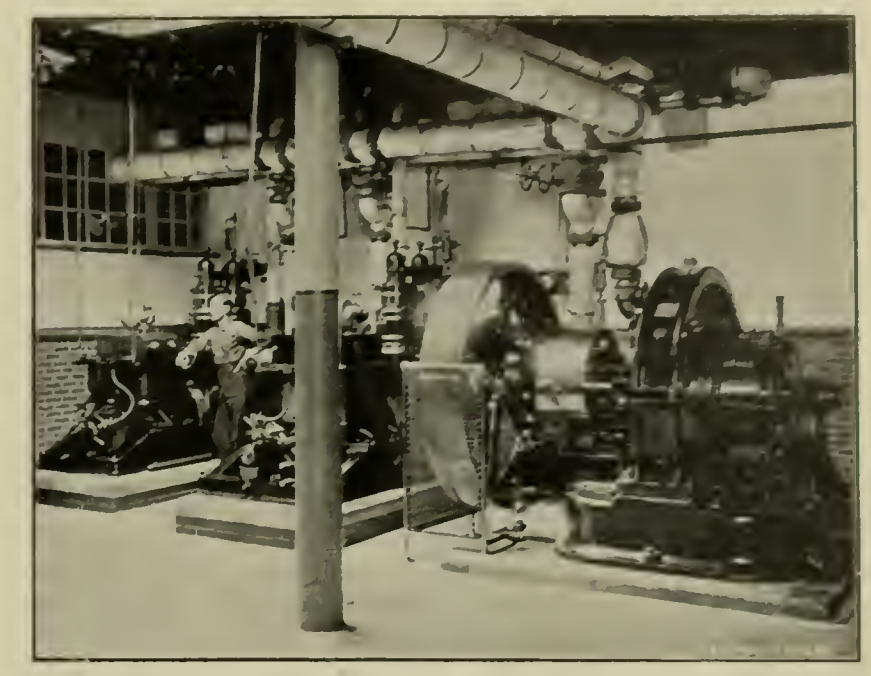
The pneumatic machine has moreover other advantages; it is worked in all weathers; it not infrequently happens that the pneumatic grain elevators are the only ship-discharging appliances at work on a wet day on the Thames. In addition to this important saving of the ship's time, it is also to be noted that the suction pipes, being suspended from the elevator derrick, can be lowered into the ship's hatchway and the discharge commenced within a few minutes of the machine being brought alongside. There is none of the usual loss of grain in handling, as the cargoes are conveyed within closed conduits from the discharging ship into the receiving barge, and the grain is, moreover, improved by such intimate contact with the conveying air. This is specially so when the grain is heated and out of condition. The suction pipes, which are semi-flexible, can be taken by any tortuous route into the bunkers or other confined spaces, and the grain can be drawn out therefrom almost as readily as from the ship's hold. There is obviously an entire absence of the dangers to life and limb that are inseparable from the ordinary lifting machinery. The elevator vessels are fitted with steam capstans to assist in moving themselves, as well as the barges that come alongside for loading.

IMPROVEMENTS IN THE ELECTRICAL PLANT AT McGILL UNIVERSITY.

The university has again to thank W. C. McDonald for generously defraying the cost of extensive alterations and additions to the light and power station, connected with the faculty of applied science. The equipment is now installed in a handsomely finished,

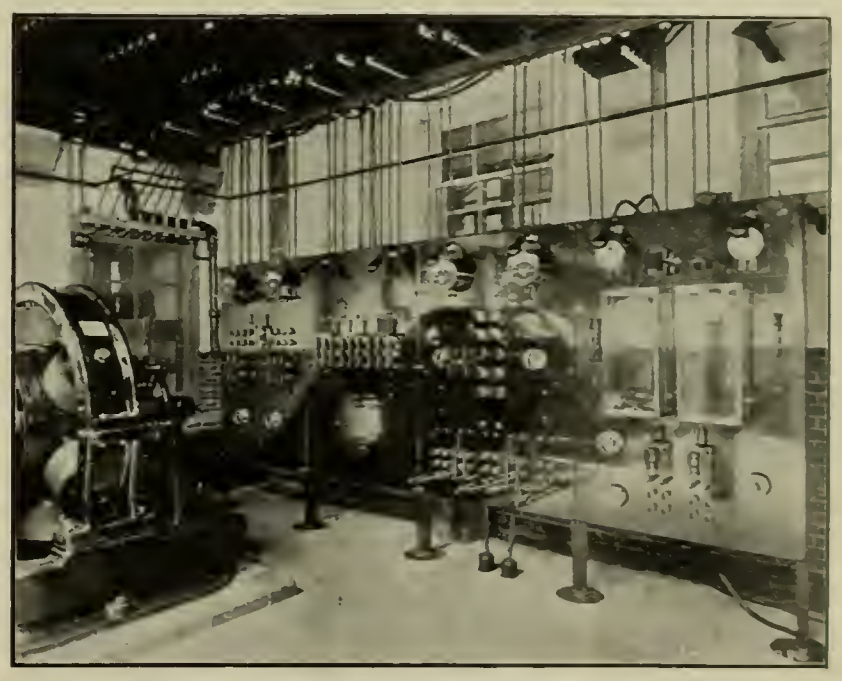
L. Herdt, B.A.Sc., E.E., Lecturer in Electrical Engineering, McGill University.

well-lighted room, and consists of a 30 k.w. Edison-Hopkinson dynamo, and a 30 k.w. Siemens dynamo, each driven by a Willans high speed engine; the dynamos are on the shaft of the engine, making what is known as direct connected units. These two machines are capable of lighting the different buildings of the university, supplying current for more than 3,000 lights. The dynamos are run in series on the three-wire system, or if the load is light, one can run on the two-wire system. In addition there are installed a 100 h.p. Goldie & McCulloch engine, directly coupled to a 75 k.w. General Electric dynamo. This machine is set apart for power purposes, the motors in the building averaging about 110 h.p. It may be also used for lighting purposes when the demand exceeds the capacity of the two former dynamos. The switchboard is made of dark slate in panel form, and it is said to be one of the finest in Canada. The lighting of the buildings at night is effected by the help of accumulators. The accumulator room, standing beside the dynamo room, possesses two batteries of Crompton-Howell storage cells, of a united capacity of 800 ampere hours. These batteries would discourage the antagonism of the adversaries of accumulators, for they are subjected to all kinds of discharges, and after a usage of over six years have an all-round efficiency of 72 per cent. An ingenious arrangement, devised by Louis A. Herdt, lecturer in electrical engineering, enables one battery to be



Electrical Plant—McGill University.

taken out of circuit, and the other one to be put in circuit during the night, as soon as one of the batteries shows signs of being discharged. The plan of the new dynamo room is such as to permit of the plant being extended so as to light any further buildings that may be erected or any of the existing buildings, such as the Library and Museum, which are at present lighted from other sources.



The Switch Board—Electrical Plant at McGill University

To increase the educational advantages of the mechanical engineering department especially, two of the battery of four Babcock & Wilcox boilers have been replaced by a boiler of the Lancashire type, and one of the Locomotive type. Both the new boilers were made in Canada, one by John Macdougall, the Caledonia Iron Works, Montreal, and the other by the Robb Engineering Co., Limited, Amherst, Nova Scotia.

SEWAGE DISPOSAL BY SUBSOIL IRRIGATION.*

By E. Mohun, M. Can. Soc. C.E.

In October, 1894, the author received instructions from the Hon. the Chief Commissioner of Lands and Works to devise some means for disposing of the sewage of Government House, Victoria, B.C., and though the work undertaken is but on a small scale, he trusts that it may prove of interest. It was found that the sewage of the building had been disposed of by the simple expedient of running a 6-inch pipe across a field and discharging into the street ditch, thereby creating an intolerable nuisance. The sewerage system of the city had not been extended in that direction, and to make connection with the nearest point it would have been necessary to construct a sewer about 3,600 feet long, nearly all the trenching for which would have been through solid rock. The contour of the ground being adapted to the purpose, it was decided to dispose of the sewage by subsoil irrigation. Reference to the books of the water department showed that the house consumption as taken by metre was remarkably small, frequently not exceeding 300 gallons a day.

* A paper read before the Canadian Society of Civil Engineers.

The only pipes available were 6-inch circular drain pipes, T pipes, and 3-inch circular drain tiles. At a convenient point in the field the old sewer was cut, and an automatic flush tank built, from which the sewage passed down a tight 6-inch conductor to the inlet ends of the 3-inch drain tiles.

In laying the drain tiles the following method was adopted: Contour lines having been set out with the level and the trench cut along them, bricks were laid with a carpenter's level 8 feet long, so as to form level and solid bearings beneath the ends of the drain tiles laid upon them.

The connection with the six-inch conductors was made by turning down a 4 × 6 T, and making connection with the drain tiles by means of a galvanized iron taper. The ends of all the drain tiles are provided with air vents, made by galvanized iron, and connected with the drain by quarter bends. The area irrigated is nearly one acre, and it has not been found necessary to underdrain, as the whole of the discharge appears to be absorbed by the earth. The total length of the drain tiles is 1,463 feet, and from their upper surfaces are from 10 to 12 inches below the ground surface. Their alignment is marked on the ground by lettered stakes. The flush tank is provided with an L screen, ¼ mesh, divided into three compartments by weirs; into the first the sewage discharges directly through the old pipe; as the screen becomes clogged with paper it overflows into the second compartment and similarly into the third. It has not been found necessary for the scavenger to clear the screen more often than once in six weeks, though for other reasons it is done once a month. No offensive smell can be detected either at the flush tank or on the lines of pipes, nor is there any indication of excrement sodden soil. The gardener states that the ground never before produced vegetables equal to those grown since the sewage system was installed.

The ground to the north-west is considerably higher than the field and garden, and is very rocky. Shortly after the completion of the work, snow fell, and within a few hours a rapid thaw took place accompanied by heavy rain, the water actually running over the surface in a sheet. Under the circumstances the tile drains became surcharged, and when the rush from the flush tank took place it can hardly be considered wonderful if three or four of the tiles were broken. They were of course easily replaced, and a similar occurrence guarded against by cutting an intercepting ditch across the field to lead the surface water into the street ditch. An object sought to be arrived at was to so proportion the tank that each discharge would fill all the drains, practically, simultaneously.

The cost of labor was high, a good deal of rock being met with in laying six-inch conductor. The work was performed by day labor under the author's instructions, and its cost was: Material, $255.68: labor, engineering, etc., $244.30; total, $499.98.

THE POSSIBILITIES FOR SMELTING IN BRITISH COLUMBIA.*

BY R. A. HEDLEY, NELSON, B.C.

My knowledge of the country and my study of its ores enables me to make certain statements, which I feel myself qualified to make somewhat authoritatively. My data, however, are insufficient to handle the subject very thoroughly.

Lead smelting offers some difficulties for any plant possible with present production of the lead producing mines. First, its capacity would not warrant the erection of a complete refinery, and without it lead must be refined in the United States, paying a duty of two cents per pound, while lead in ore pays but 1½ cents per pound. As the bulk of the lead ore shipped is of high grade (over 65 per cent. lead) this renders it difficult to compete with the smelters of the United States, as the difference in freight paid is but slight. To illustrate this point, let us suppose that ore is shipped to the United States carrying 65 per cent. lead. Assume freight at $8 per ton, duty is $19 50, making $27.50. Smelted here, bullion shipped at same freight rate will pay $5 20 and duty will be $26, making $31.20. It would seem, then, better to leave a high grade lead ore severely alone, unless the product can be disposed of to better advantage than by refining in the United States, paying duty on lead. Suppose a 40 per cent. lead ore shipped; it will pay freight, $8, and duty, $12, making $20. Smelted in this country and bullion shipped, freight will be $3.20 and duty on lead $16, making $19 20.

This is in favor of smelting as regards these two items of cost. Now the ores carrying 40 per cent. lead or less are as yet but a small item, and generally speaking carry a high percentage of zinc, or else the gangue is a barren silica, making fluxing costly.

The production of the whole Slocan district may be roughly stated at 100 tons per day, of which 60 per cent. is of high grade, over 65 per cent. lead, and 25 per cent. at least, carries fully 15 per cent. zinc. The question of flux is an important one in considering the treatment of these ores. Lime is very abundant, of good quality and cheap, but iron oxide of fair purity does not occur, and metallic iron as scrap is procurable in but limited quantity at the rate of $15 per ton. The ores of Rossland district have been spoken of as suitable for fluxing lead ores, but that is a very questionable point. An average Rossland ore will carry excess silica, and no little arsenic, and they strike me as an expensive flux when the cost of roasting is considered. Also the difficulty of making a good roast cuts some figure in the cost of treatment. A complete roast on a mixture of galena and pyrites, enables one to charge a certain proportion of raw galena ore, a manifest saving. Until recently, I was firmly convinced that a blast furnace matting plant would handle the ores of Rossland camp very economically and to great advantage. I still believe so, though I consider the difficulties are not few.

I have no definite information regarding the treatment of Le Roi ore at the Trail smelter. Would like to be able to state to what degree of concentration they attain, and what proportion of calcined ore they use on the charge. Having analyzed samples from many of the mines, I am of the opinion that, given an assortment of ores from different mines, matte smelting can be successfully and economically carried on. The consumption of fuel and flux should be kept very low, and as these two items form by far the major portion of the cost of first concentration, it is of importance to determine whether 10 or 15 per cent. is necessary. A year ago I was told that they were using but 10 per cent. of coke, and I analyzed a piece of slag produced without extraneous flux, finding:—

Silica	49.2 p.c.	Gold .045 ozs. per ton.
Ferrous oxide	23.2 p.c.	
Alumina	14.9 p.c.	
Lime	5.7 p.c.	
Magnesia	5.4 p.c.	

It would be very interesting and instructive to see pyritic smelting thoroughly tested on these ores, with a well adapted plant. It may be said that pyritic smelting has never yet proven a success, but it has never yet had a fair trial. In Newfoundland, it has been stated that purely pyritic smelting was successfully carried on, but the ore treated, if I understand aright, carried very little slag forming material, and therefore, the concentration was low. Professor James Douglas made a trip expressly to see that plant in operation. Robert Sticht wrote at length on the subject, and described the operations of plants at Boulder, Kokomo and Toston, stating that there were obvious reasons why they were not successful, either through faulty plant or ores unsuitable.

As yet we do not know what the Rossland mines are capable of producing. Wild statements have been made on this head, but I believe that a 500-ton plant, erected at such a point and run so economically that it could make a smelting rate of $7 per ton f.o.b., Rossland, would soon have to increase its capacity. If these ores will smelt with a concentration of 10 to 1, using 12½ per cent. coke and 10 per cent. flux (limestone), that figure will leave a profit to the smelter. Speaking of possibilities, however, I consider that they are far greater in the Boundary Creek district. There, the variety is greater, and a perfectly self-fluxing ore is obtainable. I do not pretend to say that there is an abundance of ore of such grade as to maintain a large plant but I do say that there is every indication that such will prove to be the case. Once transportation is had, development will be pushed and plants will follow. Ores will be treated, both by direct smelting for matte and by previous concentration. There are very clean ores of mixed pyrites, chiefly pyrite and chalcopyrite, that will carry 8 to 12 per cent. copper and low silica; others of low pyrites and gangue, that will form an excellent slag.

Should the coal, on development, prove to be of good coking quality and in sufficient quantity, a plant with large capacity will treat ore as cheaply as anywhere on the continent. Even bringing in coke at a cost of $12 per ton laid down, I have no hesitation in stating that a 500-ton plant (two furnaces) using steam power, will smelt at a cost not to exceed $2.75 per ton of ore. This of course will produce matte the grade of which will depend on the degree of concentration and the percentage of copper in the ore.

In order to get at the margin on treating a ton of ore, let us assume certain values, and figure the cost by shipping matte, and also converting to copper, and shipping for electrolytic treatment, assume:

4 p.c. copper, at 10c.	$ 8 00	
4 dwts. gold, at $1	4 00	
4 ozs. silver, at 50c.	2 00	
		$14 00

Shipping matte: 40 p c. copper, conc. 10 into 1.

Freight to New York	$18 00
Deduction: 3½c. per lb. copper	28 00
5 p.c. of silver	1 00
	$47 00

* A paper read before the Federated Canadian Mining Institute.

Representing 10 tons of ore, or per ton	$ 4 70	
Blast furnace treatment, per ton	2 75	
Losses, say 7½ p.c. (excessive)	1 00	
		$ 8 50
Leaving a margin to miner on $14 ore		$5 50
Or converting 40 p.c. matte to metallic copper.		
Roasting and reverberatory furnace work, per ton of copper	$30 00	
Marketing one ton of copper	40 00	
	$70 00	
Representing 25 tons of ore, per ton	$2 80	
Blast furnace treatment	2 75	
Losses on treatment, say 10 p.c. (excessive)	1 40	
	$6 95	
Leaving a profit to miner on $14 ore		$7 05

You will observe that for the purpose of facilitating these calculations, I have taken my copper value at 10c. per pound. It is customary to figure at $1 per unit, or 5c. per pound in ores, which would make this a ten dollar ore. That there is every indication that such grade of ore will be developed in enormous quantity, I am sure most mining men familar with the country will agree. With East Kootenay I am not familiar, but I believe that the range between Kootenay Lake and Fort Steele will produce ores that after concentration will materially assist smelting operations in the country. West again of Boundary Creek, in the Okanagan country, I have seen evidence of ores in veins of unusual size, that will yield handsomely. The coast too, if report be true, has its ores of character suitable for smelting, and exceptionally situated for economical treatment.

My figure on converting 40 per cent. matte to copper and marketing that, seems abnormally high, but it is based on roasting in the hearth furnace by expensive hand labor, and can be greatly reduced by automatic machinery. The New York market being the best, necessitates a high freight, and if all values are paid for they must charge a good treatment rate.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports of interest to the metal trade from Great Britain during April and the four months ending April, 1897, 1898:—

	Month of April.		Four months ending April.	
	1897.	1898.	1897.	1898.
Hardware and cutlery	£5,899	£2,694	£17,917	£8,112
Pig iron	.. ..	2,683	455	5,224
Bar, etc.	858	1,682	3,889	3,967
Railroad	9,504	50	13,351	6,972
Hoops, sheets, etc.	4,608	1,817	11,009	5,470
Galvanized sheets	6,182	9,522	12,023	14,071
Tin plates	10,778	14,996	72,320	40,545
Cast, wrought, etc., iron	4,081	4,117	11,085	10,250
Old (for re-manufacture)	.. ..	495	572	898
Steel	4,752	3,486	14,987	19,421
Lead	712	1,602	2,782	4,305
Tin, unwrought	1,872	2,454	7,316	5,930
Alkali	3,667	6,042	8,189	11,558
Cement	1,110	3,503	2,953	5,491

CANADIAN ELECTRICAL ASSOCIATION.

The following is the programme of the convention of the Canadian Electrical Association, to be held at the Windsor Hotel, Montreal, this month:

BUSINESS PROGRAMME.

Tuesday, June 28th.—9.30 a.m.—Meeting of Executive Committee. 10 00 a.m.—Opening of the first session in Convention Hall, Windsor Hotel; President's address; reading minutes of last meeting; secretary-treasurer's report; reports of committees and general business. 2.00 p.m.—General business; presentation of papers; discussion.

Wednesday, June 29th.—9.00 a.m.—Consideration of reports of committees; election of standing committees; selection of place and time of next meeting; general business; presentation of papers; discussion.

Thursday, June 30th—9.30 a.m.—Election of officers.

LIST OF PAPERS.

"How to Overcome Some of the Difficulties Encountered by Central Station Men," A. A. Wright, Renfrew, Ont. (1) "The Unconscious Ownership of an Important Key"—(A Plea for the Introduction of Goods Traffic on our Suburban Tramways); (2) "The Quimby Electric Screw Pump," W. T. Bonner, Montreal. "Experiences of an Inspector," Dr. J. K. Johnstone, Inspector of Electric Light, Toronto. "The Electric Current in the Rainy River Gold Mines," W. W. Hopkins, B.Sc., C.E., etc. "The Importance of Proper Methods of Illumination," F. A. Bowman, M.A., B.E., New Glasgow, N.S. "Economics in the Boiler Room," James Milne, Toronto. P. G. Gossler, Montreal, is also expected to read a paper.

SOCIAL FEATURES.

Tuesday, June 28th.—7.30 p.m.—Trip around Mount Royal by special Park and Island cars, afterwards ascending Incline Railway to lookout on mountain to view the city under illumination.

Wednesday, June 29th.—1.00 p.m.—Visit to (1) Bell Telephone Company's new building; (2) Street Railway Company's power house, (3) power house and works of the Lachine Rapids Hydraulic and Land Company, returning to city at 7.30 p.m. 9.00 p.m.—Annual association banquet at Windsor Hotel.

Thursday, June 30th.—11.00 a.m.—Visit to McGill University. 1.30 p.m.—Visit to Royal Electric Company's lighting station and factory, then by special G.T. train to visit the works of the Chambly Manufacturing Company at Chambly.

FIRES OF THE MONTH.

May 1st—S. Buyant's sawmill in Tecumseth, Ont., together with 50,000 shingles. No insurance.——May 4th—The factory and manager's house of the Truro Condensed Milk and Canning Co., Truro, N.S. Loss $55,000; insurance on stock and buildings $35,000.——May 7th—One of the Canadian Gold Field Co.'s buildings at Deloro, Ont. Damages, $75,000; insurance, $41,000.——May 8th—Premises formerly occupied by Ontario Pump Co., Cecil st., Toronto, destroyed. ——May 10th—J. H. Connor's washing machine factory, Sussex st., Ottawa. Loss about $10,000.——May 17th—McBuril's furniture factory at Moosomin, N.W T. The loss on the furniture factory is $5,000; no insurance.——May 25th—The Thornbury, Ont., woolen mills, completely destroyed; supposed to be incendiary; insured for $5,000.

LITERARY NOTES.

There has just been published the second edition, revised and much enlarged, of "Gas, Gasoline and Oil Engines," by Gardner D Hiscox, M.E. This is a book designed for the general information of every one interested in this new and popular motive power, and its adaptation to the increasing demand for a cheap and easily managed motor requiring no licensed engineer. The book treats of the theory and practice of gas, gasoline aud oil engines, as designed and manufactured in the United States. It also contains chapters on horseless vehicles, electric lighting, marine propulsion, etc. The following are the subjects discussed:—History of the system, theory of the gas and gasoline engine, utilization of heat and efficiency in gas engines, heat efficiencies, ratarded combustion and wall-cooling, causes of loss and inefficiency in explosive motors; economy of the gas engine for electric lighting; the material of power in explosive engines, gas, petroleum products and acetylene gas; carburetters, and vapor gas for explosive motors; cylinder capacity of gas and gasoline engines, mufflers on gas engines; governors and valve gear; igniters and exploders, hot tube and electric; cylinder lubrication; management of explosive motors; measurement of power by pony brakes, dynamometers and indicators; measurement of speed, the indicator and its work; vibrations of buildings and floors by the running of explosive motors; explosive engine testing; various types of gas and oil engines, marine and vehicle motors; United States patents on gas, gasoline and oil engines, and their adjuncts—1875 to 1897 inclusive; list of the manufacturers of gas, gasoline and oil engines in the United States, with their addresses.

"The Making of the Canadian West," is the title of a new contribution to Canadian history, by the Rev. R. G. MacBeth, M.A. This is the second appearance of the author before the Canadian reading public, and his pursuit of historical work is amply justified by the warm reception given to his first effort recently published under the title of the "Selkirk Settlers in Real Life." This was a description of the mode of life and surroundings of the early settlers in the region now known as the Province of Manitoba, and the story told by one who lived among them, was so life-like and charming that the reader longed to know more of the leading actors in this interesting drama of colonization. Hence the present book, which gives graphic sketches of the leading men who figured in the political and social life of the Selkirk settlement. To use the words of the author in his preface, he has simply gone back and lived through the past again, seeing the faces and hearing the voices of other days, and what he has seen he has written. The result is a most valuable contribution to Canadian history, and the work is embellished with portraits of some ninety individuals, more or less prominently associated with affairs in the North-West. The author's style is easy and unaffected, and his sketches have a life and force derived from personal experience and

observation. The work is dedicated to Lord Strathcona, whose portrait appears as a frontispiece. The publisher is William Briggs, Toronto, a name which is invariably associated with good typography. We warmly commend this excellent book.

"The Pioneers of the Klondyke," which is an account of two years' police service in the Yukon before the country became so well known as it is now, is narrated by M. H. E. Hayne, of the North-West Mounted Police, and written by H. West Taylor. The illustrations, which are numerous, are from photographs taken on the spot by the narrator. The typography is excellent, and the whole volume is worthy of the publishers, Sampson Low, Marston & Co., London, England.

The Engineering Society of the School of Practical Science, Toronto, has issued its annual volume of papers read before the society during the year. Among the contributors are . A. W. Campbell, C.E.; P. H. Bryce, M.A., M.D.; W. M. Minty, B.A.Sc.; L. B. Stewart, D.T.S., and others.

We have before us proofs of a paper read before the Society of Arts, London, England, by Edwin O. Sachs, on "Stage Mechanism," which gives a valuable insight into some of the underlying principles of this most necessary adjunct of the mimic art.

The Rand Agency, Ltd., Johannesburg, S.A.R., has sent us the list of members and associates of the Chemical and Metallurgical Society of South Africa.

Industrial Notes.

Clinton, Ont., will probably buy a steam road roller at an early date.

Ottawa city council has passed plans for main drainage system to cost $414,000.

Berlin, Ont., has passed a by-law to buy the waterworks from the local company.

Craig Street, Montreal, is to be repaved with scoria blocks at a cost of $73,500.

The Gartshore-Thomson Pipe and Foundry Co., Ltd., has increased its capital to $60,000.

Wm. Stokes, Amherstburg, Ont., proposes to establish a cold storage plant in Windsor, Ont.

The Diamond Glass Co., Ltd., is applying for power to increase its capital to $1,000,000.

The Brompton (Que.), Bridge Co. is about to build a new bridge with iron superstructure.

The Bushnell Oil Company is enlarging the Sarnia refinery so as to almost double its capacity.

The House of Industry, Bradford, Ont., will have two wings added this summer, at a cost of $13,000.

A great deal of permanent pavement will be laid in Guelph, Ont., this summer, chiefly cement sidewalks.

The Canadian Brewing Company, Montreal, is installing a new steam plant using the Kingsley water tube boilers.

Peterboro will soon vote on a by-law authorizing the issuing of debentures for the purchase of a steam road roller.

A flood-prevention dyke is proposed by the city engineer of Brantford, Ont., T. Harry Jones, C.E., to cost $47,583.

The Bennett & Wright Co., Ltd., Toronto, is to put in the plumbing and sewage of the House of Industry, Bradford, Ont.

A. N. Bishop, Annapolis, N.S., is enlarging his sawmill, and has bought an engine and boiler from the Goldie and McCulloch Co., Galt, Ontario.

The McEachren Heating and Ventilating Co., Galt, Ont., has placed an order with the Jenckes Machine Co., Sherbrooke, Que., for a Dake engine.

The Western Loan and Trust Co., Montreal, is installing a new heating system in its building, using the Kingsley water tube boiler. David Ogilvy is the architect.

The MacGregor-Gourlay Company, Galt, Ont., has completed the purchase of the London, Ont., Machine Tool Company's business, and will transfer the business to Galt.

J. R. Booth, president of the Ottawa, Arnprior and Parry Sound Railway, has stated that he will not, at present, build a large flour mill at the Chaudiere, as had been reported.

The Consumers' Gas Co., Toronto, is building brick and stone steel skeleton retort house, Parliament st., Toronto. Bond & Smith, Temple Building, Toronto, are the architects.

N. P. Tanguay, Weedon, Que., has placed an order with the Jenckes Machine Co., Sherbrooke, Que., for a Crocker Turbine complete with gate, draft-tube and gearing for his sawmill at that place.

The Great North Western Telegraph Co. is installing a new heating system in its large building in Montreal, using the Kingsley water tube boiler installed by E. A. Wallberg, Montreal. David Ogilvy is the architect.

Ed. Mohun, C.E., Victoria, B.C., has made an examination of Rossland, B.C., with a view to scientific sewage disposal, and has reported in favor of a sewage farm below the town, with settling tanks to collect the solids.

G. B. Burland. Montreal, has installed a Kingsley water tube steam boiler plant in the Union Card and Paper Co.'s new works. This is the second order that Mr. Burland has given for Kingsley boilers after using them for four years.

It is reported that a European petroleum syndicate, which controls the immense oil wells at Baku, has purchased the property of the Newfoundland Oil Co., situated on the West Coast of Newfoundland. The price paid is said to have been upwards of $400,000.

The work on the large C.P.R. station and office building in Vancouver, B.C., and the C.P.R. Hotel, at Revelstoke, is progressing rapidly. Most of the materials are procured in the West, and the steel structural work is supplied by E. A. Wallberg, Montreal.

John McDougall Ltd., Caledonia Iron Works, Montreal, had a contract for water filtration with the town of Windsor, N.S., which was set aside by the water commissioners upon a vote of the citizens. They brought suit and recovered the full amount for work done.

If Brantford and Kingston do not grant large bonuses to the Dominion Cotton Mills Co. the factories of the company will probably be concentrated at Three Rivers, Que., where electric power can be had from the Shewanegan Falls. About 5,500 hands are now employed

The Frost Wedge-Lock Wire Fence Co., Cleveland, Ohio, intends starting a branch in Canada, and is corresponding with Welland, Ont., to ascertain what inducements the town is prepared to offer. All the company ask is 1,500 to 2,000 square feet floor space and six-horse power.

The Montreal contracting and building firm of A. Lebeau & Co. has assigned with liabilities aggregating some $60,000 in all, some $55,000 of which is due on mortgage. A demand of assignment was made in March, which they contested, but a second demand results in an abandonment of their estate.

The Laurie Engine Co., has recently installed in its works a high pressure compound Corliss Engine and a Kingsley water-tube boiler plant designed for 175 lbs. working pressure. This is considered in every way a model and a highly economical plant. The Kingsley boilers are installed by E. A. Wallberg, Montreal.

F. B. Gaylord, W. Gerhauser, S. T. Miller, F. A. Goodrich and A. O. Cowles, Detroit, U.S., and E. W. Rathbun and F. S. Rathbun Deseronto, Ont., have been incorporated as the Deseronto Iron Company, Limited, to carry on, in all their branches, the operations of mining, milling, reduction and development, with a capital of $990,000.

The General Engineering Co., of Ontario, Limited, has published a neat volume "Smokeless Heat," which describes the mechanism and application of the Improved Jones Underfeed Mechanical Stoker. A large number of these stokers have already been installed in the large power plants in Toronto and the neighborhood with most satisfactory results, it is stated.

A. C. Hutchinson, architect, Montreal, recently had tests made of the new Kingsley water tube boilers in the Ottawa General Hospital These tests gave highly economical results, exceeding the maker's guarantees by 10 per cent This type of boiler was used in nearly all the recent Ottawa work, including the American Bank Note Co.'s Works, the C. Ross Co.'s building, the Russell Theatre, the Sun Life Insurance Building, the Hotel Cecil, the Harmony Hall, and the Grand Opera House. These boilers were installed by E. A. Wallberg, Montreal.

Belleville, Ont., has been negotiating for the removal of the Thames Iron Works from Norwich, Connecticut, to that place, and has on the report of a deputaiton which visited Norwich, unanimously resolved to submit to the electors a by-law granting a bonus of $50,000, a site of ten acres, free water, exemption from taxation for ten years, and to pay the duty on the plant, which will be removed from Norwich. The company, the chief member of which is F. Mitchell, will first erect a rolling mill, and subsequently, if profitable opening be found, a smelting furnace, nail factory, etc.

The Alberta Railway and Coal Co. has lately caused a survey to be made of the lands lying south of Lethbridge, and proposes to put in irrigation ditches. As the country is adapted in every sense for

irrigation, this will open up for cultivation an immense tract of land, which at present is only used for grazing, owing to its dryness. Where water has been applied in gardens the growth has been very luxuriant. It is expected that on completion of the system there will be a large influx of settlers from the United States, who understand and appreciate irrigation better than Canadians. The Kootenay market for hay, oats, vegetables, etc., will be quite close to this land.

The old suspension bridge across the Niagara River, connecting the Queen Victoria Park with Niagara Falls, N.Y., has been converted into an arch bridge of the same model as the Grand Trunk's new single-arch bridge. The steel arch was built up from either side of the river directly under the platform of the old bridge, and the work of alteration did not obstruct traffic over the bridge, except for a very short time. Both the arch bridges across the Niagara were designed and built under the supervision of L. J. Buck, C.E., New York. The new bridge is of the same pattern as the one built for the Grand Trunk, but is larger and has a greater span of arch, but is not calculated to sustain such heavy traffic as crosses the railroad company's bridge. The steel arch of the new bridge has a span of 840 feet, and the full length of the bridge is 1,240 feet. The length of the arch in the Grand Trunk bridge is 550 feet, and the length of the bridge, including approaches, is 1,100 feet. The centre of the new bridge is 190 feet above the river. The material of the old suspension bridge is to be used in the construction of a new suspension bridge across the Niagara River from Lewiston to Queenston.

The tenderers for the Port Colborne, Ont., waterworks, in whole or in part, are: St. Lawrence Foundry Co., Toronto; Londonderry Iron Co., Nova Scotia; Adam Hope & Co., Hamilton; Gartshore, Thompson & Co., Hamilton; Hamilton Fire Escape Co., Hamilton; Drummond, McCall & Co., Montreal; Kerr Engine Co., Walkerville, Ont.; Rumsey & Co., Seneca Falls, N.Y.; Northey Mfg. Co., Toronto; Goulds Mfg. Co., Seneca Falls, N.Y.; J. W. Ruger Mfg. Co., Buffalo; Walsh Boiler Works, Springfield, Mass.; R. Brown & Sons, New Glasgow, N.S.: C. Richmond, Humberstone; Hunter Bros., Kincardine, Ont.; Geo. W. Moore. Buffalo; J. G McKay, Thamesville, Ont.; W. B. Wilson, Buffalo; J. E. Kennedy, Owen Sound, Ont; Clark & Connelly, Toronto; McQuillan, & Co., Toronto; W. W Reid, Niagara Falls; Craig & Lynch; Hill & Gowanlock, Toronto; Fairbank, Morse & Co. The following are the lowest tenders: For cast iron pipes, hydrants, valves, etc., St. Lawrence Foundry Co., Toronto, $7,255 50; for complete system, Clark & Connelly, Toronto, $17,800; McQuillan & Co., Toronto, $18,960; Hill & Gowanlock, $16,899. Lowest figures, taking separate bids for completed work, $16,503 78. Pumping station was W. B. Wilson, Buffalo, $900. For stand-pipe, Walsh Boiler Works, Springfield, Mass., $995.

Mining Matters.

During one fortnight recently over forty miners left Johannesburg for the Klondyke.

The discovery of rich gold-bearing deposits is reported from Lake Clare, twenty-one miles north of Ste. Anne de Chicoutimi, Que.

The Jenckes Machine Co., Sherbrooke, Que., shipped on the 5th inst. a complete 10-stamp mill to the Cariboo Mining, Milling and Smelting Co., Fairview, B.C.

The Jenckes Machine Co., Sherbrooke, has equipped the Athabasca Mine, Nelson, B.C., with complete hoisting outfit and boiler. This mine is sure to become a producer of prominence.

D. S. McArthur & Co., Nelson, B.C., are developing their properties, and recently purchased, through the Rossland branch, from the Jenckes Machine Co. a complete hoisting plant.

The Monte Cristo Mine continues sinking in the main pit, and has lately added a No. 6 Cameron vertical pump, purchased through the Rossland branch, from the Jenckes Machine Co., Sherbrooke, Que.

The Rat Portage Diamond Drill Company has shipped machinery to Shoal Lake, where work has been commenced on the Cornucopia property.

Rossland, B.C., has organized a mining school by means of local subscriptions. About sixty students began the study of geology there early in April.

Mining in Newfoundland is likely to become more active very soon. The agents of at least five wealthy companies are at present in the Island examining properties, chiefly copper, with a view to purchase.

The Dundee Mining Company, Rossland, B.C., has just let a contract for furnishing material for a three-line gravity tramway. The price is $1,400. The company will erect trestles and install the tramway.

The Bonanza Nickel Mining Company at Wahnapitae, Ont., has erected a ten-stamp mill at the Mammoth gold mine, which is now in operation under the management of Henry Dierlamm, formerly of Chesley, Ont.

W. M. Slack, Petrolea, Ont., Fred. Beresford, London, and John MacRae, Petrolea, are on their way to Edmonton, N.W T., to test an oil well for the Dominion Government. They expect to drill 2,200 feet before they strike oil.

George Wilson, contractor, Kingston, Ont, has bought a large mica mine situated two miles back of Gananoque, Ont. The mine was opened some time ago, and $2,500 spent on it. Samples of the mineral show it to be of a superior quality.

The London and British Columbia Gold Fields Co., Ltd., Rossland, B.C., is developing its property, and recently added to its equipment a 6 x 8 special hoisting engine and 40-h.p. locomotive-type boiler from the Jenckes Machine Co., Sherbrooke, Que.

Prof. Frank D. Adams, professor of geology and paleontiology in McGill University, has declined, out of regard to the wish of the university, the position of Provincial Mineralogist of British Columbia, the position until recently held by Prof. Carlyle.

The Coleraine Mining Company is reorganized, and the new directorate has employed A. Davis, their consulting engineer, to put in a complete new plant for mining at Black Lake, Megantic, Que. The company has orders for the entire output for three years.

The Jenckes Machine Co., Sherbrooke, Que., recently supplied the Sydney mine at North Sydney, Cape Breton, with a special coal hoisting engine, to be operated by compressed air. The compressor was supplied by the Canadian Rand Drill Co., Sherbooke, Que.

Geo. M. Webster & Co., Quebec, coal handlers, are improving their facilities for unloading steamers, and for this purpose have placed an order with the Jenckes Machine Co., Sherbrooke, Que., for four of their double cylinder rapid coal-hoisting engines with boilers.

The Dominion Coal Co. is improving the facilities for unloading from its steamers at Levis, and has purchased for this purpose four 8¼ x 10 double cylinder special coal hoisting engines from the Jenckes Machine Co., Sherbrooke, Que., with a powerful 100-h.p. locomotive boiler.

The British American Corporation, Rossland, B.C., is pushing the development of its properties, and the Jenckes Machine Co., Sherbrooke, through its Rossland branch, has supplied it with special pumping apparatus for the Nickel Plate, and Columbia and Kootenay mines.

Manganese iron ore is freely imported into the United States from various countries in Europe and South America. Extensive deposits of this ore exist in New Brunswick and Nova Scotia, and it would appear that Canada is losing a profitable trade which is lying right at her doors.

The Smuggler Gold Mining Co., headquarters Toronto, has decided to put a 20-stamp mill on its property at Fairview, B.C., this summer, and an order has been placed with the Jenckes Machine Co., Sherbrooke, Que., for Corliss engine, boiler, 20 stamps, vanners and four miles of aerial tramway.

The Bell Asbestos Co., Thetford Mines, Que., is changing over the system of operating the mine hoist, and for this purpose has placed an order with the Jenckes Machine Co., Sherbrooke, Que., for a 100-h.p. steel tubular boiler, and have also purchased from the same company a small locomotive for shifting cars in pits.

The Canadian Copper Co., of Copper Cliff, Ont., is fitting a new shaft, has placed an order with the Jenckes Machine Co., Sherbrooke, for two 100-h.p. special steel boilers, one 12 x 15 double cylinder double drum winding engine, three large steam pumps and rock breaker, and necessary gear for operating them.

The annual meeting of the Newfoundland Oil Company was held recently, the majority of the shareholders being present, and President Thompson occupying the chair. The report of the Secretary-Treasurer which was presented and adopted was of a most satisfactory nature. The officers of last year were re-elected.

Supplementary letters patent have been issued by the Quebec Government granting the Combustible Gas Company an exclusive privilege of working and making use of the combustible gas which exhales in various parts of the province, for the purpose of lighting, heating, and supplying motive power until August 30th, 1901, inclusive.

E. T. Wilkie, C.E., Carleton Place, Ont., and Andrew Bell, C.E., Almonte, Ont, are in charge of the survey now being made for a tramway to connect the iron mines now operated by the Hamilton smelting works, in Darling township, Lanark county, Ontario, with the Kingston and Pembroke Railway at Flower Station. The line may be ultimately an electric railway.

A Rossland, B.C., report states that the recent strike on the Jumbo is a good one. The body of ore was struck in the lower tunnel, and the whole force of the working is said to be in rock assaying $113 to the ton. The tunnel referred to was started in August, 1896, and has now been run in 800 feet in the ledge. It is 200 feet below the ore body discovered two years ago, and gives a "back" of 350 feet.

Vancouver, May 5.—The city council has, subject to the ratifying vote of the taxpayers of Vancouver, agreed to pass a by-law granting to the Van Anda Gold and Copper Mining Company a subsidy of 40 cents a ton on ores smelted by it at a smelter to be built and operated at some point within five miles of the limits of Vancouver, the total subsidy payable to be limited to an aggregate of 125,000 tons, making $50,000 in all.

The Vancouver, B.C., city council has accepted the offer made by the Anglo Continental Public Works Company of London, Eng., and that city is to have a smelter. The proposition in brief was as follows: It is stipulated that the city shall give the company a bonus of 50 cents per ton on ore treated, not exceeding 30,000 tons in any one year, in return for which the company shall give the city £50,000 in preference 10 per cent. shares.

At Belle Island, in Conception Bay, Newfoundland, the Nova Scotia Steel Co. have developed extensive iron deposits. The company is the lessee of four grants of land, each of one square mile, and during the past few years have erected an extensive and costly plant for the mining and handling of the ore. The bulk of the ore has been shipped to New Glasgow, where it is mixed with Nova Scotia iron and produced pig iron. The company employs an average of 200 men, and the deposits are estimated to contain some 40,000,000 tons of ore and the assays give from 48 to 56 per cent. of metallic iron.

The directors of the War Eagle Consolidated Gold Mining Company have decided to begin paying monthly dividends of 1½ per cent. The first dividend is payable on 1st June. The company is capitalized at $2,000,000, in one-dollar shares, of which 350,000 still remain in the treasury. The June dividend upon the 1,650,000 shares in the hands of stockholders will total $24,750. The mine ships to the C.P.R. smelter at Trail 100 tons per day, or 3,000 tons per month. The smelter people buy the ore as it arrives, upon its assay value, the War Eagle netting about $17.50.

The Canadian Pacific evidently intends to supplement its network of railways in the Kootenay by a system of smelters. Having bought the Heinze smelter at Trail, B.C., the C.P.R. is now adding to its plant two new blasts, which will bring the daily capacity up to 500 tons It is also stated that the railway company will erect a lead smelter at Trail, the plant to be in operation before the first of next year. This lead stack will adjoin the property acquired from Heinze, and will have a capacity of 150 tons a day, the idea being to treat the Slocan and Ainsworth galena ores in conjunction with the pyrrhotite ores of Rossland camp.

At the annual meeting of the Toronto Smelting Company, Limited, which was held in Canada Life Building, Toronto, recently. James Kendry, M.P., was elected president; J. D. Hay, Toronto, vice-president; W. A. Hungerford, Belleville, general manager; F. C. Flannery, secretary-treasurer, The company proposes to establish smelting works at Madoc, if satisfactory arrangements can be made; if not, they will establish works at Duoro or Marmora. The company has already made tests at Millbridge, and the results have been so satisfactory that it has decided to erect a custom and testing smelter. The company intend to pay special attention to arsenic, as the mispickel ores of this region are especially noted for the production of arsenic.

The Ontario Bureau of Mines has received news confirming the reported discovery of placer gold near Sudbury. The finds are said to be on the Vermillion River, to the north of Sudbury, probably at the head waters of the river, near the Height of Land, west of Lake Wahnapitae. The Department has received numerous applications for mining location in this district recently, but none has been granted, as this part of the country has been withdrawn from sale on account of its valuable timber, which has not yet been disposed of by the Government. Some prospectors who have come out state that the gravel is abundant, but the pay is not high, and that only on a large scale would the diggings pay to work. Others say that three to five dollars a day can be easily taken out.

The Crow's Nest Pass Coal Company, Fernie, B.C., expects to be able to supply the smelters in Montana, Idaho, Northport, Trail and Nelson, which are at present using the Welsh coke, which costs them from $16 fo $18 per ton. The Crow's Nest Co. hopes that it will be able to furnish better coke to the two Canadian plants for $7 per ton. It will, of course, be higher delivered in the United Sates. The Crow's Nest coke is said to contain 95 per cent. fixed carbon and only 4 per cent ash. . It is estimated that by this reduction in the price of fuel the smelters will be able to save $1.50 per ton in the cost of treating ore. The present consumption of coke at the smelters which the company hopes to supply is as follows: Northport, 40 tons per day; Trail, 60 tons; Hall Mines, 40 tons; Everet, 60 tons; Tacoma, 40 tons; Great Falls, 150 tons; Helena, 50 tons; Butte and Anaconda, 400 tons. It will at the outset be called upon to furnish 840 tons a day.

A letter from Rossland under date May 11th gives some items of interest respecting what is doing in the Kootenay mining district. Development is active, and the hopes of both prospectors and miners appear to be high. The War Eagle mine proprietors have been negotiating with the General Electric Company about a compressor plant and elevator, and have at last closed a contract for the same. The Boundary Creek country is progressing up well, and a ten-drill compressor plant, with hoisting-engine, heaters and pumps, is under contract from the Cooper Company, of Montreal, to be furnished to the British Columbia Copper Company, of Anaconda. At the Le Ro smelter they are said to be running 250 to 300 tons of ore per day, principally from the Le Roi mine. At the Hall mines smelter, at Nelson, by their published report, the output for twenty days up to 30th April was 218 tons of matte from 4,734 tons of ore, where in 31 days ended 2nd April, they had turned out 357 tons matte from 7,437 tons of ore treated. The new superintendent of the smelter, R. R. Hedley, is proving his ability and has, it appears, done more successful work than either of his predecessors, even although he is a Canadian, born and educated outside of "Europe." The people here, or perhaps I should say some of the people here, did not like what Mr. Hedley said, in 1896, about the character of the Rossland ores, but he is proving to be about right in his estimates of what can and cannot be done with it. Other experts were planning and working on a basis of 60 and 65 per cent. copper matte. But the matte does not pan out anything of the sort. In fact the Hall Mines people are at present producing only a 45 per cent. copper matte, which is a very different story. It will give you an idea of the extent of the activities in this part of Kootenay, the writer says, if I tell you that, as I learned from the custom authorities, there was raised and shipped through the Nelson custom house 31,920 tons of ore, valued at $3,116,212 during the period from 1st January to 30th April, 1898. The banks are finding that it is worth while to look after business here, and I am told that the Bank of Montreal will very shortly erect a handsome three-story building in Rossland for banking premises and other purposes.

Marine News.

The Yarmouth Steamship Co.'s new steamer "Express" has been fitted up at Liverpool. She will carry 200 passengers and will arrive at Yarmouth early in June.

The Bertram Engine Works Co. have secured the contract to build a steel grain-carrying propeller to be used in place of the Rosedale. The new vessel is to be 255 feet long by 43 feet beam.

The Lake Champlain and St. Lawrence Ship Canal Company charter has been granted by the Dominion Government, but it is not to become operative without the consent of the Governor-General-in-Council.

L. Lacouture, Sorel; J. O. Blondin, La Baie des Peres; D. Gillies, M.P.P., Carleton Place, Ont.; J. Gillies and J. Gillies, Breaside, Ont., have been incorporated as the Lac Temiscamingue Navigation Company, Ltd., capital $25,000.

The port of St. John, N.B., did a much larger business during last winter than the one previous. Last winter there were 53 steamers sailed as against 46 the winter before, and there were 3,639,000 bushels of grain trans-shipped as against 1,436,000 bushels in 1896-97.

Capt. Macauley, of the Dominion liner "Canada," has been appointed to the command of the company's new steamer "New England." His successor will be Capt. Maddox, of the "Scotsman." The latter will be commanded by the second officer, Capt. Skrimpshire.

The large freighter built at Leigh's shipyard, Victoria, B.C., for Capt. W. Grant, was launched a short time ago The steamer is 107 feet in length with 24 feet beam and 7 feet deep. She will have a speed of eight knots and will enter the freighting business. Spratt & Gray are fitting her with machinery, and Shaw's Iron Works will supply her boiler.

Murray & Munroe, Pembroke, Ont., have completed the new wharf at L'Orignal, Ont.

The Richelieu & Ontario Navigation Company has declared a semi-annual dividend of 3 per cent.

The C.P.R. is arranging for the construction of a $6,000 dock at Kaslo, B.C, similar to the one at Nelson.

The steamers "New York" and "Empire State" will supply a daily service down the St. Lawrence rapids this summer, running from Clayton to Montreal. The Folgers of Kingston are the proprietors of the line.

A. J. Harvey & Co., St. John's, Newfoundland, have bought the steamer "Lucerne" from the Allans, to carry pulp and general freight from Newfoundland to England. Capt. D. Taylor has been appointed to the command.

James Playfair & Company's tug, the "Magnolia," was launched at Midland, May 24th. She is 140 feet long, 21 feet 6 inches beam, and will draw, coaled, fourteen feet of water. She will be used principally for towing and wrecking.

The earth under the River St. siding and the coal docks, Owen Sound, slid into the river recently, allowing both to sink about five feet for a distance of over two hundred feet. Dredging the harbor is supposed to be responsible for the slide.

The Furness line will formally take over the business of the Canada and Newfoundland Steamship Co., which it has bought, on July 1st. The four men who owned these boats were: David McPherson, W. Barry, P. Pierson, and S. M. Brookfield.

Two new passenger steamers of the Dominion Line will be on the St. Lawrence route from Montreal this season, viz., the "Dominion," a fine twin screw steel ship of 6,000 tons, equal to the "Canada" in finish, and the "Yorkshire," also new and of similar construction and equipment.

Captain Thomas Howard, the late harbor master of Montreal, who died recently, was well known and much respected in commercial circles in Montreal, where he had been a resident fifty-six years. He was born at Shinrone, Queen's County, Ireland, on Sept. 15th, 1826, and came to Canada in 1842. For a time after his arrival he was in the employ of the late Hon. John Hamilton, and later entered the service of the Richelieu & Ontario Navigation Company. For some years he commanded the "Banshee," "St. Lawrence," "Magnet" and other vessels of the company plying between Montreal, western ports and the Saguenay, and was subsequently appointed manager of the Ontario division of the company. In March, 1881, he was appointed harbor master. He had thus been connected with the business of the port for nearly half a century.

A large deputation from Kingston, Prescott and Deseronto, waited upon the Minister of Marine and Fisheries recently, to request that the department should make an order suspending the regulations for this year, which require American passenger steamers to comply with the same regulations as Canadian passenger steamers. The Canadian inspection requirements are not the same as American, differing particularly with respect to life preservers and the inspection of boilers. It has been the custom in the past to accept the American inspection, but an amendment to the Canadian Act requires conformity to the Canadian regulations. The deputation comprised delegates from Kingston and other towns and was accompanied by the following members of parliament: Messrs. Britton, Charlton, McGregor, Frost, Hurley, Edwards and Snetsinger. The Minister promised to give the request a favorable consideration if possible.

The Manchester Liners, Limited, is formed to acquire and run three steamers between Manchester and Montreal in summer, and St. John, N.B., in winter. These steamers are to cost £90,000 each, are to steam twelve knots an hour, and to have a carrying capacity of 8,500 tons. One is to be ready in August and two in the spring of next year. But two steamers are to be immediately acquired for the work, so that the approaching autumn and winter will now be amply provided for. There is no question of the extent of the traffic available, and we share the confidence of the directors that the new service will have remunerative results. The authorized capital is £1,000,000 in shares of £10. Sir Christopher Furness is chairman of the company, and his experience is security that the company's business will be conducted with intelligence as well as vigor.

The Pembroke Navigation Company has launched the new vessel recently built for them in Toronto by the Polson Company. She is built of iron and is 125 feet in length, with a twenty five foot beam, and is capable of attaining eighteen miles an hour. The cost was $30,000.

The Donnelly Wrecking Company of Kingston have purchased the sidewheel steamer "Columbia," which ran ashore at Sarnia last summer. She will be put on the government dry dock at Kingston. The "Columbia" was formerly worth $10,000.

Mr. O. E. Young, of Magog, is building a small pleasure boat for Mr. L. B. Ward, of Brooklyn, N.Y., to be used on Lake Memphremagog, and an order has been placed with the Jenckes Machine Co., of Sherbrooke, Que., for one of their 7 h.p. Dake marine engines, with boiler to run the same.

The two steamers for the Dominion Atlantic Railway Company, being built on the Humber, England, are the "Prince George," which will reach this country about the middle of June, and the "Prince Arthur," which will come a fortnight later. Both steamers are alike. They are 300 feet long, 38 feet beam, 15 feet draught and 6,500 h.p. They have a speed of 21½ knots on the measured mile and are guaranteed 19½ knots at sea in any weather. Each engine has four sets of cranks instead of the usual three. All the heating will be done by electricity and they will have electric fans.

An announcement of some commercial interest to Canada is to the effect that the enlargement work on the Erie canal will have to be suspended for at least two years. Through some miscalculation or mismanagement the nine millions voted for the work has been expended, and the waterway is available for no larger craft than have navigated it for years past. It will take two years, under the law, it seems, to obtain authorization for a further loan, and some time more to complete the enlargement operations. Meantime, if the present programme is carried out, next season will see the enlarged St. Lawrence canals available, and Canada will have at least a year's start of New York in the use of the improved waterways.

The Polson Iron Works, Toronto, have just shipped a steamer, which will be the first to reach the Yukon, intact from this port. The boat started from here to Vancouver on two C.P.R. flat cars, whence it will be forwarded on an ocean steamer to the Yukon—an exploration boat, built for either day or night service, and to accommodate four mining engineers and crew. She is called the "Burpee," after her purchaser, and is, length on water-line 45 feet, over all 53 feet, beam 9 feet, draught of water 10 inches. She was designed by W. E. Redway, is built with a steel frame and wood planking, with boiler and engine aboard ready for immediate service on reaching her destination. Her speed will be about 10 to 12 miles; cost, $6,000.

Railway Matters.

The C.P.R. will build a new station at Almonte, Ont., this year, it is expected.

The management of the G.T.R has decided to construct 250 refrigerator cars for the general service of the system.

There are at present 200 men at work in the Perth, Ont., car shops of the C.P.R., and work is continued each night up till midnight.

Dutton, Ont., has defeated the by-law granting a bonus to the L.E. & D.R.R. in aid of the extension from Ridgetown to St. Thomas.

The bill of the Ottawa, Montreal and James Bay Railway Co., was passed by the Dominion Government recently. The intention is to build north from Labelle, about 100 miles north of Montreal, and to continue to the shores of Rupert's Bay, a distance of 375 miles.

It is stated that Louis Coste, chief engineer of the Dominion Public Works Department, has pronounced against the Mackenzie-Mann Teslin Lake Railway scheme, and that it was on account of this hostile report of the government's own engineer that Sir Wilfrid Laurier telegraphed to British Columbia that the ministry could not support the scheme.

The Ottawa and New York Railway Co. has offered to build its workshops in Ottawa if it is given a bonus of $100,000.

The case of Hannaford v. Grand Trunk is postponed for some time, because it has been decided to appoint a commission rogatoire to take the evidence of Sir Charles Rivers-Wilson and Messrs. L. J. Sargeant and Linley, the commission being returnable on June 18th. Charles Russell, son of the Lord Chief Justice, will act as the commissioner.

The city of Montreal has offered a free site for an office building for the G.T.R., and the Grand Trunk has accepted the gift. This finally disposes of Toronto's fancied prospect of securing the office. The terms upon which the site will be given, are as follows: That the company be offered part of the McGill street property, owned by the city, as follows: 199.4 feet on McGill street, and 135 feet on St. Paul and William streets, respectively; the building to cost not less than $250,000, the assessment to be levied on that amount only for a period of twenty years, this latter arrangement to be submitted to the legislature for ratification. The plans of the proposed building to be submitted to the city for approval.

Sixteen "Mogul" engines have been purchased by the C.A. & O.A. & P.S. Railways for the freight business. The engines are much larger than the ordinary passenger locomotives. Compared with the new engines the old ones look quite small. Ten of these new engines are of the ten-wheel "Mogul" type and each weighs 156,000 pounds without the tenders. They have three couple-wheel drivers and are equipped with compound cylinders. The other six engines are of what is known as the consolidated type of "Mogul." They are equipped with four couple-wheel drivers, and have compound cylinders. They weigh 173,000 pounds exclusive of tenders. The engines will be used exclusively for freight.

It would seem that the C.P.R. has definitely decided to push forward a line from Toronto to Sudbury at once. Two corps of surveyors are already at work in charge of H. D. Lumsden, who surveyed the Crow's Nest Pass road. One party will spend the entire summer in the Nipissing district, and another party will start out from Coldwater and survey southward through Barrie to the Orangeville branch of the G.T.R. at Kleinburg or Bolton. The new line will take the shortest cut between Parry Sound and Sudbury, and will extend inland so as to open up the Nipissing and Parry Sound districts. From Parry Sound the road will extend southwards to the west of Muskoka lakes, and across the Muskoka river at Bala, thence to Muskoka wharf and south-west across the Severn river to tap the Midland branch of the G.T.R. at Coldwater. The new line will save 55 miles haulage between Toronto and Winnipeg, and will be completed in about two years.

The British Columbia Government has passed a railway aid bill, which provides $4,000 per mile for the following railways: From Penticton to Boundary Creek, 100 miles; from Robson to Boundary Creek, 80 miles; from the Pacific coast to Penticton, 230 miles; from Bute Inlet to Quesnell, 230 miles; from Teslin Lake to a British Columbia seaport, not exceeding 400 miles. The act provides for the commencement of the Penticton-Boundary and Robson-Boundary lines on or before the 8th of August, 1898, and on the coast to Penticton and Bute Inlet to Quesnelle on or before the 8th day of May, 1898, work to commence on the Yukon line on or before the 8th day of June, 1898. The bill further stipulates in the case of the line from Robson to Boundary being built by a company entitled to a land grant, that such company shall relinquish its claim to the land grant for such portion of its line on accepting cash subsidy. It was expected that McKenzie & Mann would build this line but they have notified the British Columbia Government that they cannot carry out the work.

Bystander, in the St. John's, Que., News, commenting on the Hannaford v. G.T.R. case, and contrasting the old regime of that railway with the new, says: "Mr. Hays is down at his work at nine o'clock in the morning. He generally walks to the Point, but, if in a great hurry, he will permit himself the luxury of a street car. This may seem a trifle in a man who can think as clearly at ten as at nine o'clock, but it has worked a revolution in the Grand Trunk system. Punctuality is understood for the first time in the history of the company. Duty means enthusiastic and earnest and unflagging work. Nepotism has been taken by the shoulders and bundled out of the thought of the new management. The sole test is merit. The humblest person has as much chance of preferment as the nephew of the president. Mr. Hays is a direct, simple, democratic personality, and every officer under him is accessible to the public at all times. The new manager would be vastly surprised to see one of his officials coming down to his office in his carriage at eleven o'clock in the day, as was the case under the old regime.

Electric Flashes.

Belleville, Ont., Street Railway is to be extended to a park on the lake shore.

Free power is obtained from the Canada Coal and Railway Company to run the electric light plant at Joggins, N.S.

Bonuses are being sought for the proposed electric road from London, through Stratford, Arkona and Thedford, connecting the Canadian Pacific with the Grand Trunk.

S. H. Kent, secretary of the Hamilton, Ont., Committee on Municipal Lighting, is carrying on an extensive correspondence in pursuit of information regarding civic electric lighting in other municipalities.

Simeon H. White, Andrew L. Price, C. Geo. Armstrong, Walter J. Mills and Hamilton B. Price, Sussex, N.B., have applied for a New Brunswick charter as The Little Salmon River Telephone Company, Limited, capital $1,500.

The by-law authorizing the agreement with the Montreal Street Railway Company was voted on at Verdun recently, when eighty-three proprietors voted in an approval of an immediate street railway service, and only six voted contrary. The by-law was therefore affirmed.

At the annual meeting of the Quebec Electric Street Railway Company, Andrew Thomson was elected president; E. W. Methot, vice-president; and W. Shaw, Jno. Breakey, Judge Chauveau, E. E. Webb and Harold Kennedy, directors for the current year.

A company from Bellechasse has asked for Quebec letters patent under the name of the Ste. Philomene Telephone Company. It will place telephones in the counties of Bellechasse, Montmagny and Dorchester, with headquarters at St. Raphael, and a capital of $1,500.

The Toronto City Council is engaged in a dispute with the Electric Light Company, the result of an effort on the city's part to compel the company to light the Island, which is within the city limit, at the city rate of 20¼ cents per lamp per night.

The contract for covering the pipes and boilers in the power house of the St. John Railway Co., St. John, N.B., has been completed by the Eureka Mineral Wool and Asbestos Co., Toronto. This company has had several large covering contracts of late, not a few of which were repeat orders.

The Niagara Falls, Ont., Electric Light Company has purchased machinery from the Westinghouse Company, to provide electricity for heating and power purposes, in addition to the present lighting system. The changes that will be made at their power house, and wiring of streets, etc., will involve an expenditure of about $10,000. They will be able to supply from one to seventy-five horse-power 24 hour service.

The plant of the Acetylene Light, Heat and Power Company, known as the Carbide works, at Niagara Falls, N.Y., was sold under chattel mortgage proceedings a short time ago. The action was brought by the Electro Gas Company, of New York, who held the mortgages, and the plant, machinery and power rights were bought by them for about $85,000. The Electro Gas Company will continue the business.

The Kingston Street Railway has about completed a branch line to the outer G.T.R. station on Montreal Street, going by way of Bagot and Montreal streets. It will be in operation early this month. The line will be in competition with the Grand Trunk Railway, which has reduced fares to five cents per trip. It is expected that much of Princess Street will be double-tracked and a belt line made on the northerly side of the city by way of Division, Pine and Montreal streets.

A dynamo and a number of lamps have been supplied by the Royal Electric Company to the Soulanges Canal.

Wood Bros., Brantford, Ont., have recently bought from the Royal Electric Company a 70 h.p. synchronous motor.

The Montmorency Power Company, Quebec, has bought a 600 K.W. "S.K.C." generator from the Royal Electric Company.

C. E. Campbell, Weymouth, N.S., has been supplied with a direct-connected lighting plant by the Royal Electric Company.

A 300 K.W. "S.K.C." synchronous motor has been bought from the Royal Electric Company by the Golden Cache Mining Co., B.C.

The contract for building the Canadian branch of the Carborundum Works, Niagara Falls, Ont., has been secured by James Harrison. The structure will be frame 30 x 60 feet.

The B. C. Bullion Extracting Co. has made a contract with the Canadian General Electric Co. to supply a 100 horse-power synchronising motor, and a 50 horse-power induction motor for their works, which are about a mile and a half from Rossland, B.C.

John Forman, importer of electrical supplies, 644 Craig street, Montreal, has recently issued catalogue "B," which contains a great deal of useful information for all users of electrical apparatus of any kind. Edison lamp, Ericsson telephones, Anchor switches, and a great many other standard appliances, as well as numerous novelties, are always carried in stock.

J. R. Scott, an enterprising citizen of Napanee, has closed a contract with the Canadian General Electric Co. for a 100 K.W., 4,000-volt three-phase generator of the revolving field type, for the purpose of supplying light and power to Napanee from a water-power eight miles distant. He will also supply light and power to intermediate points such as Napanee Mills, Camden East, and Newburgh.

A meeting was held at the Halifax Hotel, Halifax, N.S., April 12th, 1898, at 3 p.m., for the purpose of organizing an association of all those interested in the electrical industries in the Maritime Provinces. The following gentlemen were present: John Starr, C. E. Harris, Jas. Waddell, N. L. Ross, J. H. Winfield, L. A. Somers, J. D. Briggs, P. Mosher, A. Miller, John Griffin, J. A. Anderson, P. R. Colpitt, F. A. Bowman, E. T. Freeman, I. H. Smith.

The West Kootenay Power and Light Co. is rapidly completing its power plant at Bennington Falls. The poles are set and two wires are stretched between the falls and Rossland, a distance of 31 miles. The line goes into Rossland over the Monte Cristo Mountain, and it is the intention of the company to stretch another wire so that in case of accident there will be no interruption of the current. The first cost of the plant is placed at $125.000, but it is said that the expenditure upon it may be extended to half a million.

A Dominion charter has been granted to the North Shore Electric Railway Company, the applicants being: Wm. Owens, Westmount; V. W. Larue, Quebec; Wm. Strachan, R. Prefontaine, Thos. Gauthier, and Albert J. Corriveau, Montreal. Mr. Corriveau says that it is intended to use power generator at the Shawenegan Falls. The railway is to start at Three Rivers, and general powers are given for the counties on the north shore of the St. Lawrence. Privileges are conferred similar to those granted to Montreal and Southern Counties Railway Company.

E. A. C. Pew's project to produce water power by the construction of a channel from the river Welland, east of Wellandport, to the river Jordan, although remaining in abeyance for some time past is coming to the front again. The works will be gone on with if satisfactory contracts can be made for disposing of the power when generated. Wm. Pearson, C.E., Oswego, has, it is said, pronounced the scheme a feasible, safe and practical one, pointing out that the great source of expenditure in connection with the development of power at Niagara Falls—the construction of wheel pits and tail race—will not be necessary in this project. The principal expense will be the excavation.

Barrie, Ont., is advertising for tenders on an electrical installation to consist of a street lighting plant of 65 arc lamps of 2,000 candle power, an alternating current plant to supply 2,500 incandescent lamps for private lighting, and a direct current 500-volt power plant to furnish cheap electrical motive power to manufacturing establishments. An up-to-date electrical fire alarm system will also be installed. The estimated cost of the entire equipment is placed at $35,000, and as quality of machinery and apparatus will be made a first consideration before prices, the town will, no doubt, obtain a very complete and high-class installation. Tenders will be opened on June 6th next, but the awards will not be made before the ratepayers have voted the necessary moneys. Roderick J. Parke, of Montreal, is the consulting engineer for Barrie.

The C.P.R. copper telegraph line, from Montreal to Vancouver, is now building. The line passes via Vaudreuil and the Short Line to Ottawa, and thence by the main line to the coast. It will be strung under the general superintendency of W. J. Camp, the C.P.R. electrician, in three divisions. The first one will reach from Montreal to Fort William, and will be conducted by Jos. Townsley, with about 100 men, working simultaneously in four gangs. The next division will reach from Fort William to Donald, B.C., and will be under B. S. Jenkins, Supt. of Telegraph, Winnipeg, with three gangs of men. The final division will reach from Donald to the coast, and will be under the charge of J. Wilson, Supt. Telegraph. A great deal of trouble has been experienced by telegraphic companies, through wires coming in contact with each other, through the breaking of the glass insulators by which the wires are attached to the poles. A test was therefore made at McGill University with a view to ascertaining the comparative resistancy of glass and porcelain insulators, with the result that it was found that porcelain resisted much heavier, and a greater number of blows, than the glass. Tests were also made with a thirty-two calibre revolver from a distance of eight feet. The glass flew to pieces at nearly every shot, while the porcelain frequently showed no mark, save the lead from the bullet, and when they did break it was in such a way that, had they been attached to the pole, the wires would not have been affected. The testing of the wire is also going on at the Applied Science Department of McGill, under the care of Mr. Drinkwater. Each day he selects at random a sample of wire from each lot of ten bundles being turned out by the Dominion Wire Mfg. Co., and subjects them to tests in order to insure that they come up to the requirements of the contract. The wire must be .137 of an inch in diameter; one one-thousandth of an inch only of a variation being allowed above or below this gauge. It must be perfectly cylindrical and weigh 300 pounds to the mile; four pounds of a variation being allowed in this distance. Frequent electrical tests are made upon pieces one one-hundredth of a mile in length, to determine the purity of copper used, which must be 97 per cent. Each bundle weighs 170 pounds, and the wire must be in one continuous length, without joint or break. Each six inches of wire must be capable of being twisted thirty times at a uniform speed of one twist a second. The tests show that it will stand forty to fifty twists before breaking. It must stand six close turns around another wire of equal diameter and be unwound without breaking. It must also stand an average breaking strain of 975 pounds, and before breaking it must have stretched at least one per cent. When completed there will be a length of about 2,900 miles of wire.

Personal.

H. M. Bolger, secretary of the Richelieu and Ontario Navigation Co., Montreal, was married a short time ago to Miss Mills, of Quebec.

P. Kennedy, employed in the C.P.R. car shops, Perth, Ont., had his head crushed between two cars, and was instantly killed, May 13th.

R. G. McConnell, of the Dominion Geological Survey, and J. B. Tyrell have left for the Yukon, and will spend the entire season in that district.

H. C. Landon, C.E., Cornwall, Ont., has removed to Austen, Pa., where he will have charge of a section of the Buffalo and Susquehana Railroad.

Frederic Nicholls, managing director of the Canadian General Electric Co., sailed on the "Campana" recently for a visit to England and the continent

Alexander Milloy, after fifty years of service in the Richelieu and Ontario Navigation Company, acting as traffic manager, has retired. G. A. Browne will be his successor.

Wallace Bell, the well-known well sinker, Montreal, has gone to Newfoundland, where he has been asked to help in developing the newly discovered oil regions in the island.

D. J. McDonald, British Columbia inspector of mines, has resigned his position to enter the service of the British America Corporation, under W. A. Carlyle, late provincial mineralogist.

Wm. Bunney, who has been for the past six years in the employ of the Wm. Cane & Sons Mfg. Co., Newmarket, Ont., as foreman, has taken a situation with W. C. Edwards & Co., Ottawa.

Samuel Lyons, head engineer of the Stewiacke, N.S., foundry, was instantly killed a short time ago. He was working at the emery wheel, when it suddenly broke, a portion of it striking him violently over the heart.

O. H. Sheppard has accepted the position of cashier of the Toronto Ferry Company, made vacant by the resignation of Walter Garwood, who has been appointed to a more lucrative position with the Queen City Oil Company, Toronto.

Mr. D.A. Starr, president and manager of the Cornwall Electric Street Railway Co., was waited upon by a deputation of the employees and presented with a handsome gold headed cane, with many good wishes, on the occasion of his birthday a short time ago.

News reached Montreal last month from Liverpool, of the drowning of a well known Canadian Pacific official, T. F. B. Evans, who was agent at Liverpool for the company for the past ten years. Mr. Evans while boating off Bangor, Wales, where he was enjoying a short holiday, fell out of his boat and was drowned.

W. J. Carroll, St. Catharines, Ont., who has been engaged in engineering work upon the Crow's Nest Pass Railway since last September, has received an appointment as chief engineer of the Sindicate Industriel de Sud America, a company formed to build a railroad from Quito to Pailon, on the west coast of South America. The district about Pailon is famous for its rich gold deposits. The company receives from the Government a concession of about seventeen million acres of land.

W. Robert, cashier of the Richelieu and Ontario Navigation Company, received a handsome present and illuminated address a short time ago. The presentation was made by C. F. Gildersleeve, the general manager, representing the staff of officials, and the occasion was the severance of the connections between Mr. Robert and the company. Mr. Robert will shortly leave for Quebec, to fill the position of paying teller in the new branch of the Hochelaga Bank, about to be opened in that city.

Robert N. Stevens, mechanical superintendent of the I.C.R. at Truro, N.S., died at his home there May 18th. He was about 64 years of age, and was well and favorably known both in New Brunswick and Nova Scotia. He has been identified with the I.C.R. ever since it was opened and was engineer of the first train over the road, going as far as Coldbrook. He rose in the service, and was for years mechanical superintendent at Moncton. During the past three or four years he has been mechanical superintendent at Truro.

Milton L. Hersey, the well-known chemical expert and assayer, on whom the degree of Master of Applied Science has been conferred by McGill University, is the youngest son of Randolf Hersey, Montreal. His primary education was by private tuition, and he soon entered the Royal Arthur School, from which he was promoted in 1881 to the Montreal High School. From the latter he graduated in 1885, entering the Department of Applied Science of McGill University the same year. Mr. Hersey graduated from McGill nine years ago as Bachelor of Applied Science and has since then held some very important positions, during a portion of the time being connected with the teaching staff of the University. He spent most of the years 1889 and 1890 studying and traveling in Europe and the United States, and on his return to Canada in 1891, he was appointed chemist of the Canadian Pacific Railway. From this position he resigned in 1896 to take up the general commercial chemistry and assaying, but still remains the consulting chemist of the Canadian Pacific Railway.

F. C. ARMSTRONG.

The Canadian General Electric Company is about to lose an important member of its agency staff in the person of F. C. Armstrong, who has resigned his position of general agent for that company to take up similar work with Dick, Kerr & Co., Limited, London, Eng., well known as a large engineering and contracting firm throughout Europe and the British Empire. Mr. Armstrong is a Canadian by birth. He commenced his education at Peterboro, Ont., with Dr. Tassie, and afterwards graduated from Toronto University. After leaving the university, in 1889, he engaged in electrical work and spent three years of those pioneer days as an electrical and engineering contractor. Since 1892 he has been in the employ of the Canadian General Electric Company, as chief of the agency staff, and during this time not only has he become favorably known to the public, but has obtained a broad technical and commercial knowledge, which no doubt will be of immense benefit to him in his new and larger sphere Mr. Armstrong has prepared at different times several papers for the meeting of the Electrical Association, and has also materially added to its success by his efforts as a member of the Executive Committee. While Mr. Armstrong's departure is to be regretted as being a loss to the country, yet he must be congratulated on the recognition of his marked ability and promotion to the important position which he will hold with Dick, Kerr & Co.

ELECTRICAL POWER TRANSMISSIONS.*

BY R. A. ROSS, E.E., M. CAN. SOC. C.E.

The subject of electric power transmissions over long distances has for the last few years been the field in which the most prominent electrical engineers have found a scope for their energies, and the advance in consequence has been most marked. So much so that, while four years ago there was not a power scheme of any magnitude, at the present they are numbered by the score, and are of such size as to utilize an immense amount of power formerly unavailable. A noteworthy point in modern plants is the similarity of the methods in use, especially in America, which is always more given to standardization than are European countries. The several types of alternating transmission have practically crystallized into two standard forms remarkably alike in detail and equally applicable to most cases. The controversies over the relative merits of direct and alternating current for transmission purposes have been settled, and the latter having come out victorious is now carrying the war into the hitherto undisputed territory of the former, namely, the application to general motor purposes, and the results are not doubtful. With the application of alternating current motors to traction purposes, which appears to be not far distant, the last territory held exclusively by the direct current will have been invaded. The reason for this state of things is not far to seek, as the alternating system which formerly was applicable only to incandescent light, has recently made such strides as to prove itself more generally useful for all purposes of transmission and for most cases of distribution than the other. This triumph of the alternating is due to the fact that with extremely simple and durable apparatus, the power is so readily transformed into that form which meets the requirements of most cases.

The efficiency and durability of the newer types of apparatus are such as to leave but scant room for improvement, and it appears probable that unless some fundamental discovery is made, which will render present types entirely obsolete, these forms will persist for some time to come. Accompanying this standardization of apparatus has come a remarkable decrease in first cost and maintenance charges affecting the interest and depreciation accounts correspondingly, and resulting in decreased cost of power to the consumer. In consequence we may expect to see the field of steam generation for many purposes invaded by the simpler, cheaper and more cleanly electric power. If we may judge by present indications, the next phase of the problem to be attacked will be the adaptation for railway purposes of power for large water falls. This only awaits the development of a satisfactory motor for alternating traction purposes, and, from the reports of several recent installations in Europe and the statements of prominent traction engineers in this country, the day of the alternating railway motor for use on the longer railways is not far distant.

To illustrate the methods adopted in transmission work, a few of the larger plants in operation or building are given below.

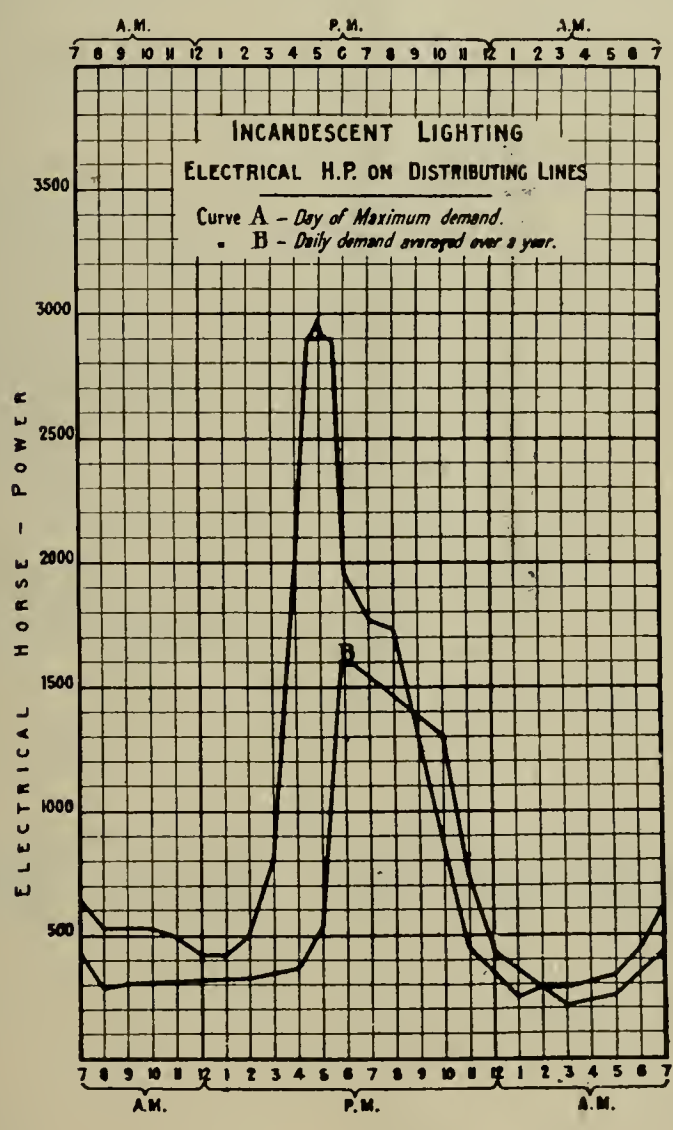
	System.	Distance.	Voltage.	Horse-power.
Brescia,	Direct cur.	12	15,000	700
Pomona,	Single phase.	29	10,000	800
Fresno,	Three phase.	35	11,000	1,400

*From a paper read before the Canadian Society of Civil Engineers.

Lauffen,	Three phase.	100	30,000	300	Experi-[mental
Portland	" "	12	6,000	5,000	
Ogden,	" "	38	16,000	3,000	
Three Rivers,	Two phase.	17	12,000	600	
Kootenay,	Three phase.		20,000	2,000	Building.
Hamilton,	Two phase.	38	20,000	3,000	"
Lachine,	Three phase.	5	4,400	20,000	
Chambly,	Two phase.	16	12,500	20,000	Building.

With one exception these are all alternating plants, and it will be noticed that Canada is well to the fore, as might be expected from the almost unlimited powers available. Montreal stands at the head of the world so far as transmitted power is concerned, and it appears probable that the two magnificent schemes at present under construction will find an ample market in the city and vicinity. Montreal's demands, covering as they do the whole field of consumption of power for street railway, incandescent and arc lighting, and motor power, offer a good example for illustrative purposes, and it has been deemed advisable to give point to the discussion to follow by reference to the demands existing in that city at the present time, without reference to future necessities, as these will no doubt be much of the same kind.

With this end in view, the following curves have been drawn, showing the demands for all classes of power at the present time for twenty-four hours.



The higher curve in each case shows the maximum demand during the year, and the lower the average load at each hour of the day for the year. From these demands the transmission scheme will be figured, but necessarily in a general way for illustrative purposes. The problem consists in laying down the power in the city to suit the demands in the most complete way as regards economy, efficiency and suitability. As these demands affect the transmission by their nature, as well as by their amount, they must be considered briefly before taking up the transmission proper.

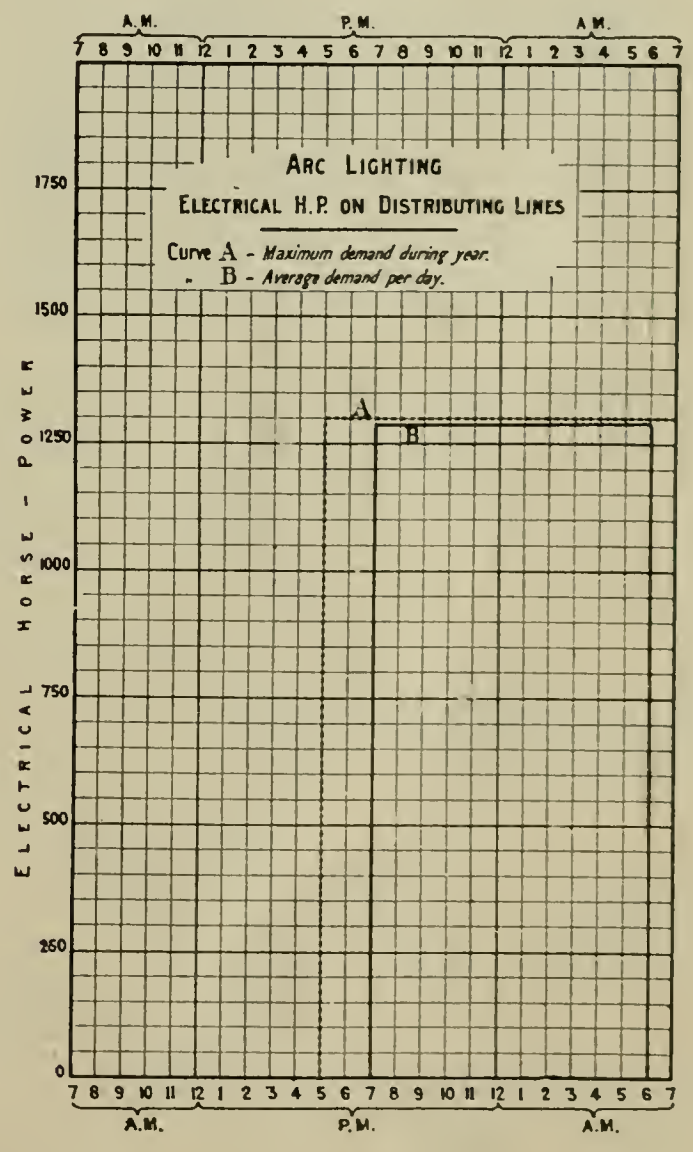
Incandescent Lighting.—The demand curves shown have been figured from the actual curves of one of the present stations in the city, with an allowance for the loads of the other operating companies; in all to cover 100,000 lights wired up. To meet this demand it will be readily granted that direct current is unsuitable, owing to the distances to be covered, and alternating currents of single, two or three phase are the only alternative, any of these being readily obtained from the transmission voltage by means of static transformers to feed the distribution at a voltage of say 2,000, which is considered safe for city work. This potential will of course be again reduced before entering customers' premises, thus involving two sets of transformers. This system will also cover interior lighting by alternating arc lamps, and perhaps a few small alternating motors.

The demand curves for the arc lighting have been figured on the supposition that there are 2,000 arc lamps on series circuits in the city, lighted from dusk to dawn, the curves in this case being elevated into straight lines. For this service several plans present themselves as below.

(1.) By rectifying the alternating transmission currents into direct through the agency of rectifiers, which are simply revolving commutators driven by small synchronous motors from the transmission line, and using this current in the present series arc lamp. This system has been in use for a short time in several European stations, with varying results. It appears to have a great future before it when it has come through the present doubtful stage.

(2.) By means of alternating arc lamps fed from the incandescent circuits. This system, while perfectly applicable for interior lighting, where each unit is treated as an incandescent lamp and turned on or off at will, is not so suitable for street lighting, as it does not lend itself to ready control from the station. Further, as the light distribution of alternating current lamps is inferior per watt of consumption to that of direct, it becomes more expensive in operation.

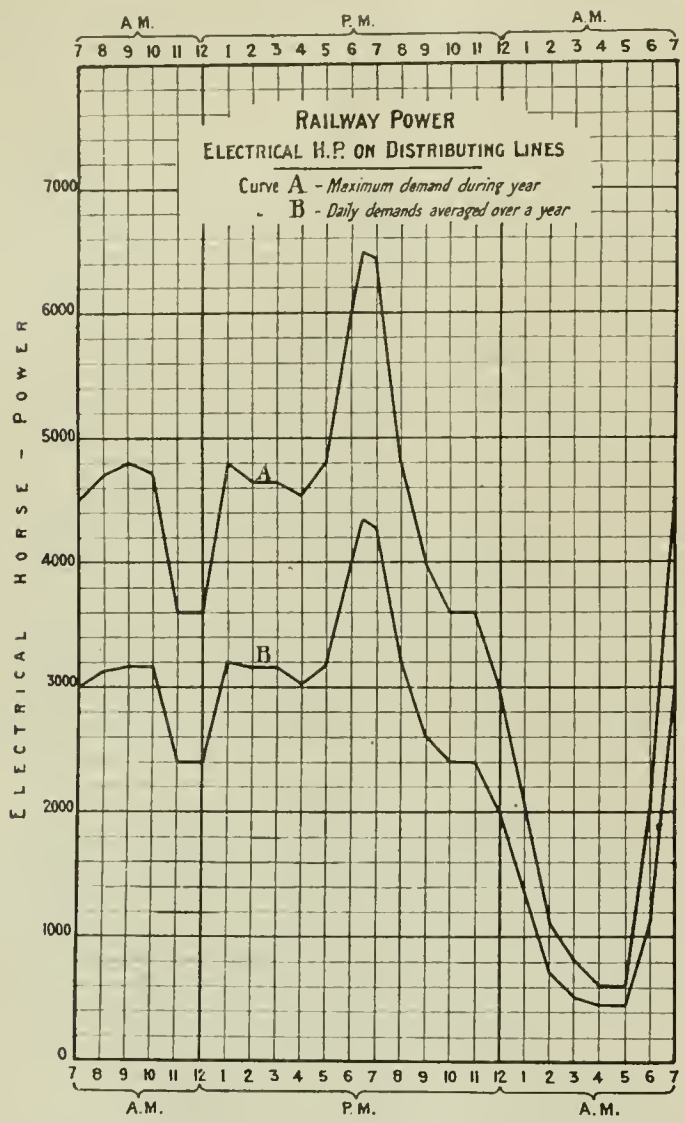
(3.) The series arc system as at present used, with motors instead of engines to drive the dynamos, while necessitating more apparatus than either of the others, is more simple and controllable in operation, and will be accepted for illustration. The number of units necessary to cover the 2,000 lights will be 16 if of 125 lights each, which is about as high as is available per machine. If these were coupled in pairs to 200 H. P. motors, the units would be eight, and the addition of a spare would make a total of nine, which would be ample for present demands.



Either alternating or direct current motors are suitable for general work, but, where variable speeds are necessary as for elevator purposes, the direct is at the present time the only one available. The cost of the former is also higher at the present time. The advantages of the alternating motor distribution are, less cost of circuits, greater simplicity of apparatus, and the ability of reaching outlying demands at small cost, and that it involves no special apparatus in the distributing station other than the necessary lowering transformers. As the objections to

the alternating (on the score of price and unsuitability where speed regulation is required) appear to be within reach of correction in the near future, that method will be adopted for this case. The demand curves are based upon the actual load curves of one of the present stations, with allowance for the other operating companies' loads. In all it represents about 1,100 H.P. of motors installed, to be driven from a two or three phase motor circuit, fed directly through reducing transformers from the transmission line, at a voltage of say 2,000, and again reduced by individual transformers at the motors.

The curves shown in the accompanying figure are the actual records for the past year for the railway company's plant. As at the present time only direct current motors are applicable to this purpose, means must be adopted for transforming the alternating to direct current for the trolley circuit. This is easily



accomplished by means of rotary transformers with small loss. These rotaries are practically direct current generators, with collector rings through which the alternating current flows to the windings driving the machine as a motor, while from the commutator connected to the same windings the direct current, which has been commutated from the alternating, flows to the trolley line.

Monarch Babbitt Metal

Best Anti-Friction Metal for all Machinery Bearings.

WRITE FOR PRICES.

Manufactured Only by

The JAMES ROBERTSON CO., Limited

263-285 King Street West, TORONTO.

Telephones: 819, 1511 & 1292.

—The Jas. Robertson Mfg. Co. has issued a very finely illustrated catalogue of the various bath-room, closet and sink fittings which this firm places on the market. The company also manufactures lead pipe, saws, plumbing goods, brass plumbing goods, fence wire, solder wire, triangular bar solder, paint and varnishes, putty, shot and bullets. The nickel-plating plant operated by the firm is on a large scale.

—In the course of a recent address upon building stones by Prof. Julien, of Columbia College, New York, before the Mineralogica Section of the Franklin Institute, some interesting facts were brought out. Professor Julien is an authority on building stones, and an expert in the preparation of thin sections of rocks—sections so thin that they are transparent; and their structure can thus be readily seen under the microscope. On this occasion the thin sections were placed in an electric projecting microscope, and the enormously magnified images were thrown upon a screen. The light was polarized by interposing suitable prisms, and under these circumstances each particle composing the stone revealed itself by its shape and color. The mechanical structure, porosity, density, etc., of each variety of stone were shown, revealing the way in which aggregations of rock particles are sometimes loosely held together without orderly arrangement and with spaces between, sometimes dovetailed into each other, and sometimes cemented together into a homogeneous mass. In some of the sections, which were as thin as a sheet of tissue paper, bubbles of liquefied carbonic acid gas were observed in the cavities of the small crystals. This liquid is held in the stone under pressure, and not infrequently the heat of the electric light, or even of the hand, is sufficient to explode it, shattering the specimens. It was easy to perceive from these illustrations why some building stones will stand great compressive strains and may yet be unsuitable for buildings in these latitudes, while other stones, much weaker inherently, may possess greatly superior weathering qualities. The statement was made that no "weathering tests" of building stones worthy of the name have yet been made. It seems very necessary that this should be done.

EMPLOYMENT wanted with a municipal or sanitary engineer as assistant or inspector. Good colonial and home experience. Apply DUNN, P. O. Box 532, Cape Town, or care of Hills, 147 Bow Road, London, Eng.

McGILL UNIVERSITY

MONTREAL

CHAIR OF ELECTRICAL ENGINEERING

The Board of Governors is prepared to receive applications for the W. C. McDonald Chair of Electrical Engineering. Salary not less than $2,000 per annum. Applications, accompanied by any testimonials which candidates may desire to submit, should reach the undersigned on or before the 20th June next.

W. VAUGHAN,
Secretary, McGill University, Montreal.

TENDERS ARE ASKED FOR

Addressed to S J. CARTER, Secretary-Treasurer Andover (N.B.) Water Commissioners, for the

Excavation and laying of 2½ miles of 6-inch Water Main

AND

Construction of a Dam 80 feet long and 10 feet high

Plans and Specifications to be seen at the office of the Commissioners.

C. L. B. MILES, Engineer,
ANDOVER, N. B.

April 27th, 1898.

For Sale Cheap

A New 100 Kilowatt 125 Volt Multipolar, Direct Current Dynamo

Latest steel frame type, with iron clad armature.

A most complete set of Station Attachments. Suitable for Incandescent Lighting, with a capacity of 2,000 16-candle power lamps, or for power or electro-chemical purposes; has never been used only for a test.

For particulars apply to E. H. HILBORN, 74 Brunswick Avenue, Toronto, or to JOHN TOLMIE, Kincardine.

STREET PAVING MATERIALS.

BY J. J. BELL.

It is clear that the experimental stage has not yet been passed in determining what is the best material for street paving. So many points have to be considered—durability, facility of repair, noise, sanitation, cost, etc., that it is difficult to determine what material combines these qualities in the greatest degree. What is suitable for one kind of traffic may be unsuitable for another, what is a success in one climate may be totally unfitted for another, a cost which is possible on a great business thoroughfare, or a fashionable residential street, may be out of the question on the poorer streets, where property owners cannot afford an expensive pavement. A good deal has yet to be done in the way of experiment, and the material employed must vary according to local conditions.

Wood and stone are the two natural materials which suggest themselves for street paving. The noise produced by traffic over a stone pavement precludes its use on residential streets, except in the form of macadam, while wood, so far as used hitherto in this country, is not sufficiently durable for heavy traffic. There is, however, a growing tendency to go back to wood in European cities, especially Berlin, and it is said that before long three-fourths of London will be surfaced with this material. The wood employed there is the Australian jarrah, which has displaced all kinds of wood except Baltic fir, which it is rapidly driving out. Jarrah is an exceedingly hard wood and is said to be equal in wear to granite. It is impervious to moisture, and being a species of eucalyptus is antiseptic and therefore no objection can be urged to its use on sanitary grounds. Another Australian wood, karri, is second only to jarrah, and the Tasmanian blue gum has stood very satisfactory tests in Glasgow. Of course none of these woods are likely to come into use in America, as it would cost too much to import them, where other suitable material is so abundant.

The experience of cities on this continent seems to point to asphalt as the best all-round paving material, cost being the principal objection. Laid on concrete it is durable, clean and easily repaired, and heavy traffic seems to harden and consolidate it. It is liable to rot from water lying on it, but this may be overcome by giving the roadway sufficient crown to allow the water to run off freely and by substituting stone or other material for gutters next to the curb. Asphalt will not answer for track allowances or the strip close to the rails, where the jarring of the cars rapidly disintegrates it, but with granite blocks, or better still, so far as bicycle traffic is concerned, scoria or brick on the tracks, asphalt makes an almost ideal street. An objection is the tendency of horses or bicycles to slip. With a thin coating of ice or snow, or in muddy weather, they are liable to do so, but there are comparatively few days in the year when such conditions exist to an extent to cause inconvenience. An interesting test of the merits of different pavements for slip was made in London, England, some time ago, when a record of the accidents for 50 days showed asphalt 1,066, granite 719, wood 542. On streets of steep grade asphalt cannot be employed. In Halifax concrete is used on grades and asphalt on the level. In New York asphalt is being substituted for granite on some of the streets, the asphalt surface being laid over the granite just as it is, instead of removing it and putting down concrete foundations.

So far as sanitation is concerned, an interesting fact is stated with regard to Buffalo, N.Y., which has more asphalt pavement than any city in the world. It is asserted that since the introduction of asphalt the death rate has decreased, especially among children. This, if verified by the experience of other cities, should go far to encourage the use of asphalt.

Next to asphalt in favor as a permanent paving material, and rapidly winning its way, is brick. In Toronto it is somewhat cheaper than asphalt, and could a good vitrified brick be supplied at a reasonable figure it would come into general use in replacing the cedar blocks which were so extensively laid down some years ago and which have proved such a failure. Brick is somewhat noisy, but it is not so slippery as asphalt, and is easily repaired and durable. A section of brick pavement at the intersection of six streets in Richmond, Indiana, which has been down for six years, and subject to heavy traffic, has not cost a single cent for repairs, and looks as if it was good for six years more. Asphalt and brick are likely to be the two favorite paving materials for city streets in the future.

Macadam will always be employed more or less for

roadways. Heavy traffic cuts it up, but by the use of broad tires this difficulty may be obviated to a great extent. No matter how well constructed, the stones are liable to work out, and it is dusty or muddy according to the season. By the use of trap rock, instead of granite or limestone, the highest perfection of macadam may be attained. There is a large deposit of trap near St. Joseph's Island, on the north shore of Lake Huron, which costs little more than the expense of quarrying. An experiment in its use was made at Cleveland several years ago. Two miles of road was made in one of the parks, which has worn well. The foundation is crushed limestone ten inches deep, then eight inches of trap in three layers—coarse screenings, fine screenings and dust—all well rolled. The road cost $3.10, $3.19 and $3.65 per square yard according to grade. Trap is extensively used in Germany, where it has proved very satisfactory. There are extensive layers of trap rock on the St. Lawrence near Kingston, convenient for loading on vessels, and therefore easily available for use in cities situated on the great lakes.

A very unlikely material for paving has been employed in the vicinity of the stock yards in Philadelphia. It is supplied from a plant set up at Norfolk, Virginia, to manufacture the grass that grows in the salt water marshes into paving blocks. The grass is subjected to enormous pressure, and then cut by circular saws into blocks 5½ inches thick. These are treated in three tanks containing different kinds of oil, which renders the fiber supple. A wire helps to hold each block together. The pavement is said to be smooth, noiseless and free from slip. The most remarkable paving material which the readers of this journal probably ever heard of is molasses! In the process of sugar refining in the Southern States large quantities of molasses are produced, which is a waste material, sometimes difficult to get rid of. The head chemist of a refinery in Chimo, Cal., bethought him of a means to turn it to account, and he had a walk, 1,000 feet long, constructed of slabs of molasses mixed with sand. It dried quickly, became hard and was not affected by the sun. A slab two feet long and one foot wide was tested by being placed on supports for a couple of inches at each end. When struck with a heavy hammer it showed no sign of either cracking or bending.

As cost is a very important factor in paving, a statement is appended showing the approximate cost per square yard of the pavements in general use in Toronto. The relative cost will be much the same in other Canadian cities. The figures are for a roadway 24 feet wide:

Heavy asphalt, 6 inches concrete, 2½ inches asphalt	$2 70
Light asphalt, 4 inches concrete, 2 inches asphalt	2 30
Brick on 4 inches concrete	1 60
" on broken stone	1 45
" on gravel	1 30
Cedar block on 6 inches concrete	1 40
" on 6 inches gravel (wooden curb)	70
Macadam	1 20

THE WHITE SLAVES OF THE PASS.

That there is no slavery under the British flag has been our boast for two generations and we have looked not uncomplacently upon the people of the United States, who by law made all men free and equal, yet for many years bought and sold their fellowmen in the open market. It is no longer lawful for a man to sell himself into bondage, or his wife or children, to pay his debts, but in Canada we have discovered recently that men may be decoyed into the waste places of the earth and there forced to toil their lives out in misery at the pistol's mouth. We quote one paragraph from the voluminous report of the commission appointed by the Dominion Government to enquire into the subject: "We note some special facts, such as, for instance, the fainting of men on the works; the refusal on the part of teamsters, whose wagons were hardly loaded, to give a ride to wounded men, such as young Joseph Bourgignon and Theodore Lambert; some threats of Noble, one of the foremen, to kick them; the alleged bad treatment by the same foreman of men who had had difficulties with the company, and who were discharged one day after they had returned to work; the refusal of food generally to all men discharged or quitting work, and the hardship experienced on account of this, which caused one Weir, for instance, to faint, and others to feel very weak, three men having to subsist for a whole day on one onion; a pinch of salt refused to men leaving camp, which they asked for in order to salt fish they might catch with a fish-hook given them by one of the men. All this when they were at distances ranging from 70 to 150 miles from, and having to walk to McLeod, often having no money, and, even with money, being unable to obtain food, and having sometimes to rely on remnants thrown away on the road." We do not repeat the tale of horror which recites the death from most painful disease of men who passed their last hours under such conditions of exposure to hunger and cold that their companions who were in health could not have avoided freezing except by the most continuous exertions.

The president of the Canadian Pacific Railway when interviewed on the subject is reported to have said that the contractors could not provide feather beds for the laborers. When a public complaint was brought to the attention of Sir Wm. Van Horn's fellow-countrymen, that other great United States railway dictator, Jay Gould, he said, "The public be d——d." The question which should be considered by every thoughtful Canadian is whether we are governed according to the B.N.A. Act or the C.P.R.

SANITARY EXPERIMENTS AT COLOGNE, GERMANY.

BY W. M. WATSON.

The city of Cologne, Germany, reframed its plumbing and private drainage by-laws, some years since, to comply with the fashion of the times, ordering back-air vents on all fixtures, and also traps and breathers on the main line house drains, but, after giving them a few years' trial, it was proved that the advantages of the system were not equal to expectation, or even so good as the method previously employed, which was erecting the appliances with as much simplicity, coupled with good workmanship, as possible, and a short time since the city fathers appointed a committee, together with Herr Maniewski, the leading architect, and Herr Unna, the noted sanitary engineer, to make a thorough investigation of the whole system.

The committee erected sets of soil pipe and drains made from glass; they also had a variety of water-closets, traps and small waste pipes made from the same material, and fixed them to a temporary erection, consisting of three flats, in the most public place in the city. They also got permission to cut out and examine a number of the oldest back-air vents in the city. They had been in use several years. Having lately finished the investigation, their report has been published in detail in No. 4 and 5 of the Gesundheits Ingenieur for 1898, a German engineering journal, and as the experiments are of great importance, the report has been republished in the English-speaking papers. This report relates that all the old back-air pipes the investigation committee cut out were choked up with either grease or coffee grounds, or cobwebs, which would of course prove that the vents had been useless, on several

grounds: 1st, Because none of the traps to which they were attached could ever have been in danger of being siphoned, or the back-air pipes would have passed down air to break the vacuum in the waste pipe, and to relieve the draw or suction on the water seal of the traps, and if any air had ever passed down the vent pipes there would have been no cobwebs choking them. 2nd, That they create complications, expensive intricacies and obstructions, interfering with the smoothness of the waste water flow, and are liable to become blocked up with the most poisonous and dangerous part of the sewage, viz., the frothy scum odors.

In the experiments the committee noted the influences of the sewage and air on various sized soil pipes at various grades and inclinations, also in vertical and horizontal position, and studied various sized traps, back-air pipes and connections, and depths of water seals. The influences on the flow of sewage, when the soil pipe was extended through the roof and the end left full open; when only partly open; also when the head of the soil pipe was totally closed up, and when the heads of the soil pipes and the back-air pipes were enlarged in the usual way immediately before passing through the roof. Also the action and influences on the private drains when main line traps and breather pipes were used. They found that a solid piston or column of water was only formed when the waste water from the fixtures was passing through inclined and horizontal pipes. And we know that when a piston is formed that there will be a suction of air or a vacuum behind the column that would siphon the trap or a number of traps, under certain conditions; but as such conditions never occur when the plumbing is installed by a competent person and used properly and in an ordinary way, it is a waste of money and is contrary to sanitary science to use back-air vent pipes.

They appear also to have proved that there is a limit to the pressure of the suction and the vacuums caused by water pistons, which can be overcome by arranging the plumbing so that no inclined branch can be longer than 39 inches, or by increasing the depth of seal in the traps, and by increasing the size of the waste pipes to about three times the capacity of the strainer or the mouth of the inlet. But our experience has proved that all risks can be avoided by making the branch from each fixture as short as possible, and branching them direct and almost level into a line of waste pipe that is extended through the roof, and the end left opened, so that the air can be drawn down when necessary. See illustration and full explanation in the issue of this journal for April, 1897.

The committee found that there was no advantage in increasing the size of the head of the soil or ventilation pipes as is customary at present, except it was possible to decrease the interior by hoar frost in winter, and this they were unable to demonstrate. When water was poured down one of the smaller fixtures it dashed against the opposite side of the vertical soil pipe, and at once resolved itself into fine, single threads, as if delivered from a sprinkler, and the number of threads increased in proportion to the amount of water poured down, until the bore of the soil pipe was entirely filled with thread, which acted as an air injector into the sewers and aerated the waste water passing down at the commencement of its flow towards the sewer mouth. In order to gain a knowledge of the amount of air sucked into the soil pipe an anemometer was carefully fixed on the mouth of the soil pipe above the roof, and one bucket of water was poured down a fixture when the anemometer showed that three cubic feet of air had passed down, and when four pailfulls were rapidly discharged down a fixture there were 17¾ cubic feet of air carried down with the water. Supposing the four pails held two cubic feet then it would prove that the water carried over eight times its own bulk of air with it down the soil pipe into the drains. When water was poured in at the top of the vertical soil pipe the moisture of air sucked in was only half the amount that was drawn in when discharged into the soil pipe through a branch. When the head of the soil pipe was partly closed the number of threads was reduced proportionately, and the seals of the traps showed signs of agitation, and when the top of the soil pipe was closed altogether and the four buckets of water were poured down quickly the water did not break up in threads, but formed a piston which siphoned the traps of all the fixtures except those that branched into a secondary line of waste pipe that had an open end above the roof. When the sewage was flowing through the horizontal sewer it formed a concave surface which largely increased friction and reduced the speed.

When any of the small waste pipes were extended at the upper end and the end left open so that air could pass down when required, the same result was obtained as when experimenting on the soil pipe.

It was shown that when a main interception trap was used, that it not only modified the speed and partly obstructed the flow of sewage, but it prevented any of the air carried down by the soil and other waste water pipes from discharging into the street sewer where its aerating functions are so necessary to commence the purification of the sewage in the drains and assisting in preventing sewer gases generating in the sewers. It was also shown that when the main interception trap is omitted there is a superior and self-cleansing flow of sewage, and that large volumes of air pass forward to the street sewer, creating a healthy atmosphere and circulation of air down the soil pipe through which the fluid is passing, and up other soil pipes that are at the time standing idle.

These experiments, especially those that show that air is carried down with waste waters and that the main trap is a dangerous obstruction, fully explain the reasons why those towns that do not use back air pipes and that extend their soil pipes from the crown of the drains to the highest point of the roof and which make every rain water leader and waste water pipe to pass to the street sewer without any obstructing trap or sharp angles or interruptions of any kind, are almost free from odors in the houses and streets, and free from diseases that can be traced to sewer gas poisoning. While, on the other hand, those cities which have adopted the principle of interception traps, back air ventilation pipes, with all their intricate complications, are often quite the reverse, and of disease a great deal is found among the inhabitants who happen to live in the modern built houses where the obstruction system has been installed. And this is in spite of the fact that the same towns often spend large sums of money in flushing drains and artificially ventilating the street sewers, a thing which is never necessary if the sewers are laid down properly and the straight unobstructed system is adopted. The city of Cologne has now had enough of the complicated system of plumbing and draining and in future will avoid such expensive luxuries and again allow their sewage water to leave inhabited premises with as much expedition as possible, and secure all the aeration it can throughout the journey to the outfall, without making itself a nuisance to the public.

The Cologne investigation has a bearing on sewage purification. It will be remembered that more than twenty years ago Dr. Pasteur, of Paris, and Dr. Warrington

declared that sewage contained the necessary organisms for its own purification. Dibdin, of London, England, has shown us the way to compel sewage to clean and purify itself. Adney, of Dublin, has proved that domestic sewage requires three times its own bulk of air regularly and evenly supplied and distributed to every particle or atom of the sewage to enable the friendly bacteria to destroy the poisons, etc., the sewage contains. Lowcock, Birmingham, has shown us a method of applying the atmospheric air to the sewage, and Reid, of Staffordshire, recommends that all sewage should be purified while fresh before putrefaction sets in or sewer gas begins to generate The fathers of the city of Cologne have shown us by their experiments that the sewage will split up into fine threads of spray and take up atmospheric air in larger quantities even than Adney tells us is needed during the time it is falling vertically down the waste pipes. Therefore the bacteria can secure all the oxygen needed for a short period and when the sewage is in a fresh state. If every house rain water leader and waste water pipe were made to form a street sewer ventilator, and the water coming down each of the pipes will bring down four times its own bulk of air, which will go a long way towards providing all the air that is needed to do the necessary work of cleaning the sewage, and in that case the public sewers will be changed from a gas generating chamber to a receptacle for the aeration and purification of sewage and dirty filters, in that case they would be harmless. While under obstructive plumbing by-laws and private drain arrangement of interception traps, no aeration of the sewers can take place, therefore putrefaction immediately sets up and sewer gas is generated abundantly, which poisons the dwellings and the atmosphere of dense populated towns.

The Cologne investigation has demonstrated that most sanitary appliances can and ought to be made of glass, that all soil pipes and lines of waste water pipes should finish with an opening outside, that no rain water leader should join to soil or waste pipe until it reaches a point below the inlet of the last branch pipe coming from the lowest sanitary fixture.

The German scientists are reliable, and their experiments and judgments can be acted upon with safety, and the expensive experiments they have made may be freely taken advantage of by other towns.

THE QUEEN CITY OIL COMPANY.

The location of business houses in Toronto has been undergoing considerable change of late years, and the tendency of trade has been towards concentrating on Yonge street, as near King as possible. Among other well known firms which have moved with the times is the Queen City Oil Co., which has just transferred its extensive business from 30 Front street east to the handsome new Lawlor Building, corner King and Yonge streets, Toronto. The offices occupy the whole of the flat, a dimension of 60 x 90 feet, with 14-foot walls, and are the finest in Toronto for ventilation, light and convenience. They will be occupied by a staff of twenty-five, the hands employed in Toronto, the headquarters, numbering about 200.

The phenomenal progress made by this organization during its history of nearly a quarter of a century is largely due to the tireless energy, conspicuous business ability and unswerving integrity of Samuel Rogers, the founder and present manager of the company. When Mr. Rogers started in the oil business in 1876, he found difficulties confronting him in every quarter. But armed with an iron will, and a resolve to be second to none, he overcame the obstacles one by one. From the very first he determined to encourage Canadian industry, and he has resolutely persevered in that course, to the advantage of the people at large, as well as of the large force of men in his employ.

With the firm, Fairbank, Rogers & Co., he opened a refinery at Petrolia, which has since been merged into the refinery at Sarnia, now the largest in Canada. Although he is now over sixty years of age Mr. Rogers has not relaxed his efforts in one particular, and he is still the central moving spirit in the large and successful company of which he is the founder. He has now associated with him in the company his two sons, Albert S. Rogers, secretary and treasurer of the company, and Joseph P. Rogers, manager of the lubricating department.

The Queen City Oil Company, besides the works on Princess street, Toronto, has branches established in all of the principal towns in Ontario, and sells in Canada the products of the Standard Oil Company. By care in treating the oils they have been able to furnish a product at least equal to the best American oils, and the company has gained the confidence of the public wherever its goods have been offered. The various oils are too well known to need extended mention, Among the best known are the Sarnia White Burning Oil, and the Peerless Oil for farmers' use, one of the best lubricating oils on the market.

Altogether Mr. Rogers is to be congratulated upon the success which has crowned his labors during the past quarter of a century.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports of interest to the metal trade from Great Britain during May and the four months ending May, 1897, 1898:—

	Month of May.		Five months ending May.	
	1897.	1898.	1897.	1898.
Hardware and cutlery	£7,730	£2,131	£25,647	£10,243
Pig iron	563	569	1,018	5 793
Bar, etc.	316	1,143	4,205	5,110
Railroad	6,935	..	20,286	6,972
Hoops, sheets, etc.	5,436	6,122	16 445	11,592
Galvanized sheets	3,975	6,909	15,998	20,980
Tin plates	8 652	21,423	80 972	61,968
Cast, wrought, etc., iron	3,880	3,408	14,965	13,658
Old (for re-manufacture)	.. ..	606	572	1,504
Steel	3 493	4,877	18,480	24,298
Lead	1,672	3,745	4,454	8,050
Tin, unwrought	1,609	3,157	8,923	9,087
Alkali	3,533	5,179	11,722	16,737
Cement	1 825	2,771	4,778	8,262

SEWAGE DISPOSAL.

Editor CANADIAN ENGINEER:

My attention has been drawn to a letter published in the June issue of the CANADIAN ENGINEER signed by "Expert," which is false, malicious and libelous in its statements. I hereby ask "Expert" to be manly enough to come out in his own name and repeat his statements so that I may have an opportunity to meet him in the open; I will not brand him as a coward yet until we see whether or not he will have the manliness to sign his own name as requested.

Yours respectfully,

JOHN MACDOUGALL.

635 Cass Ave., Detroit, Mich., June 22nd, 1898.

Editor CANADIAN ENGINEER:

There is an article in the June issue of your valuable periodical signed by "Expert," which contains misrepresentations of the sewage and garbage disposal processes mentioned therein which I consider to be injurious to the Company represented by John Macdougall, therefore, in justice to that company, provided his statements are true, the writer of the article should have had the manliness to sign his own name instead of a nom de plume. My knowledge of the International processes of sewage disposal and of Warner's garbage destructor, which has been obtained from a long period of study of such subjects, as well as from a personal examination of many works of that character in Great Britain last year, has compelled me to arrive at but one conclusion, namely, that the above-mentioned processes for the disposal of sewage and for the destruction of garbage have no equal either in Europe or America for efficiency and economy in their operations, and I am backed up in that opinion by many of the leading sanitary scientists in those countries, especially in Great Britain. Let "Expert" come out like an honest man under his own name, which he should do if his statements are true.

Yours very respectfully,

J. A. SMITH.

Windsor, Ont., June 27th, 1898.

THE CANADIAN ELECTRICAL ASSOCIATION, PHOTOGRAPH TAKEN ON THE DAM OF THE CHAMBLY MANUFACTURING COMPANY.

CANADIAN ELECTRICAL ASSOCIATION.

EIGHTH ANNUAL CONVENTION.

The eighth convention of the Canadian Electrical Association was held in the Windsor Hotel, Montreal, on the 28th, 29th and 30th June. On the first day, the meeting, which was the best attended in the history of the association, was called to order by the president, John Yale, manager of the Guelph Light & Power Co., shortly after 10 o'clock. After the reading of the minutes of the last meeting by the secretary, C. H. Mortimer, Mayor Prefontaine, of Montreal, was introduced, and welcomed the convention to Montreal. The president said that all were pleased to receive the greeting of the Mayor of Montreal, and called upon A. A. Wright, of Renfrew, to support him in his statement, which he did in a neat three minutes' speech.

The president then read his address as follows: "I beg to give you all a hearty welcome to this the 8th convention of the Canadian Electrical Association. The aim of the association is to gather together the members of the Electrical Fraternity, and allied interests for the purpose of mutual discussion, and to learn from each other's experience. In this way we try to benefit the whole business interests with which we are all connected. An organization of this kind confers upon its members benefits from the reading of papers, and the discussions which take place disseminate information with reference to the methods that are constantly being tried by different members in the practical conduct of their everyday operations and business methods. This association affords the means for members to become acquainted with one another. The friendships here formed should be used for the purpose of mutual protection and advice when difficulties arise. A free and friendly correspondence tends very much to strengthen, stimulate and encourage many of us in our daily struggle with difficulties. It is a matter of satisfaction to me that during the last two years you have honored me with the office of president, good progress has been made in the direction indicated; but there is still room for great improvement.

It is now almost four years since the last meeting of the Canadian Electrical Association was held in the City of Montreal. During the interval conventions have been held once in Ottawa, twice in Toronto, and last year at Niagara Falls. On each occasion matters of current interest and importance have been presented for the consideration of our members. There are many reasons why our meeting, again this year in the east, and particularly in Montreal, should be at once a source of both pleasure and profit to the members of this association. The intervening four years have done much for the Dominion of Canada, for its national life and the development of its material resources. In no department of industry has this progress been more marked than in the electrical field, in electric lighting, in electric railway work, and in the electric transmission of power; and the work must not be forgotten which has been done in extending the use and improving the service in the older branches, the telegraph and the telephone. From this development of the great modern industry in which we are all proud to have a share, no part of the country is likely to reap greater benefits than the City of Montreal and its vicinity.

The Dominion of Canada, at least, so far as Ontario and Quebec are concerned, while otherwise abundantly dowered with mineral riches, has been deprived of coal deposits, until recently an essential factor in manufacturing and industrial development. To-day, however, the possibilities of electrical transmission have rendered available as a substitute to turn the wheels of our factories, the heritage which both provinces possess in their abundant water powers. It will be our privilege to inspect what has been done in this direction by some of her far-sighted and enterprising citizens for the City of Montreal. We shall first see that great enterprise, carried out in the face of difficulties and discouragements, the successful utilization of the power of the St. Lawrence river by the plant of the Lachine Rapids Hydraulic and Land Company. Of equal interest and importance will be the opportunity given of inspecting the plant and equipment of the Chambly Manufacturing Company on the Richelieu river at Chambly, which will vie with its great rival in the beneficent work of supplying cheap light and cheap power for the citizens of Montreal. It is to be hoped that a fair dividend will be the reward of the shareholders of the two companies for their enterprise. It is proper, before entering on the work of this convention, we should glance briefly over the progress of the past year. A marked feature of electric progress in the Dominion throughout the years 1897 and 1898 has been the inception, and, in some cases, the completion of a number of important plants for the long distance transmission of power. In the Province of Quebec there are besides the two plants already mentioned, the Montmorency plant, which has been in operation for several years, and is no doubt familiar to most of you, and the North Shore Power Company, Three Rivers, a 16 mile transmission, 12,000 volts, delivering 500 k.w. In Ontario there is the Cataract Power Company of Hamilton, the distance to be transmitted 33 miles, pressure 25,000 volts with a capacity of 6,000 h.p. This plant, it is anticipated, will be in operation by August 1st next. In British Columbia a transmission installation of 1,500 h.p. capacity is being erected to supply energy for the Electric Railway, lighting and power industries of the City of Victoria, distance 16 miles. The West Kootenay Power Company recently started with an initial capacity of 2,000 h.p., pressure 20,000 volts, distance 30 miles. This power will be used for the operation of machinery in the mining districts. We have already referred to the enormous development under way in the vicinity of Montreal.

The only point at which satisfactory progress cannot be reported is at Niagara Falls, where, unfortunately, the tying up of the greatest water power in the Dominion in the hands of an alien corporation has prevented its development for the benefit of the people of Ontario. This state of affairs, we trust, will be removed before another year. Besides the important plants mentioned which are either in operation, or in course of construction, a large number of similar enterprises are at present in their initial stages and may be expected to reach their completion within the next year or two. Altogether, it is difficult to foresee at the present moment the benefits which our Canadian manufactories and industries generally may derive from the utilizing of the water powers of the country, scattered without number from the Atlantic to the Pacific. In electric railway work the development of the year has been mainly confined to the extension and the better equipment of existing city and suburban roads.

In the field of electric lighting, in which a majority of the members of the association are more particularly interested, a reasonably satisfactory condition of affairs exists. That industry is on a fairly solid basis, at least, in so far as a distribution of current for incandescent and power purposes is concerned, as rendered evident by the failure of the much-talked-of illuminant of the future, acetylene gas, to make any inroad into the field of the lighting companies. A large majority of the plants now in operation are equipped with reasonably modern and efficient machinery, and the rates at which current is supplied are, it is safe to say, if taken on the average, the lowest in the world.

We will have before us the report of the Committee on Legislation. From this you will see how far the efforts made since our last meeting have been successful in the direction of securing equitable protection of private investments. It is to be hoped that the work of the association during the convention will be helpful to the members and that they will recognize the value they receive from their attendance here with respect to the papers which have been prepared for the convention. You will see their practical and helpful nature, and I trust you are ready to criticize and discuss the views set forth in the light of your own experience. One thing more I feel should be mentioned, and that is, the appreciation of the efforts of the different companies and individuals in Montreal who have so heartily co-operated for the success of this meeting. The proverbial hospitality of our metropolitan city is known to you all. A pleasing feature at our last convention, was the regular and prompt attendance of members at all sessions and the keen interest taken in the proceedings. This commendable practice will, I trust, be kept up at this our eighth convention, now open for business.

The president then nominated B. H. Reesor, Lindsay; A. B. Smith, Toronto, and C. B. Hunt, London, as a committee to suggest the names of the Standing Committees.

A. A. Wright, of Renfrew, then read his paper on "How to Overcome Some of the Difficulties Encountered by Central Station Men."

HOW TO OVERCOME SOME OF THE DIFFICULTIES ENCOUNTERED BY CENTRAL STATION MEN.

BY A. A. WRIGHT, RENFREW, ONT.

In treating this subject I shall do so from the standpoint of one who has to deal with customers living in a town of moderate size, and not from that of the owner of a plant in a large and populous city, because the circumstances would be, in many respects, quite different, and the requirements, as well as the mode of arranging the service, would be altogether different. I shall take it for granted that the central station is equipped with an arc and incandescent plant, that the proprietor not only does commercial lighting, but supplies light to the corporation as well.

1st. Let us take up arc lighting on the street. This brings us at once into contact with the corporate fathers, many of whom know nothing of arc lighting, except that it is not only necessary, but their special duty, to appear wise in order that they may look well after the interests of the town.

And now let me make my first suggestion, and that is, that you leave municipal politics entirely alone. If you have an inordinate craving after politics, which you have not the power to restrain, let your light shine before the throne of the Legislative Assembly or in the chamber of the House of Commons, but restrain yourself from meddling with municipal politics, lest you make to yourself enemies who will be sure to avenge themselves, sooner or later, in crippling your lighting contracts with the corporation. I do not wish you to infer from this that you should not exercise your franchise when the day for voting comes around, but on the contrary, let it be known that you and your employees always vote for the progressive and enterprising men of the town, and as every aspiring alderman will want your assistance, you if you do not make too much noise, will generally manage when he is elected to get his. Be careful not to make political enemies but to have as many of the town authorities with you as you possibly can. In most towns the contracts for street lighting are made annually, and not as in cities, for a term of years. See to it then, that your contract is so arranged that it shall terminate on the 1st of March. You can do this by informing the proper authorities that your books are so arranged that your Electric Light year begins on that date. Then see that the following harmless looking saving clause is inserted near the closing part of the contract. "And it is further agreed that either party may terminate this lease at the end of its term by giving the other thirty days' notice in writing prior thereto, and in default of such notice this agreement shall continue in force after the termination thereof, for one year, and upon the same terms and conditions as are herein expressed, and in like manner thereafter, unless such notice is given at least thirty days before the corresponding date in each succeeding year, a like renewal and extension of this lease from year to year shall be considered as made and executed by and between, the parties hereto." Furthermore have your payments fall due quarterly and on the 1st of March, June, September, and December. You know that in Ontario at least, our municipal elections are held at the beginning of the year, and as most of the aldermen will be aspiring to re-election, and would like to have your assistance to re-elect them, they will quite naturally forget, as the term of their holding office is drawing to a close, to give notice of the desirability of terminating that contract, and you almost invariably escape that threatened danger from the outgoing council. Then the new council does not assemble till the last of January and as very little business is done at the first meeting and many of the members are new ones, Electric Lighting is not thought of till your quarterly account is presented in March, when it will be too late to give the required notice, and so your contract runs on in this manner from year to year, renewing itself without any trouble whatever. Another difficulty, which you are almost sure to encounter, is the height of the poles on which your lights are placed on the streets. Some will want 50 ft. poles some 75 ft. and some even higher than either of these. When your contract is made be sure and have the clause worded in this way. "That the hangers from which the lamps are suspended shall be——feet from the natural level of the surface of the ground at the foot of the pole," and not, that the lamp shall be so many feet high, as you will notice that this makes an important difference in your favor. It is well to have it so arranged that you need not run your arc plant on moonlight nights, not merely on account of the direct saving that there is in this, but it sometimes is very convenient, if there are accidents, in giving you an opportunity to make needed repairs.

And now as to your commercial lights. Have your contracts made with your customers on a yearly basis, with same renewing clause that there is in your contract with the town, but with this difference, that the payments in this case be made to you weekly, and then see to it that you make your collections in this way, for a man will frequently pay you a small sum weekly, when he would not pay the same amount if paid quarterly. It may not be amiss to mention that in all these contracts, when stating the candle power of the lamps you are to furnish, that you should be sure and employ the words "nominal candle" power, as it may save you, under certain circumstances, no small amount of trouble also

And next, as to your incandescent service. This will, of course, be largely, if not entirely, a commercial service. You will have all manner of people to deal with and you may expect, in many cases, to have your patience sorely tried.

Then to begin at the beginning. Never under any circumstances do free wiring. By that I mean that you should never undertake to wire a house for nothing, in order that you might thus get a customer for your current. Of course you should do all primary work as low as possible, but not at a loss If your power is at all limited or if you run by steam, you will find, in my opinion, that you will make more by running your lights on the meter system than you will by giving a flat rate, unless you get an exceptionally good price for them.

I understand that in many places it is customary to take the readings of your meters quarterly, as it thus saves a good deal of time in taking the readings, making out the accounts collecting them, etc. In this, as in other things the old adage holds good that "Short accounts make long friends" and by no means should you allow your accounts to pass more than one month without being rendered and if possible collected It might not be so bad, in the short nights of midsummer if quarterly collections were adopted but in the end it will amply repay you to take your readings on the first day of each month, and make your collections on the 2nd.

And now as to the location of your meters. We were instructed when installing our plant to locate them in some out-of-the-way place, where they would not be seen, and high up, so that they would not be meddled with. Now this may all be very good advice in its way, but my advice to you is, not of course to put it in the parlor, or in such a place as to cause it to be an objectionable feature in the household, but, be sure and place it low enough that your man can get at it with as little trouble as possible, and also in a place where there is an abundance of light, so that the readings may not only be taken quickly, but accurately. When you have a large number of readings taken monthly, it becomes a matter of some moment that meters be so arranged that the work can be done quickly and accurately as well. You will be frequently told by your customers that the meter is wrong—that they know they never burned that amount of current. In such pronounced cases as these, when the assertions are very strong, I find it is better at once to say, "Well, it is possible as you say that there is something wrong; you know we are none of us infallible; we will see and have a second reading made at once," and look into the matter and at once, do as you have promised, no matter though you feel almost sure that it is all right. You may find that there is an error, and if so you should of course immediately see that it is corrected, but if you find that the reading is correct, and that Mrs. Julius Caesar still insists that that meter is no good, and declares that the thing runs whether there are any lamps on or not, and tells you in a most emphatic manner that she can hear the thing sing like a rattlesnake, lights or no lights, and she knows that it runs on wheels, what then? Above all things do not allow yourself to answer back harshly, for doubtless she really is sincere in her protestations, and it is not wise to contradict her too rashly. I have found a good remedy in replying that of course it is just possible that the meter is not absolutely correct, but that you feel quite confident that it is, and that to cover just such cases as these the government has appointed an electrical expert, to whom both parties can appeal, and if she, after considering the matter over, still thinks there is something wrong, that you will write and have the inspector come up and examine the meter, and if he finds it wrong, that you will bear all the expenses connected with the inspection, but if it is correct that she is to bear all expenses. Tell her just to think the matter over and let you know, and so far as my experience goes that ends the matter.

Another difficulty that you will doubtless meet when running on the meter system is in having your customers send out of town for 5 c.p. lamps and when only one of these is used your meter will not respond. This you will easily discern when at the end of the month you perceive that no current has been consumed, and I may just here mention that this is another reason for taking your readings monthly instead of quarterly. Such cases are not numerous, yet they do turn up where the family is small and its members are contented to do with a minimum of light. This difficulty can also largely be overcome by making a minimum rate of say 50 or 75 cents per month, which amount can be arranged according as the circumstances of the case may require.

There are of course many other difficulties that central station men have to deal with, but it is impossible to consider many in an article of ordinary length, and the remaining ones will be left for others to treat with, as they, in their wisdom, may see fit.

J. F. H. Wyse, Brantford, said he had been much interested in the paper. He had recently been through the mill in dealings with the Brantford, Ont., municipal authorities. He found the sending of notices, the third being an intimation that the supply would be cut off by a specified time unless dues were paid, was a very effective method of dealing with slow payers. C. B. Hunt, A. A. Wright, B. H. Reesor and A. B. Smith followed in much the same strain. C. B. Hunt then moved and A. B. Smith seconded, a vote of thanks to the reader of the paper and the meeting adjourned.

The members reassembled in the afternoon at 2 o'clock when W. H. Browne, manager of the Royal Electric Co., Montreal, read Louis DeWitt Magie's paper on the "Electric Utilization of Water Powers."

ELECTRIC UTILIZATION OF WATER POWERS.

By L. D. W. Magie.

The utilization of power going to waste in fast running streams has commanded for many centuries the attention of mankind. Regarded, on the whole, as "wasted energy" and as power that could be obtained "for nothing," the question of how to make it useful perplexed our forefathers, and is still giving us some study to-day. Although it would appear that, during the reign of Augustus, about 40 A. D., the first water wheels were made and used by the Romans, the scientific development of the water wheel appears to have been left until the present era, for until within the last few years, comparatively, the only devices used to convert the kinetic energy of streams into effective mechanical energy were the various forms of undershot and overshot wheels Crude as were these instruments, they have played a most important part in the world's history, for they have done much to develop countries with natural resources. Manufacturers who sought cheap power adopted the "wheels" available and located their plants along favorable streams, where these crude transformers of energy were made to grind corn, saw wood, make cloth, etc. The inventors of the present century awakened to the necessity of improvement and have provided the present types of wheels. To their higher perfection and adaptability is due the fact that almost every power producing stream in settled districts of the civilized world is utilized.

The harnessing of water powers is not an easy task, but requires a great deal of thought, scheming, trying and fitting by the engineer. The records of the stream have to be looked up and studied into, with reference to high and low water, during a period covering many years, and due provision made for getting rid of the maximum flood of every season. The possible storage capacity must be looked after, for oftentimes by a little forethought and a comparatively slight additional expenditure, a stream that naturally gets very dry at certain seasons can be made, by properly arranged storage, to give a practically constant output the year round. Again, by carefully arranging the surrounding conditions, a stream may be made to give for a comparatively short period, when power may especially demand, double or triple its normal output capacity. Probably one of the most important things to study, especially in localities subject to severe winters, is the question of frazile or anchor ice. This is a condition which has caused hundreds of thousands of dollars to be spent, either from the lack of knowledge or want of forethought; in some cases the conditions have been such as to make it almost impossible to successfully cope with them, without expending such sums of money as to practically ruin the enterprise. To overcome it successfully, the only way seems to be to provide a large pond of still water, extending to as great a distance as possible, even several miles, if attainable. Many other details must also be studied before determining the best location of the water motor power house, so as to obtain the greatest available head with the least expenditure. In the study of the question the natural conditions of the soil, water and climate, all have an important bearing, on not only the engineering success, but also on the financial success of the enterprise.

As waterfalls cannot themselves be moved from one place to another, manufacturers have had to locate the sites of their plants at the falls. In many cases it is necessary, and in nearly every instance very desirable, that the power be transmitted to a certain distance. When the distance has been comparatively short it has been accomplished by belting, gears and line shafts, but when the distance extends beyond a few hundred feet, this system becomes so inefficient, expensive or impracticable, that some other way has to be found. Rope transmission has been used quite successfully, even to a distance of a mile, and in a few instances over that distance, but as the best practical efficiency is not over 60 per cent., and the first cost, as well as maintenance, is usually very high, this system has not yet been so successful as to command its adoption very extensively. Compressed air has also been used for the transmission of energy with some success, more particularly in Paris, where there is a large plant still in existence; but here again the engineering cost has been great, efficiencies low, and maintenance high, and consequently, like the rope transmission system, has not met with general use and practice. The electric dynamo and motor have given an entirely different aspect to the transmission of energy. Although invented in the early part of this

century, it is, however, only within the last few years that the electric dynamo and motor have been developed practically and commercially. The success and high efficiency attained by electric transmission of energy is such that the "waterfall" is gaining prominence as a source of energy.

The pioneer work in electrical transmission was done with direct current system, and too much credit cannot be given for achievements attained. However, although in a few instances the distance transmittted by the direct current system has been up to twelve miles, yet, on the whole, for commercial reasons it has not been desirable to transmit power by direct current to a distance of over two miles, and even the advisability of this is looked upon to-day doubtfully. The reason for this is not because of the inability to transmit the power effectively, but because of the inadaptability of direct current apparatus for use at high voltages. The construction of direct current machines is such, having, as they do, so many auxiliary parts, that at high voltages they are very liable to break down, especially at the commutator and armature cores, except with very costly construction, and even then they are not at all sure; at high voltages the brushes are liable to spark and cause trouble at the commutator; and as the high tension parts require continual attention and adjustment while the machines are in motion, they are dangerous to the attendants. Probably, however, one of the most important reasons for the inadaptability of direct current machines for long distance transmission at high voltages, is the inability to reduce the voltage to that at which it would be safe to operate at the place of consumption without the use of expensive and cumbersome as well as inefficient banks of motors. Such motors of high voltages, having parts under high tension which require attention and adjustment while in motion, could not or rather should not be used except under the care of expensive special experts in every separate mill or factory where such motors were installed. To place them in the care of uneducated men would be unwise, and, in fact, foolhardy. The highest voltage that D. C. apparatus can be wound for, commercially and safely, seems to be, as universally adopted, from 500 to 600 volts. The reason that power at this voltage cannot be transmitted great distances is purely a commercial one. There is no electrical reason why power by the means of direct current might not be transmitted to an indefinite distance, entirely effectively and successfully. The amount of copper required for the transmission of power is directly proportionate to the amount of power to be transmitted, and also directly proportionate to the square of the distance for a given efficiency. This may be stated commercially by the amount of copper required for transmitting, say, 100 h.p. for both one and ten miles, the loss in transmission to be 8 per cent. and the voltage to be 500 volts. For each leg of a one mile circuit there would be required two No. 0000 wires, or four No. 0000 wires, each one mile long, weighing 15,312 pounds, which at 15 cents per pound would cost $2,300. For each leg of the ten mile line there would be required twenty No. 0000 wires or forty No. 0000 wires, each ten miles long, weighing 1,531,200 pounds, which at 15 cents per pound would cost $230,000; or the power would cost, at 10 per cent. interest and depreciation on copper alone, $2.30 per h.p. annum in the first instance, and $230 per h.p. annum in the second case. If, however, the voltage be raised to 5,000 volts, and be used for transmitting 100 h.p. for ten miles, the condition would be entirely different, for instead of forty No. 0000 wires, each ten miles long, there would be required for each leg but one No. 4 or two No. 4 wires each ten miles long, weighing 15,300 pounds, which at 15 cents per pound would cost $2,300, or the same as transmitting the same amount of energy only one mile at 500 volts.

From the above it will be seen that the transmission of power at 500 volts is not entirely prohibitive for short distances, but as the distance increases it becomes one of vital importance, for the cost of copper is not the only item of expense then to be considered; the pole line itself becomes a very grave matter, especially when we have to consider the weight of forty No. 0000 wires, as in the example for only 100 h.p., and the cost becomes one that investors cannot afford, for the reason that power can be obtained cheaper from other sources, so that commercial transmission of power long distances by direct current at practical voltages is not practicable. Although, as stated before, considerably higher voltage than 500 volts has been used with some success, as at Brescia, the number of such plants are very few. It is a noteworthy fact that on this continent, where the transmission of energy is further advanced than anywhere else, there is not a single plant of any prominence that is transmitting energy by high tension direct current system. It may be interesting to know that three or four years ago, when the Chambly plant was first discussed, a European firm planned out and tendered for the construction of that plant for transmitting the energy by means of this high tension direct current system, but, for reasons as above discussed, that system was not adopted.

How to meet the problem of long distance transmission, commercially and efficiently, has been left almost entirely to the alternating current system. Alternating currents were known about the same time as direct currents, or about 1831, and were explained to the world by the great Faraday, who at that time discovered the elementary principles. From that time on, experiments were made by different inventors on induction coils, but no material progress was attained until May 22nd, 1877, when Jablochkoff obtained British patents for "a new process of producing and dividing the electric light and apparatus therefor." There were also other inventors at about this time who produced "improved induction coils on secondary generators," as some of them were called, but all seemed to have the idea that they could be operated with their primary coils connected in series, and that their secondaries could be independently controlled. In 1878 a J. B. Fuller, of New York, suggested a system of using induction coils or transformers in parallel, but no practical results seemed to have been obtained in this direction until 1882, when Messrs. Goulard and Gibbs exhibited two induction coils at the Electrical Exhibition held in Westminster Aquarium in London, which ran in operation from the Siemens alternator. In the autumn of 1884, Messrs. Goulard and Gibbs gave another exhibition at Turin. In this case, the primary circuit was nearly 50 miles in length. A series of transformers were placed on this line, one being in the Exhibition building, one at the Turin Railway Station at Verine Riesla; another at Lanzo, a small village in the Alps of Savoy; incandescent and arc lamps were supplied at the various places. The first parallel system that was started on this continent was by Wm. Stanley, jr., in 1884, in the small town of Great Barrington, Mass., where light was supplied throughout the town by means of a parallel alternating current transformer system. From about this time commenced the era of alternating currents, although as far back as 1849 alternating current generators were devised. Commencing with 1885 the alternating current system made great strides.

To employ waterfalls as sources of cheap power, high potentials became necessary. For these conditions the A. C. was especially effective; the ability to step up from low potentials to high, and thus transmit power to a given distance, then to step down to safe and convenient voltages, entirely effectively, convenient and without the use of cumbrous and expensive apparatus, rendered the transportation of the energy of water powers feasible and commercial. Probably one of the first high voltage transmission experiments on this continent was in December, 1891, and in January and February, 1892, at Pittsfield, Mass., at which test the writer had the pleasure of participating. The potential used was approximately 15,000 volts. A transmission line about a mile in length was built in an open lot a little way out of town, where a small experimental station was built. The current was received from the local Electric Light Company at 1,000 volts, raised to about 16,000, sent out on the line, and thence returned, again lowered, first to 1,000 volts, and then again to 100 volts, at which voltage energy was consumed in water rheostats. On the line experiments were made with porcelain insulators, as well as the oil type of insulators. At this time, of course, comparatively little was known about electric current at this potential, so that everything had to be handled with gloves, as it were. The experiment proved to be not only useful and satisfactory, but highly successful, and gave considerable encouragement. Although experiments were commenced, and discoveries made pointing to the advancement of A. C. motors in 1879, still practical results of any real value were not obtained until in the year 1890 to 1891, when the poly-phase systems were introduced. From that time it can be truly said that water powers could be utilized for the general distribution of power at distant localities. One of the first and most notable exhibitions of this kind was made at the celebrated Frankfort Exposition in 1891, which proved not only interesting to the town of Frankfort,

but to the world at large, for it taught lessons and set aside errors that would have taken years of toil and hard labor to have done otherwise. Poly-phase generators having a total capacity of 300 h.p. were installed at Lauffen and operated by water power. From these, the current was transmitted a distance of 110 miles to Frankfort; several voltages were tried on the transmission line during the experiment, the highest of which was 31,000 volts; in the exhibition grounds were arc and incandescent lamps and small alternating current motors, all provided with current from the hitherto "wasted energy" of the streams of Lauffen, and with a loss of efficiency in the line of not more than 25 per cent., which, at that time, was certainly a most noteworthy accomplishment.

During the next two or three years manufacturers spent a great deal of time and energy in perfecting their systems. The induction motor has been perfected to that of an ideal, and the usefulness and necessity of synchronous motors have been established. For a few years following 1891, an occasional poly-phase plant was put up in different parts of the world. They were subjected to all sorts and kinds of trials, depending upon the character of the work to be performed at each individual installation, and although there was often much cold water thrown upon them at the start, and obstacles placed in their way, still they always came out ahead and proved a success, not only from the engineering point of view, but to the financial backers. When we stop to consider that it has been only within the past six or seven years that a complete system has been devised for the utilization of distant water powers, and that all of the important transmission plants have been put in during that time, it is no wonder that there are yet some sceptics. But perhaps worse for healthful commercial developments are those who make a wild rush for some transmission scheme, without first considering all of its surrounding conditions, thinking that because someone else has made a certain project successful, their project must be also. It falls upon the engineer to bring the sceptic to lines of true reasoning and to teach him facts in their true light, so that he will see and believe, that with such resources at his command, great things are possible; the engineer must also hold the enthusiast in check and prevent waste of money in impracticable undertakings.

The primary or fundamental question is to ascertain the point at which transmission of water powers will be a source of profit to the investor. Many people think that because water strictly follows certain given laws of nature, and in doing so continually and constantly exerts energy, therefore the energy obtained thereby costs nothing. People with such ideas are fortunately gradually growing less as time progresses, although the engineer often encounters men who have a few hundred h.p., or oftentimes when the true facts present themselves, only 25 or 50 h.p., that they wish to transmit five or even ten miles, in hopes of making vast sums of money by the use of this transmitted power in some small town for lighting and power. The cost of electrically transmitted power is represented by the interest on the capital invested; the depreciation; the maintenance; the operating expenses and numerous other small contingencies, and besides, in some cases, the amount of money that has to be expended for water and land privileges. The sum of these accounts per year, divided by the amount of h.p. actually sold, will be the actual cost per h.p. for the case in question. Probably the greatest competitor to electric power is steam power. In a few instances, power derived from gas or petroleum engines may also compete. The cost of producing steam power in any given locality is a fair criterion by which to determine how much electric power should cost. The cost of power produced from other sources can usually be disregarded. The cost at which steam power can be produced in a given locality being ascertained, it can be determined what cost per h.p. may be expended on the construction of an electrical transmission plant to make it profitable to the investor, provided again a sufficient market can be obtained for power. When electrically transmitted power does not cost more than $100 to $140 per h.p. installed, the investment is apt to be a profitable one, providing, of course, it is properly managed.

But what should it cost to harness and utilize water-powers? This is a question that has to be figured out for each individual case, for there are hardly two plants where exactly the same conditions exist. The first item of expense is amount required for water privileges. In some cases this is rather an unimportant consideration, while in others it is the chief expenditure, for it may involve the buying of thousands of acres of land surrounding the stream, because the necessary dams may cause to be submerged a great deal of valuable land, or large tracts have to be bought for building storage reservoirs, or the right of way for pipe lines, etc., have to be secured. When land is cheap, these considerations are often not objectionable, but where good farming land, or land valuable for other reasons, has to be thrown to waste, the question is often a perplexing one. The cost of the dam, power house and hydraulic machinery is, as a rule, dependent almost entirely on the characteristics of the stream being utilized. Entering into the question is the amount of water in the stream, both under normal as well as abnormal conditions at various seasons of the year; also the head or fall and whether it is dependent on natural conditions or requires the building of large dams. Generally speaking, other things remaining equal, generating plants, comprising the power house, hydraulic and electric machinery, as a whole cost less as the head increases, until certain limits have been reached. When the head is low, as ranging from 4 to 10 feet, it requires a comparatively large wheel for a relatively small amount of power, and then slow speeds can only be attained. Where large units are desirable, a number of these wheels must be coupled together in order to get the required power. The speed attainable can be raised or lowered to a certain extent, depending on the size of the wheel. If higher speeds at low heads be desired for large units, many wheels must be operated together, requiring not only a great deal of room, and consequently larger power house, but considerable line shafting, gears, couplings, etc., which not only increase the initial cost, but increase expenditure of operation and maintenance of the plant, as well as introducing another source of inefficiency. With higher heads a larger amount of power can be obtained from fewer and smaller wheels with higher speeds, and, therefore, cheaper generating apparatus.

The cost of generating apparatus for a given capacity, other things remaining equal, is almost directly proportional to the speed at which it runs, and for this reason it is always desirable to refrain from too low speeds wherever possible. There are many people who are imbued with the idea that it is impossible to build a modern station without direct connecting all of their apparatus, and that belting at no time should be used. Although direct connection is desirable, still it must not be carried to extremes. A good engineer will hardly warrant the expenditure of, say, $15,000 for a 300 k.w. generator to run at a speed of say 75 to 100 r.p.m., when a machine just as good in every respect, and sometimes better (because it is a standard size), can be bought in belted units for $5,000. Yet this is sometimes done, burdening the plant with many thousands of dollars on which it has to pay money, for no other reason than that "so-and-so's plant is direct connected and I want a plant just as nice and good as his, and belts are always an awful nuisance." As stated before, direct connected units are always desirable where conditions will warrant them, still it must be borne in mind that belts have been in successful operation now for a good many years, and there are many instances where the maintenance of them has not cost 1 per cent. per annum, and although their use involves a loss of efficiency of somewhere between 2 and 3 per cent., at times of full load, still this loss in a water power plant is not a critical amount, and in fact is almost always inappreciable.

The next item of considerable expense is the transmission line—always rather an uncertain item, on account of its variations in cost for different distances and the conditions of local distribution. The poles, with their appurtenances, exclusive of wire, will cost between $250 to $500 per mile, varying according to circumstances. Rights of way for the placing of poles may often be expensive. The transmission wire must be considered separately. Reference has been made earlier herein to the voltage or size of wire. The voltage at which it is practicable to run now-a-days is reaching vast proportions. There are two or three plants being installed in which 20,000 to 22,500 volts will be used, and a plant is likely to be installed soon that will use 60,000 volts. The use of high voltages in the past has been limited greatly by the insulators. The glass insulator has proven itself insufficient for most climatic conditions. The oil type of insulators was introduced some years ago, and a great deal expected from them. They did give excellent results in the

laboratory, but unfortunately the oil evaporates and the impracticability of renewing the oil, especially when the line is in use, soon put them in disfavor. Porcelain insulators appear to have solved the problem. The trouble at first was to get them properly vitrified, but this difficulty seems now to be overcome, and the insulators have proven all that can be desired when used with the usual voltages now employed. As to whether they will successfully cope with the higher voltages now contemplated is a question yet to be answered. The cost of the transmission wire is often the most important part, but it is always different with each case, dependent, as it is, upon the amount of power to be transmitted, the transmitting voltage, distance, and the allowable loss. As a whole, it is always best to keep the transmitting voltage as low as possible and still keep within commercial conditions. Many people are carried away with the idea that if they could only use high voltages the cost of transmitting would be reduced to a minimum. It must be borne in mind that with the use of the higher voltages the cost of insulators increases, the electrical apparatus necessarily costs more, and moreover, the risks are greater throughout the system, and consequently necessitates more skilled attendants to look after the plant.

All of these items have to be carefully considered before looking into the possible saving of copper on the line. For mechanical reasons, a wire smaller than No. 6 B. & S. should not be used for line work. More cautious engineers will say it should not be smaller than No. 4 B. & S. It is foolish to attempt to use voltages which allow the use of smaller than No. 6 wire. Where a shut-down would mean heavy damages, it might be even advisable to use a wire not smaller than a No. 2 B. & S. If these facts are always borne in mind, the question of voltage will oftentimes adjust itself, and the use of very high voltages will not be found necessary unless the transmission be for especially long distances, and the amount of power particularly large. The permissible drop is dependent upon the power obtainable at the generating station and the amount to be delivered at the end of the line. There are a few instances where power is scarce at both ends of the line, and where it is desirable for this reason to keep the loss of transmission as low as possible, but such cases as a rule are rare, and we are more often met with the reversed conditions. To get good results electrically, the loss in the line should not be more than 15 per cent. If it be more, it will, with the other losses that are necessary in the rest of the apparatus, especially where the load is liable to be a fluctuating one, render good service almost impossible. The figuring of drop on transmission lines should always be left to competent engineers, for with A. C. the question in many instances is not a simple one, because it involves other conditions besides the ohmic drop. When alternating current is sent through a conductor, it has to deal not only with the electric resistance of the wire, but also with a resistance due to the fact that the electric magnetic stresses set up at any point of the conductor, create electromotive forces at other points of the same conductor, which oppose and retard the passage of the current, or in some cases, tend to shove it ahead. As to how far power can be transmitted, the engineer can conscientiously say to an indefinite distance, and he would be fully prepared to figure out, and contract for, if necessary, the fulfilment of his statement, but it rests with the commercial men to cry halt. The distances attainable, however, on a profitable basis, have been growing greater from year to year, as the manufacturers have been prepared to extend the limit to which they are willing to build high tension apparatus. At present it would appear that where the distance to be transmitted is over 75 to 100 miles, no matter how cheap the hydraulic development, commercial competition is not practicable with existing power where coal can be obtained for $2, $3 or even $4 per ton.

The step-down station and the distribution of power are the next items of expense, including the cost of the necessary switchboards, transformers, etc. The location of the step-down station and the method of the distribution of power constitute a very important question. Unfortunately, very often this subject is entirely omitted or overlooked by the promoter, but it is one to which should be given considerable thought. The step-down station itself should be centrally located, so as to make the distributing lines as short as possible. It is not generally advisable that transmission lines of very high voltages and large currents be extended through thickly settled communities where they might be liable to disturbance from fire or accidents of similar character, in the immediate locality of the line. In some places, to enable the distribution station to be centrally located, transmission wires are placed in conduits underground, when they pass through thickly settled districts so as to avoid the danger that would otherwise exist, but this, of course, is expensive construction, and the cost of it must always be balanced against the advantages of having the step-down station centrally located, as against its being placed at the outskirts of the town. All the various items require careful study to obtain least cost and avoid unwise economies.

When all these various factors have been properly adjusted and the resulting condition of the water power electric plant is that the power available twenty-four hours every day is at or about the cost of steam power in any given locality, the future profitable operation will be, no doubt, assured, because the popularity of electric power is not due alone to the fact that it can be produced cheaper than power obtained from other sources, but also to its superiority in other directions. This is evidenced by the fact that in mills and factories, where both sources of power have been tried, electric power is displacing the steam plant. Owners having experience with both invariably state that they would not be willing to return to their former power plants, even if power could be produced as cheap or cheaper than they are now obtaining it for electrically. The reasons for this are very numerous. The power is always on tap day and night, year in and year out; there is no waiting for boilers to be fired, nor shut-downs on account of strikes at some distant coal field; less room is required, and consequently floor space formerly occupied by belts and shafting can now be easily sub-divided into any number or sizes of units, and thus independent departments and machinery can be worked separately instead of from one big unit. Overtime work in any department is much cheaper, for by having departments separately operated they can be run independently at will, without running all the other machinery in the mill. The fire risks are less, and rates of insurance less for mills operated electrically than by other means. Removal of so many belts, line shafts, pulleys, etc., secures less danger to life of mill employees, and the mill is lighter and cleaner, and consequently the health of operatives better. On account of the extreme simplicity of the A. C. electric apparatus, anybody with ordinary intelligence can start it in motion, and thus avoid depending on one or two men. Moreover, with electric power it is possible to maintain a closer speed, which in many instances enables the turning out of a larger quantity of better product commanding higher price; and so on for most every department and branch of business, some advantage is gained without anything lost. All of these advantages are not evident to the consumer before or when he first puts in electric power, and he often refuses to listen to them, thinking that they are entirely imaginary, but a short experience brings the conclusion that electric power is "cheap at any price." It may be interesting to note here that there is a project now on foot in which it is contemplated to transmit 30,000 h.p. a distance of between 30 to 40 miles; the transmitted power to be used in mills now operated through shafts, gears and belting by water wheels, because of the advantages to be gained by using electric power.

The use of electric power is not confined to driving machinery in mills or factories, for it is fast finding its usefulness in other directions. The use for "electro chemical" enterprises is fast reaching vast proportions, and there are plans now on foot for the utilization of at least 150,000 h.p. in this way during the next two or three years. There are many thousands of h.p. being used in the street railways, while the big trunk lines are seriously considering its use, and are continually asking the manufacturing companies for plans and estimates. Then there is the electric welding, the electric plating, the supplying of energy to horseless carriages and electric launches, to say nothing of the hundreds of thousands of incandescent and arc lamps that are used for general lighting. The utilization of the water power by electric transmission has not stopped with the commercial world, but has forced itself into the privacy of our own homes, not merely with incandescent lamps, but with electric cooking utensils, smoothing irons, electric heaters, fan motors, etc. What would our forefathers say if they were told that to-day we are depending on such and such a river, so many miles distant, to cook our meals for us and to have our boiled shirts laundered; but we had better not laugh now, for the coming generations may have as much occasion to laugh at us.

This paper was so admirably read that A. A. Wright jocularly asked whether the position of permanent reader to the association was open. If so Mr. Browne should be asked to take it. Wm. Thompson, Montreal, regretted very much that Mr. Magie's paper, which covered the whole ground before him, had not reached the hands of the members before the day of reading. He (the speaker) was only about 30 years old, but he could remember his grandfather running a mill in England by one of those lovely water wheels on which the water dropped from a great height above. Some friend came along and said, why don't you put buckets on your wheel and catch the water, thus suggesting an improvement which waited years for adoption. Mr. Magie properly pointed out that water motors for electrical transmission had come to stay, and was wise in pointing out to the investor that there are occasions when an electrical installation cannot pay. It is a pity that the installations near Montreal are not more advanced so that the investor could see what returns are likely to be made. The Lachine plant, for instance, represents a large capital that will be locked up there for years to come. In conclusion he felt like proposing that the discussion of this paper be postponed till next year, so that members might have a fitting opportunity of studying it. W T. Bonner, Montreal, thought that the steam men had been slightly disparaged. He expected that during the coming six months some tests would be made of important existing plants which would educe surprising results in favor of steam. He hoped to submit them at the first opportunity. W. H. Browne, Montreal, objected to the postponement of the discussion as it might bring on new phases of the subject and there were several members present who were capable of discussing the paper. He was perfectly aware that steam plants showed up very well in comparison with electricity, and indeed the paper pointed out that the initial cost in many cases rendered the installation of electricity prohibitive as an opponent of steam. But the use of the steam plant at unaccustomed hours involves extra cost while that of electricity does not. The largest commercial enterprise in Montreal has negotiated for electric power and has altered the working hours so as to recoup itself. A. A. Wright, Renfrew, thought the subject, in this age, of the utmost importance. Small towns in particular would be much benefited if the water powers in their vicinities could be used. A. M. Wickens, Toronto, also regretted that the paper had not been handed in earlier. Much could be said in favor of the steam end of an electric plant. You see, he said, this association reaches from one end of Canada to the other and includes many districts where there is no water power, and in such places the steam engineer will crowd his electrical rival very closely. Even where there is water power the results are not absolutely convincing. Take, for instance, the Cataract Construction Company on the American side of the Niagara Falls. No one knows whether they are making anything or not, or what the cost of transmission is. We know that a vast sum of money is sunk there, and that so far very little power is transmitted to Buffalo. About everything else we are left in doubt. J. J. Wright, Toronto, endorsed much of what had been said, but fancied that the steam engineers were not quite so sure of their facts as the electrical. L. De W. Magie said that if it had been his intention to fight the steam men he should have written a different paper. W. Thompson, Montreal, said that Mr. Magie had made his statements mildly, and agreed with much the writer said. The trouble is we put in 20,000, 30,000, or 40,000 h.p. plants and we are able to find customers only for about one-tenth. Too many people imagine that because the waterfall turns the wheel that therefore power ought to be free. Where large installations have been attempted too much money has been sunk to obtain power vastly in excess of the demand. Montreal is of course exceptional because of its promise and opportunities. Still it is not exempt from the charge. B. H. Reesor, Lindsay, moved a hearty vote of thanks to Mr. Magie.

W. T. Bonner, Montreal, then read his paper on "The Unconscious Ownership of an Important Key."

THE UNCONSCIOUS OWNERSHIP OF AN IMPORTANT KEY.

BY W. T. BONNER, MONTREAL.

The first consideration in exploiting any new suburban tramway is the possible or available passenger traffic. That being found inadequate to guarantee a fair return on the cost of installation and maintenance, the project is usually abandoned for the reason that only passenger traffic can be considered, owing to the high cost of handling goods traffic at the terminals. While a motorman and conductor are sufficient to handle a two or three-car electric train for passenger traffic, with very little expenditure of time or assistance for loading and unloading, all railways under present systems require a large additional force to conduct the hundreds of details attending the reception, checking, loading, transferring, unloading and proper delivery, in good order, of either car lot or package freight. It may therefore be conceded that the whole subject presents two phases of commercial economy, viz.:

(a) From the standpoint of the agriculturalist and land owner; how best to provide a means for increasing the value of remote lands.

(b) From the standpoint of the capitalist; how best to increase the earning capacity of suburban lines.

With the ever increasing centralization of population and commerce, inaccessible property becomes less valuable; all land, whether barren or fertile, suffering alike, according to its distance from the centre of demand for farm products, which we call markets. Such distance is not always measured in actual miles, but rather in accessibility, since in our day we find frequent examples of the long and short haul rates. The Minnesota and Manitoba farmers will deliver their wheat at the seaboard at a lower cost per bushel than the farmer who may live a hundred miles off the coast. The eastern farmer may have just as fertile land as his western competitor, but he is handicapped by having to haul his wheat forty or fifty miles over poor wagon roads to reach the nearest railroad. In either case, the terminal charges, including the cost of loading the produce at the farm, is approximately the same, but the difference in cost of haulage per ton-mile by railroad and wagon road is in favor of the former. It has been stated as a fact that to transport a ton of coal from Buffalo to Chicago costs no more than to move the same quantity of coal across the sidewalk in either city. It is frequently asserted that since the introduction and development of steam railways, they have gradually superseded the earlier methods of transportation and traffic, and as a consequence highways are no longer an indication of progress. This is true only to a limited extent. Railroads have changed the character of suburban traffic, and personal travel is no longer dependent upon the condition of the highways, but commercial intercourse, as represented in the exchange of products, is as much dependent upon the condition of the public road to-day as it ever was, for the reason that it is impossible to construct a railroad to the door of each producer and consumer.

Few people have any knowledge of the real cost of transportation by horse and wagon. The following table shows the cost of moving a load of one ton a distance of one mile on level roadways, with different pavements and under average conditions:

	Per ton-mile
Iron Rails	$ 1.28
Asphalt	2.70
Stone, paving, dry and in good order	5.33
Stone, paving, ordinary condition	12.00
Stone, paving, covered with mud	21.30
Broken stone, dry and in good order	8.00
Broken stone, moist and in good order	10.30
Broken stone, ordinary condition	11.90
Broken stone, covered with mud	14.30
Broken stone, ruts and mud	26.00
Earth, dry and hard	18.00
Earth, ruts and mud	39.00
Gravel, loose	51.60
Gravel, compacted	12.80
Plank, good condition	8.80
Sand, wet	32.60
Sand, dry	64.00

From the foregoing table, and from statistics gathered by both state and national bureaus, it has been calculated that the average cost of transportation by animal power is twenty-five cents per ton per mile. Furthermore, the rate of transportation by animal power is, and always has been, excessively high, and the evidence of statistics shows but slight improvement as compared with the progress made in other departments of industry, and by other means of transportation.

One fact is patent to all, that whereas formerly the distribution of population was approximately equal over the face of

the country, it is gradually becoming concentrated into large cities to such an extent that already fully one-half of the inhabitants of the older sections of the country live in cities. The evident reason for this is competition, the demand for increased output at reduced cost. Concentration indicates increased power for production. Take, for instance, some of our commonest staples, like wheat, beef, pork, molasses, wagons, horseshoes, butter and clothing. Within the writer's memory, these articles were produced at homes, or in small shops and factories distributed, like the population, quite equally throughout the country at cross roads and villages, utilizing crude methods and operated by the old-fashioned treadmill or horse power, and overshot water wheels. The output of flour per man per day in those mills did not exceed ten barrels. At the great Winnipeg and Keewatin mills, and at Minneapolis, the milling business has been so concentrated that to-day the output per man exceeds 100 barrels and the cost of production is correspondingly reduced. But of what benefit to inaccessible property in the interior is this reduced cost of production, unless like facilities for transportation are afforded ?

The measure of benefit which any improvement in production in one community bears to another community, depends entirely upon the transportation facilities between the two places.

Concentration of population and production requires for the better equalization of supply, and price of materials and provisions, that such centres must be provided with commercial veins and arteries which shall quickly and cheaply transport or exchange urban and suburban passengers and commodities. While long haul rates of transportation by railroads and steamships have been wonderfully cheapened, there still remains a space of fifteen to twenty-five or even forty or fifty miles surrounding every commercial centre, which has never been covered by any cheap method of transportation. Such distances are beyond the possibility of cheap or efficient service by animal power, and the terminal charges and bulky plant required, precludes any possibility of much reduction in railroad tariffs. What we require therefore is a new system of transportation which shall be alike available for freight and passengers. The problem of handling exclusively passenger traffic is comparatively simple; indeed it has already been solved for those districts where the population is sufficiently dense to support steam or electric tramways requiring no other source of revenue. Experienced railroad men are unanimous, however, in agreeing that no road, whether steam or electric, will pay in a thinly settled district, unless assisted by a bonus or by the addition of freight traffic.

The latest development in the line of providing for goods traffic on electric tramways came to the writer's notice some months ago in the shape of a combination vehicle, so constructed as to be readily convertible for use upon any ordinary roadway or upon a railroad track. It can be shifted from one to the other without the necessity of reloading or rehandling the contents between points of shipment and destination. The wagon proper is patterned after the ordinary improved road wagon, modified, of course, for the special nature of the service contemplated. The running gears and springs are of standard construction, having a carrying capacity of from three to seven tons, depending upon the class of freight to be carried.

The rail truck is not materially different from the car truck in general use upon our electric railways, except that it is provided with special attachments for automatically gripping and supporting the wagon proper. It has cast steel segments or dogs, supported in place horizontally by heavy plate springs, and used for the purpose of engaging the axles of the road wagon as the truck approaches from either direction. As the truck is drawn forward on the level rail by the electric motor, the impact of the projecting dogs against the wagon axles also starts the wagon forward, and as the latter travels down the inclined switch track, the axles gradually settle into the notch provided in the cast iron journal frames.

The actual time required for unshipping the wagon from the truck for road use, and vice versa, is not more than would be required for coupling together cars in making up a train. The weight of the combined wagon and truck is sufficient to insure perfect rail traction and the proportion between carrying capacity and dead weight averages about the same as the ordinary freight car. By establishing a uniformity of dimensions and making the rail truck interchangeable, the wagons can be loaded either end on from either direction, and any number of rail wagons can be connected and moved in either direction as a train, by steam, electric or other motive power.

W. H. Browne said Mr. Bonner had submitted a conundrum. He took it as a suggestion that the railroads should lend their lines for the transmission of parcels free, and thus make unnecessary the aggregation of population in large cities. G. H. Hill, Montreal, said that while the scheme was, no doubt, an interesting one, it was open to question. It proposed to do away with the frequent handling of products and seemed beautiful up to the point where the car is sidetracked. But it means the lying idle of a certain amount of rolling stock, and it is a question whether the producer could not bring his stock down to a certain point where it could be taken up by the train. Then he loses the ownership of the material the moment it leaves his yard. Now the railway company is not going to do the work of a commission agent for nothing. The speaker had run over a number of suburban routes, noticeably that of Grimsby, where the system seems to give first-class results. They run through a most fertile country tenanted by large fruit growers and farmers, who all need a certain amount of power at all times—threshing, pumping, churning, and yet strange to say the suburban company will not even think of taking power from their circuits. In Manitoba and the North-West Territories he knew of a scheme which was being evolved by some engineers who figured out that the farmer of Manitoba, with the straw annually burnt up, could do all the work of his farm by electric power. The discussion was continued by A. A. Wright, J. J. Wright, L. De W. Magie, C. H. Wright and W. H. Browne. G. H. Hill moved and E. D. Ellis (Barrie), seconded a vote of thanks to Mr. Bonner. The president in tendering the vote remarked that before you could get the farmers to use power you must have some model establishment showing what can be done.

A telegram from John Murphy, on behalf of the Ottawa Electrical Association, was read, wishing the association a profitable and pleasant convention in the commercial metropolis of Canada.

In the evening, on invitation of the Montreal Park and Island Railway, the members enjoyed a trip around Mount Royal, where a good view of some of Montreal's handsome suburbs was obtained.

Wednesday, June 29th.

The first business of the day was the presentation of the Secretary's report, from which it appeared that there had been five committee meetings during the year ending 31st May last. At the first a Committee on Mileage and Transportation was appointed. At a later meeting committees on general arrangements and on papers, and the secretary was instructed to render accounts to members in arrear for fees and make drafts if amounts were not paid within reasonable time. At the meeting of May 25 nine persons were elected to membership and the resignation of ten members accepted. In the early part of this year a pamphlet setting forth the character and purposes of the association was prepared and printed under the direction of the Executive. About 800 copies of this have been judiciously distributed. Particulars of other important work are to be found in the report of the Committee on Legislation. Incidental reference was made to the recent formation of the Maritime Electrical Association, of which F. A. Bowman, of New Glasgow Electric Company, a member of the Executive of the Canadian Association, is the president, to promote electrical interests in the Province of Nova Scotia and New Brunswick. During last year death entered the ranks of the association and caused the loss of Charles Ernst, of Detroit, and Ross McKenzie, of Toronto. During the year there were dropped from the roll the names of 21 members, 12 active and 3 associate members having resigned; 2 having died and 4 having changed their place of residence without furnishing their new addresses. Since the 1st inst. 2 additional resignations have been received and the names of 13 members struck off the roll for non-payment of fees. Thus there have been removed from the membership list since last convention 36 names. During the same period there were added 68 active and 11 associate members—a total of 79, leaving the present total membership at 234. The Financial Report for June, 1897 to May, 1898 shows total receipts $790.82 including a balance at the bank of $410.57. Bringing the financial operations up to June 29, the total at credit of the asociation is $588.75. The report was adopted, and the secretary thanked for the care with which he had prepared it.

REPORT OF COMMITTEE ON LEGISLATION.

Your Committee beg leave to report that in pursuance of the motion passed at the last convention held at Niagara Falls, instructing your Committee to take up the matter of securing legislation in connection with the movement among municipalities in Ontario to enter upon electric light undertakings, in unfair competition with companies already in existence, your Committee held their first meeting at the close of the convention. At that meeting it was decided to procure an opinion from Donald Guthrie, Q.C., ex-M.P.P., of Guelph, and to retain him professionally on behalf of the Electrical Association in connection with the question. Various questions were submitted to Mr. Guthrie, and his opinion in answer to these questions was considered at a meeting of your Committee held in Toronto on the 9th of November.

A bill was prepared which came before the Municipal Committee of the Legislative Assembly on the 12th of January. Your Committee in preparation for the meeting, assembled in Toronto on the 11th, and also on the 12th, and attended the meeting of the Municipal Committee for the purpose of supporting the bill. The Committee had also the assistance of Z. Lash, Q.C., with Mr. Guthrie.

After discussion, those representing us consented to a suggestion of the Honorable A. S. Hardy, Chairman of the Municipal Committee, and other members of that Committee, to allow the matter to stand over for another year. The discussion, however, brought out the fact that there was really no sound answer to the principle of the proposed measure. It also evoked an expression of opinion from the leading men of both political parties to the effect that the underlying principle of the bill was just. The Municipal Committee thought that there was not proper time to consider how the bill would affect places where there were more than one existing plant, also places that derived or may derive power from points outside the municipality, also to consider the length of the life of an electric plant and other questions, and in the judgment of the Municipal Committee any bill dealing with the matter would require more ample public discussion and some modification. The action of your Committee and the discussion the question has received, has tended to bring into prominence the injustice of the present law. The necessity and propriety of some measure of relief may be considered now to be more generally admitted. The work thus inaugurated and which has attained a hopeful position, should not be discontinued. The present law of Ontario is inequitable towards lighting and power companies, because it permits a municipality, after it has given its sanction to the formation of such a company and has encouraged enterprising citizens to embark their capital in it for the purpose of supplying the municipality wtih light and power, to turn around and destroy, with public funds, and without public necessity or advantage, the value of the property of those citizens who were encouraged to invest their private means in the enterprise. What evidently struck the majority of the members of the Municipal Committee was that the proposed legislation was just and equitable because, while it did not prevent municipalities entering upon municipal supply of lighting if they so desired, it made provision for extending the existing law regarding water works to the case of lighting companies. This law is to the effect that where a municipality desires to supply water and there is an existing water company incorporated for the municipality, the council shall not levy any water rate until the council has, by by-law, fixed a price to offer for the works or stock of the company, nor until after thirty days have elapsed after notice of such price has been communicated to the company, without the company having accepted the same or having, under the provisions of the Municipal Act as to arbitrations, named and given notice of an arbitrator to determine the price, nor until the price accepted or awarded has been paid or has been secured to the satisfaction of the company; the price to be determined by arbitration under the provisions of the Municipal Act. It will be observed that this provision in no way interferes with municipalities going into the supply of water. It simply provides that if they do enter upon such undertaking they are by this law bound first to try to buy at a fair price, or at a price to be fixed by arbitration, existing waterworks. No good reason can be advanced why this law should not be extended to lighting and power companies as well as to waterworks. It is eminently just, and it imposes no hardships on the municipalities; nay, rather, it benefits them, because it tends to extinguish rivalry to themselves, which rivalry might render municipal operation of these works unprofitable, and at all events it puts them in possession, at a fair valuation, of the very plant and material that they would have to purchase from other people if they are going into the business. The proposed legislation is in the public interest, because it will further encourage private citizens to invest their capital in extending and improving existing lighting and power works. It was generally acknowledged by the Municipal Committee that electric light companies as well as water companies have always come into existence with the consent, encouragement and approval of the municipality, which has granted the use of the streets, etc., for these works.

It ought to be mentioned that all the members of your committee paid their own traveling and other expenses in connection with attending the meetings. The movement amongst municipal corporations to enter into the lighting and power business in competition with those who had the courage to be pioneers is growing, and unless regulated in some way by the legislature, will result in the confiscation of a large amount of capital invested in the business, as witness the town of Barrie now preparing to put in a complete plant, including arc, incandescent and power services, to be paid for out of public funds, for the purpose of competing with and destroying the Barrie Company, a private and lawful enterprise.

In the course of the discussion S. Noxon, Ingersoll, expressed his sympathy with the work of the committee and said he believed there was an Act in Scotland providing against municipal confiscation. British law has wisely been taken as a precedent, and it might be so taken now. An electric light plant needed protection in this respect more than a waterworks plant, for the latter was of a permanent kind, while an electric light plant was subject to frequent change from the constant improvement going on, and a plant that is considered efficient now might soon become obsolete. In certain circumstances this might be an argument against us, but in other cases, as for instance, that at Barrie, where the municipality refused to treat at all, the cancellation of existing rights would be a double injustice to private ownership. E. D. Ellis, Barrie, referring to the case of his company, said they had been for two years without a contract with the town. The town authorities would not talk to them at all. His company wrote that they were anxious to be on a proper footing and would even sell out their plant at its proper value. The town told them to put in a tender along with other tenders they were calling for, which was not fair to the company, who protested that this was not fair, and offered to leave it to three competent men as arbitrators. The town would not arbitrate. Other towns were evidently watching the result of this case.

The president said he had followed this subject closely for some years and his experience had been that most people are anxious to reap where others have sown. The first bill provided against this in a way, but the committee were impressed with the conviction that these difficulties have to be openly discussed and fairly met. The committee did not feel inclined to go on with the bill that session but were urged on from various quarters, and a short bill was prepared with the idea of a larger measure in the future. The Hon. Mr. Hardy said he had no doubt that municipalities in the future would submit to arbitration. J. J. Wright, Toronto, said the strongest emphasis should be laid upon the point of arbitration. When a plant is purchased by arbitration it should be at its value, and it is worth as much to the municipality as to the private corporation. The separation of the public lighting from the private and commercial branches would mean ruin in many cases. He could not understand why the electric light industry should be singled out for so many attacks. There seems to be an exasperating glamor about electricity, probably owing to the superstition that there is lots of money in it. The chairman said people in small towns have a notion that a dynamo set up beside a water wheel will produce power for nothing. Mr. Wright—That is what they think in Toronto. Mr. Noxon thought the supply men were frequently to blame for encouraging municipalities in this course. Mr. Wright thought more harm was done by "half baked" dynamo tenders who pose as electricians than by the supply men. B. F. Reesor, Lindsay, said the Municipal Act of Ontario clearly stated that where a bonus is given to a town it shall not interfere with any existing interests, and he believed that taking this as a principle of law, if a test case were made where a municipality attempted to crowd out

a private company without arbitration, the highest courts would affirm the company's rights, even without a special act. The chairman said lighting companies do not get bonuses and free sites like many other industries, and that is one of the hardships of the situation. A. A. Wright, Renfrew, said it was a difficult subject. There were political enemies as well as electrical enemies. An eye should be kept on the electrical supply men, who by telling half the truth to municipal authorities do incalculable harm.

This led to a tilt between the electric supply men and other speakers in which the former said they were "out for business" just the same as the electric lighting men, and it sometimes naturally happens that they cross each others paths.

The following standing committees were then appointed:

Statistics.—J. A. Kammerer, Toronto; A. A. Wright, Renfrew; S. J. Parker, Owen Sound.

Meter Inspection.—A. A. Dion, Ottawa; E. E. Cary, St. Catharines; J. J. Wright, Toronto.

Legislation Committee.—John Yule, Guelph; C. B. Hunt, London; B. F. Reesor, Lindsay; J. J. Wright, Toronto; W. H. Comstock, Brockville; F. Pepler, Barrie; A. L. Breithaupt, Berlin; C. Berkeley Powell, Ottawa.

NEXT PLACE OF MEETING—HAMILTON.

A letter was read from the Cataract Power Company, of Hamilton, extending an invitation to the association to hold its next meeting there. This was heartily endorsed by several members from Hamilton, and on putting it to the meeting the invitation was unanimously accepted.

J. J. Wright proposed, seconded by B. F. Reesor, that the remuneration of the secretary be $125 per year.—Carried.

Geo. H. Hill, Montreal, drew attention to the need of proper inspection of electrical construction, and thought that the Fire Underwriters should provide a competent inspector. At present there was no uniformity in inspecting, and in Montreal electrical men never knew where they were. During the discussion Mr. Browne, of the Royal Electric Co., said his company had already solicited the Government to appoint a competent inspector, but so far without success, and the company had to formulate rules of its own, which were generally accepted. Ald. G. W. Sadler said the City Council were now codifying general rules for building, plumbing, etc., and he would be happy to co-operate with a committee of this association with a view to having a set of rules for electric wiring and fixtures incorporated in these new rules.

On motion of Mr. Wright, Toronto, a committee consisting of A. A. Dion, Ottawa; F. H. Badger, jr., Quebec; P. G. Gossler, Montreal, and Ald. G. W. Sadler, Montreal, was appointed to meet the Boards of Fire Underwriters, and deal with the question.

Dr. J. K. Johnstone, Inspector of Electric Lights, Toronto, then read a paper, entitled "Experiences of an Inspector," which was well received.

EXPERIENCES OF AN INSPECTOR.

BY J. K. JOHNSTONE, INSPECTOR OF ELECTRIC LIGHTS, TORONTO.

When honored by an invitation from the Executive to prepare a paper for the society, I was somewhat in doubt as to the choice of a subject. I wished to furnish something that might be of interest to you and at the same time to avoid any of the important branches of electrical science which might leave me liable to criticism from gentlemen so highly qualified; hence, with your kind permission, I will confine myself to giving you a few impressions as received in my capacity as inspector.

At the introduction of the government inspection of electric lighting, there were a few, as you may remember, opposed to the act, and I acknowledge that it was with some misgivings that I went forth on my duties. However, it is with pleasure that I can now recall every visit made to the electric light stations in my district, and in every instance have I not only been kindly received, but every suggestion of improvement offered by me has been acted upon immediately and with evident pleasure. I need not tell you that in not one instance have I found any attempt on the part of electric light companies to defraud their customers, although occasionally appealed to by consumers on that ground. An investigation usually resulted in discovering old lamps, too few lights for the space lit, wastefulness where a meter was in use, or some other fault in the power of the consumer to correct.

The persistence of many purchasers of electric light in clinging to old and useless lamps is a common source of annoyance to the companies and a difficult matter to overcome. The old lamp is often expected to give as brilliant a light as when first installed, and when unable to do so the charge is frequently made that the company supply a too low voltage. To please these grumblers, a mistake is sometimes made in endeavoring to supply a current sufficient to brighten these worn-out lamps, and this, too, at the expense of new lamps, whose brilliancy is thus deteriorated. As it is impossible to compel the purchase of new lamps, and as the companies are anxious to please their customers, I have suggested, when consulted, that new lamps should be supplied at their actual cost, thus throwing the blame on the consumers when their lights were poor, economising electric current and sparing new lamps.

The question as to the advisability of using meters, where practicable, can only be answered in their favor. By the employment of a meter a just system is accorded to manufacturer and consumer alike; the wasteful man is made to pay fairly for his neglect, while the careful and honest man is charged only for the light needed and current consumed. Under the flat rate system, it is not uncommon to see large shops brilliantly illuminated throughout the entire night. Managers tell me that it is difficult to introduce the meter where flat rates have been charged, but, despite the objections, many are making the change. The several types of dial registering meters which I have inspected are usually accurate, and I am told prove satisfactory as measuring instruments for either power or light.

A lack of uniformity in rates, both by meter and flat rate systems, has been a subject of complaint with some managers. There is evidently no remedy for this unless an arrangement can be arrived at by the manufacturers themselves and a standard charge agreed to.

In several towns in the district visited by me, a system of street lighting by incandescent lamps has been adopted. When properly arranged the appearance is quite pretty and the light well distributed.

In concluding, permit me to tell you that the managers and electricians I have met in my work are, without exception, kindly and intelligent men, and in this favorable opinion I am borne out by other inspectors with whom I have spoken upon the subject. It has been suggested to me that there may be some potent and subtle charm in the electric current which develops the best qualities in a man's character. Can this be so?

W. T. Bonner, Montreal, read his paper on the "Quimby Screw Pump," which has been crowded out of this issue.

Mr. Bowman's paper on "Methods of Illumination" was taken as read, and the paper promised by Mr. Hopkins on electricity in Rainy River was not received.

The afternoon was devoted to social features. The first event was the inspection of the Bell Telephone Co.'s new building, where L. B. Macfarlane, the genial general superintendent, had a staff of the company's employees, who took charge of the visitors in groups and explained the wonderful complexities of the great exchange room, one of the largest and most perfect telephone exchanges in the world. After this the Montreal Street Railway Co., which had provided special cars to bring them down here, conveyed the visitors to the company's great power house, where 8,000 horse-power was observed in operation, the new 4,000 h.p. engine—the largest in Canada—being particularly admired. Four big pleasure vans were in waiting for the company at the corner of McCord and Seminary streets, the distribution station of the Lachine Rapids Hydraulic and Land Company, and after inspecting this building the party were driven to the big power house at Lachine Rapids along the picturesque Lower Lachine Road. Dismounting here the visitors were first shown the sea of rapids that tumbled and roared beyond the embankment at the outer end of the power house, and then they were shown the long gallery of turbines, and four large generators in operation. These generators, which were built by the Canadian General Electric Co., have previously been described in The Canadian Engineer in connection with an account of the Lachine Company's works. The inspection over, the visitors were invited to a cold collation and liquid refreshments which were enjoyed very much. Senator Thibaudeau, president of the Royal Electric Co., in a few

graceful words, conveyed the thanks of the association to the company and said of Mr. Walbank, the general manager, that the longer he had known him the more he esteemed his genial qualities, and he trusted he would be rewarded with all the success his enterprise and foresight merited. Mr. Walbank, replying, thanked the honorable senator for the compliment paid him, which he valued the more coming as it did from the head of a rival company. [Senator Thibaudeau.—Say "elder sister."—Laughter.] Mr Walbank took occasion to correct a member who on the previous day, speaking of unremunerative schemes that supplied more power than was demanded, said this company had only two generators running and not paying. As a matter of fact there was only one generator at present running during the day when lights were not in use, but at night there were three dynamos running, and the company was quite satisfied with the prospects. The visit closed with three cheers for Mr. Walbank, and the visitors were driven to the head of the dam, where they arrived just in time to see the steamer Sovereign run the rapids. The party returned to the city by way of the "Glen" and Dorchester street, and were set down at the Windsor thoroughly pleased with the excursion. The refreshments and conveyances were supplied jointly by the Canadian General Electric Co., and the Lachine Rapids Co.

THE BANQUET.

The annual dinner, which took place at the Windsor on Wednesday evening, 29th, will be remembered as the most successful in the history of the association. President Yule made an excellent chairman and kept the business of the evening moving without any tedious hitches. The dinner itself did credit to the Windsor's well-known reputation. The cover of the programme had the association's monogram and maple leaf in gold, and the covers with menu and toast list were held together by covered copper wire. The menu was as follows:

MENU.

Long Distance Transmission.
Fire Island Cocktail—50,000 Volts.
Internal Resistance.
Cucumbers Radishes
Tomatoes, strain Insulators. Olives tripled Braided
Electric Juice.
Green Turtle, a la Water Rheostat,
Cream of Asparagus, a la Ozone.
Submarine.
Saguenay Salmon, a la Hello, Potatoes, Rachel.
Shunts.
Spring Lamb Cotelettes, Sweet Breads,
Carbon Trimmed,
Asparagus—"Arrester" Points.
Joints—"Soldered and Taped." Filets of Beef, Larded
Relays and Sounders, String Beans,
Boiled New Potatoes, Anchors,
Cauliflower, Asparagus, Sweet Peas.
Trolley off. Punch au Champagne.
Reconstruction.
Roast Philadelphia Capon, Plants, Lettuce and Tomato Salad.
Boosters.
Cabinet Pudding "sound proof,"
Gelee aux Oranges, "insulating compound."
Savarin aux Ananas, "vacuum light,"
Vanilla Ice Cream, "self cooler."
Sponge Cakes, "Leather Belting."
Dessert.
Fruits, "potential currents," Nuts and "wrenches."
Electric heater, Incandescence
Cafe Noir, Cigars.
Transfer. Ring off. Open Circuit. "30."

On the chairman's right sat Mayor Prefontaine, Ald. Sadler, Dr. W. H. Drummond, C. B. Powell, and on his left the Hon. Senator Thibaudeau, W. R. McLaughlin, L. B. McFarlane, D. A. Macdonald, W. H. Browne, C. B. Hunt and P. W. St. George. The others present were: J. A. Kammerer, Toronto; John Carroll, Montreal; Samuel Adams Chase, New York; P. G. Gossler, L. D. W. Magie, Wm. T. Bonner, W. E. Quimby, F. W. Fairman, J. C. McCormick, R. H. Bartholomew, Wm. Smyth and John J. York, Montreal; A. A. Wright, Renfrew, Ont.; C. H. Wright, Alex. Barrie, William B. Shaw and D. W. McLaren, Montreal; Andrew Sangster, Sherbrooke; Geo. C. Rough, T. W. Atkinson, H. J. Gardiner, R. Dobie, H. J. Fuller, James A, Baylis, P. H. Hart, Fred. S. Hickey and James H. Campbell, Montreal; A. M. Wickens, Toronto; J. F. H. Wyse, Brantford; V. B Coleman, Port Hope; E. J. Kyle, Kingston; H. A. Moore, Trenton; J. W. Campbell, J. S. M. Ridley and E. D. McCormack, Toronto; J. W. Pilcher, Montreal; M. B. Lovell, Coaticook; H. E. Allen, Waterloo, Que.; H. E. Channell, Stanstead; Chas. E. Taylor, Montreal, E. Craig, Montreal; Gordon J. Henderson, Hamilton; A. W. Staveley, P. H. Davidson and J. R. Meadcroft, Montreal; A L. Breithaupt, Berlin, Ont.; J. K. Johnstone, and J. J. Ashworth, Toronto; W. F. Dean, Thomas Rodger, D. S. Barton, Jas. Hunter, Charles D. Matthews, and H. C. Ross, Montreal; George D. Ellis, Barrie; W. Ahearn, jr., W. G. Bradley and Ed. J. O'Reilly, Ottawa; J. W. Martin, Hamilton; H. W. McLaren, Montreal; E. B. Biggar, J. J. Wright and A. B. Smith, Toronto; Fred Thompson, Montreal; Wm. McCaffrey and Walker G. Anderson, Toronto; J. W. Purcell, Walkerville; C. E. A. Carr, London, Ont.; C. L. Weeks, Toronto; J. R. Wilkes, J. E. Scott and James Kent, Montreal; D. A. Starr, Cornwall; Wm. Campbell, Montreal; C. Thomson, Ottawa; S. Noxon, Ingersoll; P. Morgan, B. F. Reesor, Thos. Sadler and D. McGibbon, Lindsay; G. A. Powell, St. Catharines; R. E. T. Pringle and F. H. Leonard, jr., Montreal; E. E. Cary, St. Catharines; M. P. Cochrane and W. E. Gower, Montreal; Geo. H. Hill, L. Rousseau, Montreal; W. R. Leet, Danville; C. H. Mortimer, Toronto; Henry B. Haigh, New York; L. Robinson and John T. Murphy, Montreal; Robt. Welsford, England; W. F. Simms, Kingston; R. Stanton Wright, Ernest J. Jenking and M. Rubenstein, Montreal· Geo. Black, Hamilton; W. F. McLaren, R. F. Morkill, W. J. Plews, L. A. Howland, J. Fleet and J. W. Morris, Montreal; F. A. Wunder, New York; J. A. Burns, Geo. E. Matthews and Edward Carter, Montreal; W. A. Johnson, Toronto; E. A. Wallberg and R. A. Ross, Montreal; H. G. McLaren, London, Eng.

After "the Queen" had been loyally drunk, the secretary read several letters of regret from absent friends and members, among which was one from F. C. Armstrong, who was then on his way to England, but who desired to assure the company that his thoughts would be with them this evening. Mr. Browne departed from the programme for a moment to propose the health of Mr. Armstrong and wish him prosperity in his new and important field of work, and the rousing enthusiasm with which the toast was received showed how many warm friends Mr. Armstrong had around these tables. "He's a Jolly Good Fellow," was at no time more heartily sung. The chairman then proposed "Electrical Montreal," and coupled with it the name of Mayor Prefontaine, who, he said, ought to be made an honorary member of this association, as His Worship was the projector and proprietor of an electric plant at Ste. Agathe.

The mayor, who was received with hearty enthusiasm, said he would have hesitated somewhat at responding to what was really the toast of the evening had it not been that to some extent he was connected with the electric service. The importance of electricity among the sciences was apparent to all, and it was gratifying to him that so many French names, such for instance, as Ampere, were written in the history of that science. Referring more particularly to Montreal he ventured to say that this city with its population of over 300,000, including suburbs, had made a record that would compare with any city in the world. The pioneer company in Montreal was the Royal Electric Company, which began in 1884 with a dynamo of 12 arc lights capacity and a dozen employees, with a capital of less than $50,000 To-day this company was serving from its two generating stations electric current for 1,500 arc lights, 75,000 incandescent lights, besides 2,000 h.p. in motors. Its new factory has an area of 40,000 square feet, it has over 5,000 employees, and a capital of $2,500,000. In July, 1886, the city gave an order for 133 arc lights for street lighting, which was considered a big contract then, but to-day the city has nearly 1,500 arc lights. One of the latest contracts of the Royal Electric Company is to supply current to the Dominion Cotton Mills Co., to the extent of 1,500 h.p. to operate their large cotton mills in Montreal. The Chambly Manufacturing Company, by which current will be transmitted from the Richelieu River to Montreal by September next, represents a development of 20,000 h.p. He was one of the original promoters of this company, having got its charter through the legislature, and so foolish was the scheme considered that his action in the matter was put down to a desire to win a few votes at the next election. But now this great power is practically ready for trans-

mission. Another enterprise which was a credit to Montreal was the Lachine Hydraulic Works; with a capital of nearly $2,500,000, which has harnessed the St. Lawrence. The enterprise was a vast one. It might not be the complete success at the present time which its promoters expected, but that it would ultimately be a success no one doubted; and it would be a credit not only to the city, but to the gentlemen who had carried out such a big enterprise. In 1892 the Street Railway began operations by electric power, which was first generated at the power house of the Royal Electric Company, with two dynamos of about 500 horse-power; to-day it had 80 miles of track and a plant of about 10,000 horse-power, including an engine built by the Laurie Engine Company, of about 4,000 h.p., one of the largest steam engines in use. In 1894 the Montreal Park & Island Railway Company began operations, and to-day it was running to Back River, St. Laurent, Outremont, Cartierville, etc., and was operating about sixty cars. There were about 8,000 telephones in use in the city, exclusive of about 1,200 belonging to the Merchants' Telephone Company, so that the progress of electrical science in Montreal could easily be seen. He concluded by congratulating the association on the good work it was doing, and said he wished to become a member. The mayor was given three rousing cheers. J. R. Wilkes here sang "The Clang of the Forge," and was heartily encored. The toast of "Our Association" was followed by two comic songs from F. S. Hickey, who made himself a favorite at once. "Sister Associations" followed and R. H. Bartholomew sang "The Anchor's Weighed," and in reply to a hearty encore sang "Maid of Athens." "Our Guests" was replied to by Hon. Senator Thibaudeau, who in acknowledging the honor done him, said, the gentlemen he saw around were the representatives of what was most distinguished in the electrical world. It was to them that Canada owed its great strides in putting into operation the electrical force which had transformed all around us; it was to their energy that everything had been metamorphosed in the Dominion; it was to their accumulation of science that we had to-day those conveniences which contributed to the happiness of this nineteenth century, such as electric tramways, electrical power apparatus, telephones, the lighting so good and so brilliant that one could almost see his conscience better than he could with the "X" rays of the Christian teaching. Montreal had felt the magnetic impulse. The Lachine Hydraulic Works, which they had seen that afternoon in their grandeur, and the Chambly Works, which they would visit the next day, would tell them more about electrical progress in Montreal than he could. These works would tell them that the electricians of Montreal well deserved to be members of their association, and were a credit both to the association, and to the city of Montreal. The electricians of Montreal were jolly good fellows; they might ground a wire now and then, but they were seldom grounded themselves. (Laughter and applause). They also had their periods of incandescence, but it was with a good motive. In conclusion, he wished the Canadian Electrical Association and its members every success. Dr. Drummond was then called upon and gave the habitant's description of summer from his well-known book "The Habitant." At its conclusion there were clamorous calls for the "Pap'neau Gun" which was recited with fine effect. E. I. Jenking then gave a song, which was encored. The president proposed "Electrical Research," and coupled the toast with the name of W. H. Browne, who was not "general manager" tonight, but "one of the boys." Mr. Browne, who was received with "He's a Jolly Good Fellow," regretted the absence of Prof. Herdt, the able scientist of McGill, who was to have replied to the toast, but who was kept away by the serious illness of his wife. Disclaiming any pretensions to science himself he nevertheless spoke entertainingly of the advance of electricity within the past few years. It was only ten years ago that the first electric railway—a pioneer enterprise with which he was connected—began operations, while to-day there were 80 miles of track in this city alone. When hotels were being fitted up with electric curling irons in each room for the lady guests, what developments might we not expect in the near future. The farmer who now could grind his corn, chop his fodder, etc., by electricity, might soon be able to milk his cows electrically. Some one suggested that the day would come when we should eat, sleep, walk and talk electrically and man would thus become an automaton governed entirely by electricity —but, of course, we wished to defer that day as long as we could. (Laughter.) Messrs. Campbell and Starr then gave a duet which was well received and encored. "Allied Interests" was responded to by Ald. G. W. Sadler, of Sadler & Howarth, Montreal; E. E. Cary, of the Packard Electric Co., St. Catharines; C. Lord Weeks, Toronto, and Duncan Macdonald, superintendent of the Montreal Street Railway. Mr. Sadler referred to the fears of some manufacturers that their business would be wiped out when electricity came into general use, but to-day these lines of business are not only thriving but new lines have

WM. H. BROWNE, PRESIDENT CANADIAN ELECTRICAL ASSOCIATION.

been created, due to electrical development. He referred to the first electrical exhibition in Montreal, and suggested that exhibitions should be held in connection with future conventions. Mr. Weeks entertained the company with some humorisms, and Mr. Cary, who followed, showed how the evolution of electrical work in Canada had opened a field for specialists in manufacturing, and their success had shown that the progress of the country was steady and rapid. The three years he had spent in Canada were the happiest of the fourteen years in which he had been engaged in electrical work. Mr. Macdonald humorously sketched the difficulties of a street railway company. If anything goes wrong in the city the street railway is blamed. If the cars go too slow it is their fault, if they go too fast it is their fault all the same. Speaking of the progress of electricity he believed it would continue and perhaps be surpassed by the rising "generators." If our nearest ancestors could return from their graves and view the improvements and enjoy the blessings brought about by this science they would be astounded, and would lavish praise upon the electricians. In fact they can be called the Deweys of this generation. If the association returned with its convention to Montreal it would be greeted with a thousand welcomes. Mr. Kammerer was then called on and amused "the boys" with a funny story, after which Mr. Wilkes sang "Loch Lomond." "The Press" and the "Ladies" concluded the evening, the latter being replied to by Dr. Drummond, who recited the heroic episode of Madelaine Vercheres. The company separated at 1.30 a. m.

Thursday, June 30th.

The first business of the morning was the election of officers, all except the new members of the Executive being returned by acclamation. Mr. Hunt was nominated for president but declined to stand. The result was as follows:

President—W. H. Browne, general manager Royal Electric Co., Montreal.

First Vice-President—H. P. Dwight, president and general manager Great North-Western Telegraph Company, Toronto.

Second Vice-President—A. A. Dion, Ottawa Electric Co., Ottawa.

Secretary-Treasurer—C. H. Mortimer, Toronto.

Committee—J. J. Wright, Toronto; John Carroll, Montreal; O. Higman, Ottawa; A. B. Smith, Toronto; Wm. Thompson, Montreal; W. McLea Walbank, Montreal; E. E. Cary, St. Catharines; Gordon J. Henderson, Hamilton; H. R. Leyden, Hamilton; George Black, Hamilton.

On moving the new president into the chair the thanks of the association were tendered to ex-President Yule, whose urbanity, tireless industry and sound common sense had done so much to advance the association in public estimation during the two years in which he had held office. A hearty vote of thanks was also passed to the members of the local committee and to the various companies who had shown their hospitality on such a munificent scale. The members then went to visit the electrical and mechanical departments of McGill University, where the numerous electrical machines and delicately adjusted instruments were explained by Prof. Herdt with a lucidity that greatly impressed the visitors. The inspection was concluded by a visit to the physics buildings, where an interesting demonstration of X-rays phenomena was given by Mr. King.

The afternoon was taken up with a visit to the extensive works of the Royal Electric Co., where among a multitude of other work in process of manufacture the visitors saw parts of the big generator now being made for the Cataract Power Co., of Hamilton. From here the company went to Bonaventure station where a special G. T. R. train of four cars was in waiting to take them to Chambly, to see the works of the Chambly Manufacturing Company. Anticipating a large excursion the Chambly Manufacturing Company had requisitioned every vehicle in the town to convey the party from the station to the works. There were cabs and calashes, cabriolets and broughams, grocery wagons and butcher carts, market wagons and buckboards, in all conditions of repair and with all conceivable styles of upholstery. The cavalcade was greeted with cheers and the attack on Santiago was nothing to the storming of these vehicles. The scenery of the quaint old village of Chambly was much enjoyed, and so was the visit to the great dam and power house which have both been described in recent numbers of The Canadian Engineer. The venerable but still active president of the company, S. T. Willett, who has been elected mayor of Chambly continuously since 1873, was present to welcome the visitors, and did it with the sincerity so characteristic of him. After being photographed in a group the visitors were called into the upper story of the power house and beheld a table of interminable length spread with immense dishes of cold meats, confectionery, strawberries and cream, lemonade, claret cups, etc. To say that "full justice" was done to these provisions would be putting it mildly. Mr. Willett, who occupied the chair, welcomed the members and their ladies, and credited the electrical science with the transformation which was now being made in the town and its prospects. Hon. Senator Thibaudeau made a short speech of welcome which was well received, especially by the ladies whom he complimented with a gallantry so natural to a French Canadian. Mr. Browne followed with a few words of welcome on behalf of the Royal Electric Co., referring to the fact that beneath their feet the Chambly Co. had harnessed 20,000 h.p. where the shallows of a river had been running to waste for ages past. On behalf of the association Mr. Dion thanked the company for the handsome entertainment and excursion, which the members enjoyed, and the party returned to the city delighted with their trip, which formed such a pleasant finale to the convention.

A. A. Dion, 2nd vice-president Canadian Electrical Association, was born and educated in the city of Quebec. He commenced his electrical career in the service of the old Dominion Telegraph Co., in 1876. After filling various positions and engaging in railway work for a few years, he was appointed electrician for the Intercolonial Railway system of Canada in 1889. He resigned in 1891 to take the superintendency of the Chaudiere Electric Light & Power Co., of Ottawa, a position which he filled until 1894, when the amalgamation of the three

A. A. DION.

lighting companies doing business in Ottawa took place, when he was made general superintendent of the amalgamated companies known as the Ottawa Electric Company, which position he now holds. Mr. Dion was a member of the Executive Committee of the Canadian Electrical Association for 1897-98. He is a member of the American Institute of Electrical Engineers.

CONVENTION NOTES.

Taken as a whole the convention was the most successful in the history of the association. About 50 new members were elected, chiefly from Montreal and vicinity, and these were not drummed up, but were men who came in from a natural interest in the work of the association.

Secretary Mortimer had a good deal of work to do and got through it very creditably. Mr. Mortimer has one good quality among others, and that is he never fails in civility and courtesy.

The Packard Electric Co., of St. Catharines, kept open house at rooms 11 and 12 in the Windsor, and all were made royally welcome. Their Montreal branch was illuminated and the crowd of conventioners gave three cheers when they passed the place on one of their city trips.

Ald. Sadler's suggestion of an exhibition of electrical machinery in connection with the next convention was a good one, and is worth early discussion. The Packard Electric Co. made a little start on its own account by showing the sections of their new transformer and other goods in their rooms.

Mr. Kammerer gave the members a pretty souvenir in the shape of a little silk bow formed of the Union Jack on one side and the Stars and Stripes on the other. In bestowing it Mr. Kammerer did not forget the ladies. He never does.

"These gentlemen," said The Witness in one of its notes, "are adepts at 'stringing wires,' but it is pleasing to note that they do not—at least at association meetings—go in for 'pulling wires,' for official positions are filled with a view to the advantage of the association.

Among the American visitors was F. A. Wunder, of the New York office of the Fort Wayne Electric corporation. Mr. Wunder was pleased with what he saw in and around Montreal, and is generously leaving a memento of his visit in the shape of one of the company's Watt-hour meters, which will be presented to McGill University. Reference will be made to this in The Canadian Engineer. Besides Mr. Wunder, Mr. Quimby, the inventor of the Quimby screw pump, and Mr. McLaughlin, of The Electrical World, were present from over the border.

Too much praise cannot be given to the individuals who formed the Entertainment Committee and the companies who so liberally contributed their work and money to aid them. It is only another good illustration of the saying that when Montreal men undertake a thing of this kind they do it well.

The Canadian General Electric Co. had what the boys called a very "nifty" idea in the form of a nickel-plated model of a C. G. E. motor to be used as a paper-weight. It was much appreciated by members as a souvenir.

Among the many attractive points in Montreal during the convention, that of John Murphy & Co.'s store, where John Forman made an exhibit of the Upton Midget Enclosed Arc Lamps, held the attention of the delegates probably

as much as anything they had seen. This shop has lately had installed a large number of these lamps, having discarded their old style of arc lighting, and in some places done away with the Auer Incandescent Gas Light, and arranged to have the whole establishment lit with the Upton Midget Enclosed Arc Lamp. After a very careful test of the various lamps of different manufacture in the market, they concluded that the Upton was by far the most economical system of lighting to be had. This store, which is situated on St. Catharine street, (Montreal's principal thoroughfare), has fitted in the fourteen large windows fourteen of the Upton lamps, each arranged with a special bell mouthed shade, and though these lamps are taking but 4½ amperes on 100-volt circuit, the illumination far surpasses some of the window lighting on the same street where ten and fifteen incandescent lamps are used in handsome reflectors on 52 volt circuit, where each lamp would be drawing 1 ampere. In the case of the incandescent, 15 lamps would be drawing 15 amperes of current and giving 240 candle-power, while with one-third of the amount of current on the Upton Midget, the latter were giving 800 candle power, or practically three times as much. Not the least important point in this installation was the fact that the lamps which were ordered from John Forman, 644 Craig street, Montreal, on Wednesday the 22nd, were ordered on from the States, while handsome fixtures were being manufactured in Montreal for the installation, and the whole was in satisfactory working condition on Monday the 27th.

LAUNCH OF THE TORONTO.

Every circumstance favored the ceremony of launching the new Richelieu & Ontario Navigation Co.'s steamer "Toronto," which took place from the shipyards of the Bertram Engine Works Co., on the afternoon of June 21st. A clear, bright day, with a westerly breeze, brought out dozens of sailing craft and row boats, as well as some steam yachts, to view the first floating of the finest steamer ever built in Toronto. The decks of the steamer "White Star" were crowded with citizens who had come at the invitation of the Bertram Co., to view the launching, and about four o'clock the steamer lay to at the inner end of the Eastern Gap, opposite the shipyard where the new vessel stood braced up from stem to stern as if conscious of the impending event and eager to make the plunge. The supports having been knocked away, Madame Forget, wife of Senator Forget, president of the R. & O. Nav. Co., broke a bottle of wine on the bows of the new boat, christening her the "Toronto." A. Angstrom, constructing engineer and designer of the boat gave the command "let go," and when the last block was knocked away the handsome vessel, gay with

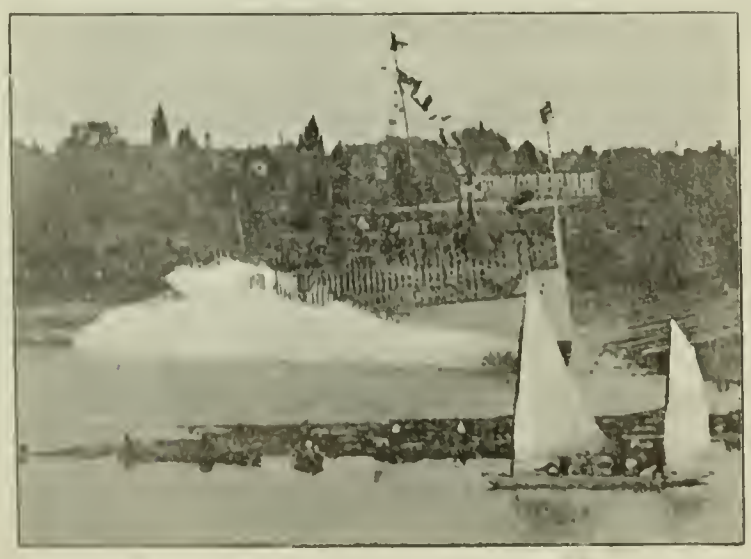

Photo by N. T. Maclaurin, amateur.

THE "TORONTO."

flags and streamers, slipped gracefully down the ways, dropped into the water with a lurch that sent the spray into the air in a vast cloud, and then she bounded upward "as a steed that knows his rider," shaking the water from her decks like a duck and then settled with a buoyant air on her native element. The large crowd upon the docks and on the steamers and boats set up a cheer at the neatness of the performance and the pretty outlines of the boat, while the band on the "White Star" played "Britannia Rules the Waves." The "White Star" then drew off into the bay, where congratulatory speeches were delivered, J. K. Osborne, one of the western directors of the Richelieu Co., presiding. Among the speakers were Sir Oliver Mowat, Senator Forget, Col. Henshaw, Mayor Shaw and Geo. H. Bertram, M. P. C. F. Gildersleeve, the general manager of the Richelieu Co., was present at the function. The company was entertained at a champagne luncheon by Mr. Bertram.

The new steamer, which will probably be ready for "sea" some time in September, will cost $240,000 exclusive of furniture and fittings, or about $275,000 in all, is guaranteed to make an average speed of 17 miles per hour on regular trips, but her estimated power will give 20 miles per hour when pushed. The following is a brief description of her:

The hull, constructed of open hearth steel, and of the following dimensions: Length over-all, 278 feet; length keel, 270 feet; beam, moulded, 36 feet; beam, over-guards, 62 feet; depth, moulded, 14 feet. The engines are of the triple expansion, inclined jet condensing type; cylinders, 28, 44 and 74 inches by 72 inch stroke. The feathering paddle wheels are 22 feet outside diameter, and 10 feet 3 inch face of bucket. The air and feed pumps are attached to and worked from main engine. The boilers are four in number and are of the return tubular type, 11 feet diameter, and 11 feet 6 inches long over heads. Each boiler has two 41½ inch outside diameter Monsom suspension furnaces. The boilers are fitted with the Howden Hot Draft, and are designed for a working pressure of 176 pounds. Spacious and elegant passenger accommodations are provided, one hundred and forty staterooms, including four parlor rooms and large Pullman sleeping cabin, furnish sleeping accommodation for 430 passengers. The dining room, placed on the upper deck, has a seating capacity for over a hundred persons. The interior finish and decorations of the spacious halls and deck saloons, are most elaborately executed, the main and gallery saloons being finished in Francis I. Renaissance style, with the dining rooms in Louis XVI. The entrance hall is decorated in Neo Grec, with modern Renaissance details, with the smoking room in Oriental treatment. The refreshment and writing rooms will be in Elizabethan panelling of prima-vera, natural wood finish. The main staircases are Honduras mahogany, with wrought metal balustrades, in hammered leaf work, finished in antique bronze, the main newels carrying bronze figures supporting electric torches. A 700-light electric light plant, with ornamental electroliers, in cabins furnishes light throughout the steamer.

ROPE DRIVING.

The subject of rope driving has so far received little or no attention at the hands of our Canadian engineering journals, in fact, we may safely say, that even in the United States, this is a subject touched upon very sparingly by the trade papers, and mechanical publications generally. We fancy the reason of this is that rope driving is a branch of mechanics not so generally taken up by the ordinary run of engineers and machinists, but is as yet more of a specialty, and has so far only been advocated strongly or to any extent by one Canadian firm, the Dodge Company, of Toronto. We believe that rope driving has a field of its own, and is not necessarily a competitor of the belt manufacturers as has been supposed. We have called at the office of the Dodge Co., Toronto, and have learned the particulars of a very interesting piece of work recently completed at the works of the Globe File Mfg. Co., Port Hope, Ont., by the Dodge Co., Toronto. In this instance the power of three 40" Leffel water wheels, under a 12' head, had been transmitted to the line shafts in shops, by means of bevel gears and crown wheels, on ends of upright shafts from water wheels—power taken from each wheel being about 40 h.p. In one case there were used a pair of bevel gears to carry the power of one of the wheels to a shaft at right angles to the others. In all three upright shafts there was a continual trouble in keeping them in line, owing to the great strain on their upper end, also in the case of the geared shaft at right angles, there was a continual jam either against the boxes, or the pinion on crown gears, thus consuming too large a percentage of the power. The crown wheel on No. 1 shaft had to be re-toothed as often as every two weeks, on No. 3 shaft every three months, and on No. 2 shaft two or three times a year, so that on the whole the power was unsteady, and much time was lost in re-toothing wheels and keeping them in proper alignment. In addition to this the noise from the gears was deafening, and the dirt from oil

dropping, etc., created a nuisance. With a view of a remedy the Globe File Co. therefore consulted the Dodge Co., and after the latter company's engineer had made a thorough inspection of the plant, a plan was devised to dispose of all the gears, and to transmit the power of the three wheels to the different line shafts by a system of rope transmission. The Dodge Co.'s men made the change and started up under the new rig without a hitch.

As to how the change has suited the Globe File Co., the Dodge Co. has shown us a copy of a letter recently received by them from F. Outram, the manager, he says: "As regards the three rope drivers you put in for us, they are working to our entire satisfaction. We know we are saving considerable power, besides doing away with the noise and rattle and wearing out of wood and iron gears—and it is ever so much cleaner. We would not change back for five times what the change cost us."

Yours truly,
Globe File Mfg. Co.

This letter goes to show that there are many instances to which the rope drive is particularly suited.

There are two systems of rope driving, i.e., what is known as the "American" or single continuous rope with an automatic take up or tightener, and the "English" system, which is a series of independent ropes. The former is the system advocated by the Dodge Co. We understand that some of our largest plants in Canada are run altogether by ropes, and they are found to be economical. The E. B. Eddy Co., of Hull, Quebec, is a great believer in the rope drive, and has several thousand horse power in daily use, installed by this company.

For THE CANADIAN ENGINEER.

FUTURE OF MECHANICAL TRACTION.

As to the future of the autocar industry, space does not permit of more than the briefest summary. The problem of transportation is the largest and most pressing in Canada to-day; whether we view the matter from the standpoint of convenience, speed, good roads or expenditure, the autocar looms up as a most important factor in the problem. Let us summarize a few facts.

The average cost of transport to-day of goods between Liverpool and Manchester, a distance of 35 miles, is over $2.25 per ton, the quantities to be conveyed being at least 15,000 tons per week. There are railways and there is the new and magnificent canal, and yet shippers demand a better and cheaper means of transport; for it must be remembered that although the rates must be high on account of the enormous capital account, both by water and rail, the carrying is not terminal, and three or four trans-shipments are involved in every bale of goods. By a light railway system, which would be inexpensive, compared with the ordinary railway and canal, motor wagons might utilize rails for the greater distance and run off the rail on to ordinary roads at the termini; the goods thus being handled only at each end when being loaded and unloaded, and a large item in the cost thereby saved. With all that can be done by railways or tramways, there are millions of tons of passengers and goods to be provided for between railway stations and destinations. Worby Beaumont, president of the Society of Engineers, points out that "it is not generally known that to-day it costs more to send a ton of goods by rail between some places in this country (England), than it cost formerly to send it by horse on the common roads. . . . The cost of haulage by rail is very small, but the terminal cost and cost of railway establishments, as vast machines, are so heavy, that the cheapness of railway transit disappears." He also points out that the British post office finds it cheaper to send its parcels by road than to pay the rates demanded by the railway companies for that traffic. When the comparatively small cost of autocar and motor wagon equipment for passenger and freight purposes is compared with the immense initial cost of railways, ordinary tramways, and canals, it will be seen that just as surely as the horse-cars have given place to the trolley, so surely must the heavy and expensive cars and rails, with the enormous funds required for maintenance, interest charges, etc., give way to the lighter, cheaper, and easily adaptable system of autocars.

In large cities, such as London, the question of space is another important factor. As Mr. Beaumont points out, there is such a density of traffic in London that nothing but the short-distance passenger accommodation must be allowed in the streets, either by tramcar or omnibus. "As early as possible," he says, "the motor cabs and omnibuses must displace horses so as to save the space now occupied by them, and avoid the pounding to pieces of the wood, asphalt and other of the best pavements with the 300-weight hammers of iron-shod horses' feet." He reckons that at least one-third of the space now occupied by the horses can be saved by the employment of motor vehicles. Some idea can be gathered of the pressure on London streets when it is remembered that every 24 hours

	Persons.		Vehicles.
Blackfriars Bridge discharges	69,838	and	8,287
London Bridge discharges	107,421	and	14,367

Then the cost of horses is in itself a very large item. Mr. Beaumont gives a calculation in which he shows that in Great Britain there are at present about 1,200,000 draught horses employed; but assuming that only 500,000 are at work, taking only the cost of keeping these horses, and saying nothing of the destruction to roads, the improvements in the roads which he recommends would result in a saving of £30 per year per horse, or a total of £5,100,000, which capitalized at three per cent. represents £170,000,000 sterling. He argues, "There is no doubt that such a sum might profitably be invested in the roads of Great Britain if we consider the advantages to be derived from mechanical traction."

The solution of the question of transport between towns does not necessarily lie in the direction of street railways or tramways, which Mr. Beaumont emphatically pronounces, "metallic admissions by engineers to the public of the badness of the ordinary roads." He adds that in the future of good roads, "Tram-rails in our streets will be considered nuisances not to be tolerated;" and "the days of toleration only wait for those mechanical road vehicles to prove plentiful as well as successful."

There is no reason, indeed, why the motor wagon enthusiasts should not carry their war into Africa, if they can only get engines with sufficient power; for the power directly applied to the driving wheels of autocars, and the immense tractive power of good roads, as compared with rails, put railcars at a disadvantage, when it comes to the cost of equipment and running. With 6,000 h.p. developed at the power house of a street railway company, the cars can only get what tractive effort the wheels will give them on the line. This is the weak link in the chain. In the case of a snow drift, for example, a motor car with spiked wheels would be able to overcome the obstacle better than the strongest street car plough. With the cars coupled up as they are to-day, the front car is never doing satisfactory work, because it is insulated by the snow, and therefore not getting power. Every few feet it has to be drawn out by the other cars. In the case of motor cars on the roads, they could not be insulated, and a set of three autocars, if hitched together, could be made to develop a total of 60 horse-power steadily applied, with a tractive pull of three tons.

Another element in the discussion of mechanical traction is that of danger to life and limb. In Britain the newspapers make "scare-heads" over every item in reference to accidents to motor carriages and their occupants, but never use the "deadly parallel" in showing the relative danger of motors and horses. In England and France there have been three deaths in connection with motor vehicles—all caused by recklessness and carelessness. The following record of accidents and deaths from horses in the vicinity of Toronto alone during two months is far more appalling:

Killed:—April 9th, Wm. J. Fenton, dentist, Toronto, horse frightened by watering-cart; 16th, Chas. Ralston, farmer, Walkerton, horse frightened by bicycle; 17th, Edward Lee, farmer, London; 19th, Isaac Ferris, St. Mary's, horse frightened by train; 23rd, Thos. Robinson, Omemee. May 1st, Joseph Bailey, farmer, Walkerton; 8th, Dalton McCarthy, M.P., Toronto, horse frightened by sound of church organ; 25th, Anthony Hurley, farmer, Eastwood, horses frightened by railway train. Total number killed in two months—8. Injured:—April 4th, son of David Hastings, Blenheim, badly injured; 16th, son of Chas. Ralston injured (father killed as

above); May 1st, London omnibus party, several ladies hurt; same date son of Joseph Bailey injured (father killed as above). Total number injured, 7.

A closing word as to the present position of the industry. In France, the home of the autocar (or automobile, as it is called by the French), the industry is going forward rapidly. The principal makers, of whom there are only about four who stand out beyond the general trade, are overcrowded with orders, and some firms are refusing them. Panhard & Levassor, in a recent fortnight, booked $150,000 worth of orders. In Britain, while we write, the trials of mechanical vehicles for heavy traffic are taking place, and the War and Post Office departments are watching them with interest. The industry is slowly emerging from the disastrous stock-jobbing which characterized its early days, and is getting on a business footing. The successful journey of Mr. Sturmey, editor of The Autocar, from John O'Groat's to Land's End, has helped to popularize the autocar, as showing what it is capable of. In the United States, the movement is slower than anywhere else, largely, we presume on account of the bad roads. Col. Pope has been bravely spending money in experiments with electricity, but the Pope electrical carriage has not yet been brought into general use. The Duryea carriage, which won the Chicago Times-Herald race, and the $3,000 Cosmopolitan prize at New York, does not seem to have recovered from the dazing effects of success, for we hear and see little of it now, though it is being manufactured in Springfield, Mass. The Winton, of Cleveland, is being pushed with some energy, and the inventor offers to put up $1,000 on a race from Chicago to New York, but stipulates that competing carriages shall carry only two passengers—which looks as though the Winton lacked the essential element of power, as do the other American motors.

The most important recent event is the heavy autocar trials at Liverpool, May 24th—28th, of which we give a summary. As a result, Messrs. Thornycroft are pushing the erection of an extensive factory for autocar manufacturing, at Basingstroke, while the Liquid Fuel Engineering Co. is selecting extensive premises in the Midlands for works for 500 or 600 hands, who will be employed solely in constructing "Lifu" cars.

HEAVY CLASS (FIVE TONS MINIMUM)—ONE ENTRY.

1. Thornycroft Lorry.—Steam Carriage and Wagon Co., Ltd., Chiswick. 6 wheels. Load carried by rear pair of wheels on platform resting on turn-table fixed over the rear wheels of the front portion of the vehicle, allowing motion in two places, so that wheel base could accommodate itself to road inequalities. Speed 5 miles an hour. Available floor space, 110 sq. ft. Tare (English) 3 tons 19½ cwt. (light); with fuel and water, in running order, 4 tons 5 cwt. Underframe and wheels of steel; roller bearings. Heating surface of water tube boiler, 65 sq. ft. Grate area, 2½ sq. ft. Test pressure 350 lbs. per sq. in. Fuel, steam—coal or coke. Engine horizontal compound with cylinders 4 and 7 in. by 5 in. Condenser of small copper tubes brazed together on roof of driver's cab silences exhaust, and blow-off from safety valve. Gearing has two speeds, engine making 9 or 12 revolutions to one of driving wheels. Powerful screw-down hand brake fitted to tires of driving wheels, and independent steam brake with pressure of 2¼ tons acts on wheels of trailing body.

LIGHT CLASS (TWO TONS MINIMUM)—THREE ENTRIES.

1. Thornycroft Car.—Tare, 2 tons 19 cwt. light, in running order, with fuel and water, 3 tons, 4½ cwt. Speed 6 to 8 miles per hour. Boiler, engine and mechanical details same as above, but gearing gives ratio of 8 to 1 from engine to driving wheels.

2. Leyland Van.—Lancashire Steam Motor Co. Platform area 78 sq. ft. Boiler, fire-tube type, with 110 sq. ft. heating surface. Weight, per sq. ft. of surface, is 6 lbs. Working pressure 200 lbs., tested to 450 hydraulically. Steam, which can be raised to working pressure in 18 minutes, is generated by liquid fuel, supply regulated by pressure on boiler, making firing automatic. Condensers on roof of cab make it unnecessary to carry any great quantity of water. In full work burns 1¾ gals. of oil per hour, costing 3½d. per gal. Inside of boiler can be lifted out for cleaning without removing any steam fittings.

3. Lifu Lorry.—Liquid Fuel Engineering Co., Cowes. 16 ft. 2 in. long, 6 ft. 6 in. wide over hubs. Wheels have bronze hubs, fitted with large reservoirs for lubrication. Steering by a handle connected to pivoted axles. Engine compound reversible, runs at 600 revolutions for speed of 8 miles per hour, geared down from 8 to 1. Water-tube boiler, 80 sq. ft. heating surface, capable of making sufficient steam to supply an engine indicating 35 h.p., and will easily indicate 25 h.p. without forcing. Boiler tested to 500 lbs. hyd. pressure, and safety valve set for working pressure of 250 lbs. per sq. in. Supply of oil to patent Lifu burner is automatically regulated by steam pressure in boiler, and set to ease the fire down at 225 lbs. pressure. Regulation of speed by means of h.p. cylinder valve, but when extra power required, high pressure steam is let into the h.p. cylinder. Brakes by reversing, also by foot brake, by steel bands around large gears fastened to rear wheels. Sand boxes are provided for greasy roads, and worked from driver's seat. Two oil tanks of 20 gals. each. Two water tanks, one of 60 gals., under driver's seat, one of 75 gals. under platform, are filled by steam injector. Weight of vehicle, without fuel or water, 38½ cwt.; with full supply, 54 cwt.; speed, 8 miles per hour on fair roads when fully loaded, and can climb grades 1 in 10 at 4 miles per hour.

The cars were loaded up with bags of gravel, and in addition to the "crew" were two "official observers" on each car, while another set of "observers" were placed in charge of the depot. The judges were: Sir David Salmons, Boverton Redwood, F.R.S.E.; Prof. H. E. Hele-Shaw, LL.D., M.I.C.E.; S. B. Cottrell, M.I.C.E., and Henry H. West, M.I.C.E. The competition lasted two days, covering two routes of 40 miles each. Several petroleum-driven smaller vehicles, and a steam wagonette, occupied by interested spectators, accompanied the competitors. The Autocar, to which we are indebted for particulars, says: "The Thornycroft five-tonner led off at a trot, with the Lifu bringing up the rear and dashing away in fine style after the rest, its funnel swaying about. . . . .

One incident of the first day's run was the bursting of a tube in the boiler of the Thornycroft 2½-ton van. This occurred when about half the journey had been made, and was undoubtedly due to the tube getting stopped up; a fact probably to be attributed to oil getting mixed with the feed water. The van was going so well, running easily and lightly with its load, and performed so favorably in other respects that it is much to be regretted this mishap should have occurred. The Leyland lorry lost two tires; the Thornycroft six-wheeler was delayed half an hour by getting a wheel stuck. The arrivals at Liverpool were as follows: Lifu, 5 p.m.; Thornycroft, two-tonner, 8 p.m. The Leyland ran after getting its tires put right, but had one wheel go to pieces entirely, and could not get home. Engineering, the well-known London technical journal, says of the end of the first day's trial "The Thornycroft 5-ton load van got in very late indeed, owing to the tire coming off. This was most unfortunate, as the journey was very nearly completed, and the wagon had gone exceedingly well during the day."

The second day's trial resulted in the following order: Lifu, Thornycroft two-tonner, Leyland. The third day the Leyland did not start on account of damaged wheel. The large Thornycroft kept on slow speed all day, and came in about 11 p.m. The fan of the small Thornycroft got out of order near the finish, but she raced home under forced draught. The Lifu had been injured the previous day by a steam carriage running into her, but she pushed through and finished the day's work at 4.30 p.m. On the fourth and last day, the Thornycroft six-wheeler made the run without accident and finished at 11 p.m.; the Leyland came through in good time, as did the smaller Thornycroft. The Lifu stopped twice to take water, and reached home by 3.30 p.m.

WHY THEY SAW NOTHING.

The report of the Canadian Government expedition to Hudson Bay last year has now been published. As was anticipated by those who knew somewhat of the circumstances under which the "Diana" was sent on her mission, the report is as little favorable to the Hudson Bay route as is possible without expressing too conspicuous an animus. It was currently reported in Canada a few years back that the Dominion Government would not take steps to develop the short northern route until the Canadian Pacific had got a fair start. The C.P.R. has not only got on its legs now—it is pretty well dominating the country, and does not mean to have any opposition if it

can help it; and it has particularly set its face against the Hudson Bay route. It was very unfortunate, therefore, that the secretary to the expedition should have been a son of the secretary of the Canadian Pacific Railway, and that before starting on the expedition he should have had an "interview" with the president of the Canadian Pacific. It was even more unfortunate that Captain Wakeham—admirable sailor though he doubtless is—should have been chosen to command the expedition, as he was notoriously inexperienced in ice navigation, and, on his own confession in the report, this inexperience led him into difficulties which hindered his test passage through the strait.—From the London Saturday Review.

THE MASTER PLUMBERS' CONVENTION.

The convention headquarters was at the Hotel Victoria, Quebec. It opened June 29th, and at 10 o'clock a private meeting of the Executive Committee was held, composed of the following: Jos. Wright, Toronto, president; W. Smith, London, vice-president; W. M. Briggs, Montreal, treas.; W. Mansell, Toronto, financial and recording secretary; J. B. Fitzsimmons, Ontario; A. Picard, Quebec; T. Campbell, New Brunswick; G. A. Perrie, Nova Scotia; T. Stevenson, Manitoba, and Jos. Lamarche, Montreal. In the afternoon at 2.15 a general meeting of the convention took place, and at 8 o'clock the business meeting was continued. On Thursday morning all the members attending the convention were photographed in a group, and other business meetings continued till the evening, when a banquet was held at the Victoria, to which the leading civic authorities and architects of the city were invited. Friday morning a drive around the city and different points of interest was indulged in, and a reception tendered the delegates in the City Hall by His Worship, the Mayor of Quebec. On Friday an excursion was made to the shrine of Ste. Anne de Beaupre over the line of the Q. M. & C. R. R. and on returning a stop was made at Montmorency to allow the excursionists to see the Falls. The election of national officers resulted as follows: President, W. Smith, London; vice-pres., J. W. Harris, Montreal; treas., T. Meredith, Toronto; sec., W. Mansell, Toronto; executive committee, A. Fiddes, Toronto; Jos. Lamarche, Montreal; Thos. Campbell, St. John, N. B.; M. Day, Halifax. Provincial vice-presidents, John Highman, Ottawa, for Ontario; E. Lesperance, Montreal, for Quebec; J. Doody, St. John, for New Brunswick; G. A. Perrie, Halifax, for Nova Scotia; W. Stephenson, Winnipeg, for Manitoba; M. J. Barr, Vancouver, for British Columbia.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

At the annual meeting of Kingston branch, No. 10, C.A.S.E., last month, the following officers were elected for the current year: President, C. Asselstine; vice-president, R. Bajies; secretary, J. L. Orr; treasurer, C. Selby; doorkeeper, S. Donnelly; conductor, G. Barrance; trustees, F. Simmons, C. Blomly.

Montreal, No. 1, C.A.S.E., held its annual meeting on the last Monday in May, when the following officers were elected: President, Geo. Hunt; vice-president, Wm. Ware; second vice-president, J. G. Robertson; recording secretary, H. Wilson; financial secretary, H. Nuttall; corresponding secretary, P. McNaughton; treasurer, Thos. Ryan; doorkeeper, John Huntingdon; conductor, Thos. Naiden; trustees, John J. York, John Huntingdon, O. E. Granberg; delegates to convention, Messrs. Huntingdon and Ryan.

The Canadian Association of Stationary Engineers' Unity, No. 5, London, Ont., elected the following officers at the annual meeting: Duncan McKinley, president; W. Blythe, vice-president; G. B. Risler, treasurer; W. Allen, cor. sec.; W. Meaden, rec. sec.; James Harding, conductor; Henry Geldart, guard. The installation of officers was carried out in a very efficient manner by the past president, J. D. Campbell.

The following are the new officers of Toronto, No. 1, C.A.S.E.: President, C. Moseley; vice-president, H. E. Terry; rec. sec., J. W. Marr, Davisville, Ont.; financial sec, A. Slute; treas., S. Thompson; conductor, W. Clark; doorkeeper, J. Long; trustees, J. Huggett, W. Webb, J. Fox. The officers were installed by past president Jno. Fox.

The annual convention of the Canadian Association of Stationary Engineers will be held this year in Hamilton, Ont., beginning on Aug. 8th. A most instructive and entertaining programme is being prepared, and the delegates will certainly enjoy a visit to so important a manufacturing centre as Hamilton.

PATENTS TO CANADIANS.

Fetherstonhaugh & Co., Patent Solicitors, of Toronto and Montreal, furnish us with the following list of patents, relating to machinery or engineering, granted to Canadians in the following countries. Any further information may be readily obtained from them direct.

Canadian Patents.—Amalgamators, M. Cross; wire fence machine, A. H. Cook; apparatus for amalgamating and concentrating precious metals, H. H. Earns; apparatus for the production and storage of acetylene gas, R. F. Carter; water heaters, R. Rushton; hay presses, R. McLoad; swing and slide farm gates, J. Pratt; shaft attachments, N. Green, automatic running board and guard rail combined, on the top of freight cars, J. Carmichael; seed drill disc shoes, N. Stephenson; cradles, C. Gay; straw cutters, A. Johnston; drain ditching plough devices, W. Hawker; valves, C. H. Volmann, liquid fuel burners, C. M. Cookson; machine for weaving wire fence, J. Roch; section valve for automatic fire sprinklers, E. J. Phillip; fire escape, J. McNeil; earth boring augers, Z. Leroux; tension for the binding mechanism of harvester binders, T. H. King; brakes, A. Desbains.

American Patents.—Motor, T. A. Brennan; grappling-hook, T. David; sheet-metal vehicle-wheel tire, J. Jamieson; brake, A. Desbains; thawing apparatus, R. B. Ormiston; pulley, H. S. Pell; electromagnetic-switch railway, A. Norman; vessel and sail and rigging therefor, C. Twining.

WATERPROOF STONEWORK.

What was at first considered a doubtful experiment, viz., the use of coal tar as a means of rendering masonry impervious to water, especially in positions exposed to direct contact with the latter, has proved a practically valuable resort, says Paving and Municipal Engineering. Used as a coating for masonry, built up of very porous stone, tar renders it quite impervious even at a depth of some fifty feet of water, and, according to the opinion of those whose experience has been extensive with it, the article should be utilized in all public buildings, particularly those designed for the preservation of works of art, the dissolving action of water, even upon mortar of superior quality, being well known, and also the unfavorable effect of the exudation of water charged with lime salts from the mortar. Two different methods of using the tar are named, viz., in a boiling state in one or several layers, this being suitable for surfaces exposed to the air, or it may be made to flame up before using, this being appropriate to surfaces which have to be covered up. It is stated that when boiling coal tar is employed in three coats on masonry, the result is a black and very brilliant varnish, which perfectly resists the action of frost, water and sun, being likewise absolutely impervious; and the tendency of the black coating to absorb heat may be overcome by white-dusting the whole before the tar is quite dry.

ELECTRIC POWER AT SAULT STE. MARIE.

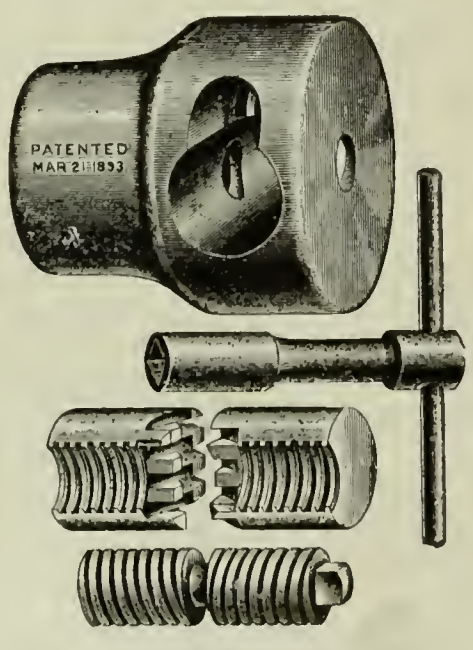
Great things are to be accomplished at the two "Soos," according to F. H. Clergue, president of the Lake Superior Power Company, at Sault Ste. Marie, Ont. Two hundred delegates of the North-West Electrical Convention visited the two towns a short time ago, and Mr. Clergue, addressing the delegates, said: "The Lake Superior Power Company have added to their present investment, the Power Canal at Sault Ste. Marie, Ont., by the purchase of the rights of the abandoned power canal on the American side of the rapids, and have added to the property thus acquired large tracts of land in addition, sufficient to permit of the construction of a hydraulic canal of about 50,000 horse-power. The plans for the construction of this canal have been completed, the specifications have been issued to contractors, and July 1st the tenders will be opened and the contracts awarded. The constructions provided for in the specifications consist of a hydraulic canal 22 feet in depth and 250 feet in width, terminating in a power station constructed of stone, and extending for a distance of

1,200 feet along the water front. This will be the largest hydraulic plant yet constructed, and will contain 80 electrical dynamos, of 500 horse-power each. The cost of this development will exceed $3,000,000, without including the cost of the mills and factories, which will utilize the power thus created. One-half of the entire power generated by the canal has been sold to the Union Carbide Company for a period of 25 years, and the remainder of the power will be devoted to metallurgical uses. The contracts call for the completion of all this work within three years from July 1st, and at its completion it is the intention of the Power Company to continue their operations by large additions to their works on the Canadian side."

Mr. Clergue explained that it was not the intention to begin the construction of a second water power canal on the Canadian side of the river until the end of the work on the American side of the river was completed, which would be in about three years. The new power canal on the Canadian side would have three times the capacity of the present canal, and it would cost about $500,000. The reduction works, which would be constructed at the Canadian Soo, immediately afterward, would not cost less than $1,000,000 more. After the canal and works were completed, the reduction works would give permanent employment to nearly 1,000 men, most of whom would be skilled workmen.

THE HORTON DRILL CHUCK.

As shown by the engraving, this chuck is simple in construction and very strong and durable in all its parts. The body is composed of one piece of metal and the entire chuck of four pieces. Chucks in ¼" and ½" sizes are made of steel, and in the larger sizes the working parts are of steel, the jaws are so constructed that there is no danger of breaking or crimping the drill by gripping as in many drill chucks. The right and left hand screw, which drives the jaws. is set deep



The Horton Drill Chuck

into the latter so that an end thrust with jaws is obtained and consequently a stronger grip with no danger of breaking the screw. The jaws are cylindrical and the power of the screw, being applied more direct, there is no binding or canting of the jaw when taking a short bite, as is the case with the 2 jaw chucks made with the old-fashioned, angular jaw set in a rectangular slotted body. This chuck is made in six sizes, as follows: ¼", ½", ¾", 1", 1½", 2' The 1½" and 2" sizes are attached to the spindle of the machine by means of a face-plate and screws, the same as an ordinary lathe chuck. These chucks may be had from the Aikenhead Hardware Co., 6 Adelaide St. East, Toronto.

TIDAL MOTORS.

Editor Canadian Engineer :

Sir,—An article under the heading "The old Tide Mills of Brooklyn," at page 371, of June 11th No. of the Scientific American for 1898, leads me to wonder how engineers are and have been striving after some ingenious automatic float arrangement for utilizing the force stored up in and to be had from the daily rise of tides in Canada and other parts of the world, when it would seem to be so much more simple to follow the practice of by-gone ages, by damming up the water as the Hollanders of yore did at Brooklyn. And if the practice paid there, where the tides, I believe, rise but a few feet, how much more prolific would they not be along the St. Lawrence below Three Rivers, where, as at Quebec, the neaps are 14 feet, and the springs as much as 22 or more; or again, in the Bay of Fundy, N.S., where the rise varies from 30 to 60 feet.

To get sufficient power from a float, it must evidently be of very large size, and therefore, the larger the more expensive; the price increasing as the area or square of its dimensions—while in the barring of a creek or ravine or mouth of a tidal river, the cost would be enhanced only in the ratio of the length of dam, the area of water enclosed increasing in almost any ratio. It would therefore seem that the simplest and most economical mode of utilizing the rise of the tide would be to proceed as in the impounding of water for an aqueduct; establishing all along the face of the dam a series of automatic gates, opening to the rising water and closing at ebb; when side issues from such a body and bearing only a relatively small proportion to the bulk of water held up, could be utilized either through turbines or undershot wheels for a variety of purposes.

Chas. Baillarge, C.E.

It is now about three years since the Syracuse Smelting Works first introduced their Syracuse babbitt metal into Canada. It has since been giving great satisfaction, so that they have been constantly asked by numbers of their large customers to start works in Canada. They have at last done so, and have established works on the corner of St. Thomas and William sts, opposite the street railway powerhouse, Montreal. With the two furnaces set up they are able to turn out four tons of babbitt metal per day. Finding that they cannot fill their orders on stereo, electro and linotype metal as well as solder they are now preparing to build one more furnace for making babbitt metal and one for solder and other metals. They have laid in a large stock of raw material, such as pig tin, pig lead, antimony, ingot copper, ingot brass, as well as scrap copper, scrap brass, aluminium and numerous other metals, so as to be able to supply all customers with everything in the line of metal that they may require. The business will continue to increase on account of the quality and price of the metals supplied by this company.

THE AMERICAN STOKER COMPANY.

We have been requested by the American Stoker Co. to publish the following letter:

Montreal, June 29, 1898.

The General Engineering Company of Ontario, Limited,
80 Canada Life Building,
Toronto, Ont.

Dear Sirs:—The American Stoker Company, having an office at room 54, Street Railway Chambers, Montreal, have submitted to us your circular letter, dated 26th of May, 1898, in which it is stated that the American Stoker now being introduced into Canada by the American Stoker Company, is an infringement on certain alleged Canadian patents owned by you, and that as soon as the American stoker is installed in Canada, your solicitors have been instructed to take proceedings in the Exchequer Court of Canada against the user as well as against the manufacturer and importer, and warning the public against the use of the American stoker. We are instructed by the American Stoker Company to inform you that the stokers manufactured by our clients are protected by Canadian patents and are not an infringement of any patents legally held by your company.

We are also instructed to inform you that the American stoker company have sold and delivered five stokers to the Dominion Cotton Mills Company, and are about making delivery of stokers to other purchasers in Canada, and are prepared to defend any action for infringement or damages which may be brought by your company in virtue of such sales for the use which may be made by the purchasers of these stokers, and we are authorized to accept service of any legal proceedings which you may bring against the American Stoker Company.

We have further to inform you that in the event of your Company not making good your threats contained in your

circular letter within fourteen days from this date, which are calculated to deter prospective users of the stokers from purchasing from our clients, we are instructed by the American Stoker Company to institute legal proceedings against you for damages, and for an injunction to restrain you from threatening legal proceedings on the ground of alleged infringement of patents. All other rights are reserved.

Your obedient servants,

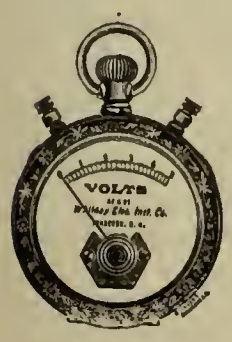
MACMASTER & MACLENNAN.

FIRES OF THE MONTH.

June 1st—The Union Abattoir Co.'s buildings, St. Henri, Montreal; loss about $150,000.——June 4th—Dixon & Gibbon's spice mill, Winnipeg; machinery destroyed.——June 4th—D. LaLiberte's foundry and machine shop, St. John's, Que.; loss about $3,000.——June 5th—S. R. Foster's pottery, Hamilton, Ont.; loss about $4,000; insurance, $2,700.——June 5th—A. Smith's stove mill, Fesserton, Ont., detroyed.——June 10th.—Jos. Bourque's planing mill, Hull, Que.; loss about $8,000. ——June 13th—Acton, Ont., Tanning Co.'s premises damaged to the extent of $500.——June 14th—John McCleary's saw mill, Bristol Ridge, Que.; total loss.——June 14th—Burley & Galligan's foundry and machine shop, Rat Portage, Ont.; loss, $25,000.——June 15th—The Sherbrooke Yarn Mills and C. E. Shedrick's, electrical instrument maker, Sherbrooke, Que; loss partially covered by insurance. C. F. Shedrick's business was continued at once.——June 18th—R. Arnott's cheese box factory, Peterborough, Ont.; destroyed; insurance, small.——June 19th—Oxbow, N. W. T., Milling Co.'s flour mills; no insurance.——June 19th—R. Sloate's saw mill, Tracey's Mills, N. B.; loss, $8,000.——June 21st—The Coleman Lumber Co.'s planing mill, Burlington, Ont.; loss about $10,000——June 23rd—Buck's Stove Works, Brantford, Ont.; pattern shop destroyed.——June 23rd—A. McDonald's saw mill, Peterborough, Ont.; insurance, $3,000.——June 24th—W. W. Doherty's saw mill, Campbelltown, N. B.; loss, $10,000; no insurance.——June 26th—Clifton Hotel, Niagara Falls, Ont., $60,000.——June 29—T. Ebbage's planing mill, Acton, Ont.; loss, about $700.——July 2nd—Court house and jail, St. Thomas, Ont.; loss, $50,000.——July 2nd—G. H. Harper & Co.'s flour mill, near Dundas, Ont.; loss, about $20,000.——July 5th—St. Bernard's convent, Antigonish, N. S.; loss, $25,000.

A POCKET VOLTMETER.

The Whitney Electrical Instrument Company, Penacook, N H., is manufacturing a line of pocket voltmeters and milammeters for continous current. They are made in the form of a watch, as will be seen from the accompanying illustration of the voltmeter.



This instrument has a range from zero to five volts, and was designed to meet a demand among battery users for a low reading and convenient voltmeter. The principle of construction is the same as that of the Whitney Company's standard portable voltmeters for direct current, and the instrument is built with the same care. It is accurately calibrated, and the scale is drawn in by hand. The works are mounted in a handsome silveroid case, which will remain bright indefinitely, and is about the same size as a gentleman's watch. With this pocket voltmeter, the operator of an electric vehicle, or the engineer of an electric launch, can quickly determine which of his accumulators are "dead" and cut them out, thereby getting the full benefit of the good cells.

☞ These instruments are being manufactured in Sherbrooke, Que., by C. E. Shedrick, whose catalogue also contains a large number of other interesting features.

STEAM VS. ELECTRICITY.

The report of James Milne, the expert employed by Toronto to make a report on the cost of an electric power supply for street lighting and commercial purposes has been made. Mr. Milne reports that the data received from the users of both electric and steam power is not to be absolutely relied on for the purposes of careful calculations, owing to the different bases upon which the various returns have been prepared. The summary of the steam users shows a consumption of 16,802 horse-power, from which 10,000 may be deducted for the Toronto Railway Company, Toronto Electric Light Company, Incandescent Light and Corporation plants, leaving 6,802 horse-power for commercial purposes. Of this amount he says, nearly 1,000 horse-power could be supplied by electric power or gas as cheaply as at present, but for the remaining 5,800 horse-power it is useless trying to persuade the manufacturers to change from their present methods, because some profess themselves well satisfied with the steam plants already installed; some use refuse for fuel, some require steam for heating, drying, etc., and others wish the source of their power to be independent. Mr. Milne also stated that in many businesses the cost of power was a very inconsiderable part of the expense of production, and the saving to be made by using electricity not sufficient to make the change desirable.

Railway Matters.

Truro, N.S., has voted a bonus of $30,000 to the Midland Railway.

The C.P.R. authorities have increased wages all around about ten per cent. to the trainmen in the Ottawa and Quebec division.

The Grand Trunk Railway has ordered ten hundred and fifty double-deck stock cars from the Michigan Peninsular Car Company.

The city of Brantford, Ont., is asking the G.T.R. to spend $7,000 in extending the bridge in connection with the proposed flood-prevention works.

The C.P.R. is making a large addition to the rolling stock at the Perth, Ont., workshops. There are 250 flat cars, 200 box cars, and 50 coal cars now in the course of construction there for use generally over the road.

The surveys have been completed on the Nelson and Bedlington Railway, which will give West Kootenay's mining centre of Nelson, B.C., direct communication with the United States, via Bedlington, a point near the Idaho boundary of British Columbia.

There are four parties in the field working the surveys for the new C.P.R. line north from Toronto. H. D. Lumsden is chief engineer, and the chiefs of the parties are Messrs. Brunel, Mitchell, Morris and C. B. Smith, whose districts are respectively French River to Sudbury, French River to Parry Sound, Parry Sound to Severn River, and Severn River to Kleinburg.

The C.P.R. is willing to spend $75,000 on yards and shops at Calgary, N.W.T., but object to the conditions which the council sought to attach to the $25,000 bonus. The conditions suggested by the council included the inspection of the company's time sheets and a forfeit if the C.P.R. shops moved from Calgary before 25 years.

The Windsor station of the C.P.R. at Montreal is to be enlarged by the addition, entailing the outlay of a quarter of a million dollars, or possibly more. The extension will be west on Osborne street, and will make the building twice its present size. It will be of the same material and in the same style, and when finished will make one of the most complete railway offices and depots on the continent.

It has been stated that the G.T.R. would shortly commence the construction of a line from a point on the Northern to the Sault. The line will run northwest, crossing the French River in the township of Mowat, and striking the Sault branch of the C.P.R. at Massey. The G.T.R. have running powers over portions of the road from Massey to the Sault. A good deal of grading and rock cutting was done some years ago on the line east of Massey.

The Robson-Penticton Railway has been surveyed to connect with the C. & W. at Robson, thence up the Lower Arrow Lake to Dog Creek; up this stream to McCrea Pass; thence down McCrea Creek and Christine Lake to Cascade City; along Kettle River to Grand Forks; up the north fork and Brown's Creek to Eholt Pass: down Eholt Creek to Boundary Creek, and through Greenwood, Anaconda and Boundary Falls to Midway. The route is 100 miles long and is filled with engineering problems.

The annual meeting of the Quebec Central Railway was held in London, England, on June 6th. It was reported that the gross earnings for the year ending December 31 last, amounted to $457,643, being an increase of $60,537 over those of the preceding year. The working expenses amounted to $309,555, being an increase of $40,761. The net earnings were $148,088, being an increase of $19,776, to which was added interest on balances, etc., $2,830, and there had been written off some items amounting to $2,954, making the available net revenue $147,964. After paying interest on the prior lien bonds, $85,166, there remained a balance of $62,798, out of which a dividend of one and one-half per cent. had been declared and paid on the income bonds, leaving $13,450 to be carried forward. The percentage of the working expenses was 67.64 per cent. as compared with 67.68 per cent. for the previous year.

It has been proposed that the Central Ontario Railway, from Picton to Coehill, be extended into the mining district.

The Alberta Railway and Coal Co. of Lethbridge, N.W.T., has ordered two more Munford Improved Boilers of 150 horse-power each from the Robb Engineering Co., Amherst, N.S.

The St. Hyacinthe and Granby Railway proposes building a bridge across the Yamaska and a passenger depot. The proprietors have petitioned the St. Hyacinthe, Que., council for a grant of $75,000.

The engineers in charge, Lauthier and O'Dwyer, have completed the final location of the Great Northern Railway, between Shawenegan and Montcalm, a distance of 53 miles, which completes the gap between the constructed sections of the railway.

Three hundred men have started work grading the right of way for the proposed railway from Skaguay to the lakes. The work is being done by the Pacific and Arctic R. & N. Co., of West Virginia, which is said to have secured the charter and holdings of the British Yukon Company.

The track-laying on the Ottawa and Montreal road, the new C P.R. short line, has been completed. All that now remains is to make the connection with the Canada Atlantic Railway tracks and complete the ballasting. Some 250 carloads are being deposited on the line every day. The bridge across the Rideau is completed and is being painted. All the stations along the line are ready for occupation.

Electric Flashes.

The town of Thorold will borrow $7 000 to extend the municipal lighting plant.

The Great Northwestern Telegraph Company has completed an extension of their line into British Columbia.

The Little Salmon River Telephone Company applies for an extension of its charter powers and it will then extend its lines.

E. I. Sifton has been appointed manager of the Electrical Construction Co., London, Ont., in place of S. R Break, who has gone to Arizona.

John R. Coffman, who for the past year has filled the position of superintendent for the London Electrical Construction Co., has returned to Detroit.

The Toronto Railway Company has placed an additional order for ten C G.E. 1,000 two motor equipments with the Canadian General Electric Company.

The Montreal Street Railway Company has erected a new brick blacksmith shop at Hochelaga, 75 by 58 feet; the building is also to be used for the company's repairing work.

The town of Acton, Ont., is contemplating the installation of a municipal electric lighting plant. The estimates were supplied to the council by Mr. R. J. Parke, consulting electrical engineer.

The Wm. Cane & Sons Mfg. Co., Ltd., of Newmarket, has placed an order with the Canadian General Electric Company for a 17½ kilowatt four-pole lighting generator and marble switchboard.

Ladies ran the street cars of Cornwall, Ont., on the 15th of June, and a percentage of the earnings of the road on that day, which were large, were given to the General Hospital and Hotel Dieu.

C. E. Shedrick, manufacturer of electrical measuring instruments, Sherbrooke, Que., suffered considerable damage from smoke and water when the Sherbrooke Yarn Mills were burnt down, June 15th.

R. Prefontaine, Ste. Agathe des Monts, Qne., has placed an order with the Canadian General Electric Company for a one thousand-light single phase standard ironclad armature type of alternating current generator.

The town of Listowel, Ont , is considering a by-law impowering the municipality to borrow $19,700 for waterworks and electric lighting. The plans and estimates for the work were prepared by John Galt, C.E , Toronto.

The Quebec electric railways and the Quebec, Montmorency and Charlevoix railways have been amalgamated and will have a working capital of $3,000,000. It is stated that the company will buy the Montmorency Falls outright.

The Shawenegan Water and Power Co., which has been incorporated to develope and utilize the water power at Shawenegan, Que., will not manufacture pulp at present, it has been decided, confining itself to the production of power. The incorporators of the company are David Russell, Montreal; John Joyce, Boston; William Strachan, Montreal, and others. Thos. Pringle, Montreal, has the work of development in hand.

The Berlin, Ont., Electric Light Co. has bought a 165-h p. boiler from a London, Ont., firm.

The Hamilton Electric Light and Power Company, Ltd., has placed an order with the Canadian General Electric Company for a 200-kilowatt 250-volt generator which they intend using on their power circuit.

The flow of the river Credit was recently measured by parties interested in electrical development in Toronto. It is hardly probable that the volume of water will be found sufficient to produce any very considerable power.

During May the Galt, Preston and Hespeler Street Railway handled 950 tons of freight, a slight increase over the corresponding month of last year, and carried 18,000 passengers, an increase of about 500 over May, 1897.

The first electric car traversed St. Thomas' streets June 15th. The electric street railway begun March 24 has been completed, and was opened for public travel on the 16th. The road is six miles in length and cost $80,000. The formal opening was held July 5th.

The Cornwall, Ont., Electric Street Railway Company, Ltd., in consequence of the increased demands on the freight service, has ordered another freight locomotive and has placed an order with the Canadian General Electric Company for the electrical equipment, consisting of four C.G.E. 1,200 motors.

The Pembroke Navigation Company has placed an order with the Canadian General Electric Company for equipping the steamer "Victoria" with a complete electric lighting plant, which will include a six-kilowatt standard Edison type dynamo, a vertical automatic engine and a search lamp of 4,000 candle power.

Judge McDougall has handed out judgment granting the motion to quash the indictment preferred at the December Sessions, 1897, against the Toronto and Mimico Railway Company, charging the latter with running their cars on Sunday, contrary to 60 Victoria, cap. 14 sec. 95, and sec. 138 of the Criminal Code. This allows the line to run Sunday cars.

The Canadian Pacific Railway, which has recently acquired the smelter at Trail, B.C., formerly operated by Aug. Heinze, has concluded negotiations with the West Kootenay Power and Light Co. for the supply of electric current to operate the smelter, and have ordered from the Canadian General Electric Co. two 75 k.w. three-phase revolving armature type synchronous motors, which will be operated at a potential of 550 volts. They have also ordered three 50-h.p. induction motors and three 30-h.p. induction motors which will also be operated at a potential of 550 volts.

The Lang Tanning Co., Berlin, Ont., has recently given an order to the Canadian General Electric Co. for a 100-k.w. multipolar direct current dynamo, which will be operated at a potential of 250 volts. This generator will supply current for the operation of two of the Canadian General Electric Co.'s latest type of multipolar direct current motors, each having a capacity of 50-h.p. and one 10-h.p. motor. The order given to the General Electric Co. also includes the installation of a marble panel switchboard, containing the necessary instruments for the operation of the plant and the wiring up of their factory.

A. E. Carr, superintendent of the London, Ont., Street Railway Company, has been appointed superintendent of the Montreal Park and Island Railway, in succession to A. J. Corriveau, who recently resigned. Mr. Carr still retains his position with the London company, and will, it is said, manage both jointly. When only sixteen Mr. Carr was secretary-treasurer of the sewer department at the Toronto city hall, and had after that experience as private secretary to H. A. Everett, formerly of the Toronto Railway Company. He was appointed to his present position in London in 1895.

The Carborundum Company, of Niagara Falls, has commenced the manufacture of its product in Canada under the patent which it holds. It has just built a new factory building at Niagara Falls, Ont., but the electrical apparatus not having arrived in time for the plant to be utilized in accordance with the patent provisions, in order to maintain its rights, the company, with considerable enterprise, erected a furnace in the power house of the Niagara Falls Park and River Railway Company and there made the first carborundum produced in the Dominion. Carborundum has been increasing in popularity, and the output on the New York side of Niagara has been materially increased. Now the company is erecting a three story brick building, 50 x 228 at the foundation, in which they will spread carborundum on cloth and paper, thus bringing carborundum in competition with the flint, garnet and other paper manufactures in the United States, of which, it is said, there are seven or eight. This new branch of the company's business is expected to reach large proportions, and it is expected that it will make necessary a still further increase of the carborundum producing plant. The president of the company is E. G. Acheson.

The Lakeport Preserving Co. has given an order for the installation of a lighting plant for its factory to the Canadian General Electric Co.

The Electric Co. of St. Johns, Nfld., is increasing its plant and has ordered a 150-h.p. tandem compound engine from the Robb Engineering Co., Amherst, N.S.

For the rebuilding of the retaining walls of its railway the Hamilton and Barton Incline Company has awarded the contract to Rowan & Elliott, of St. Catharines, Ont.

The Toronto Railway Co., which recently ordered a number of the Canadian General Electric Co.'s well-known type of C.G.E. 1,000-motors, has given an order for additional equipments.

The Strathroy, Ont., Electric Co., Ltd., has met with so much success that it has recently placed an order with the Canadian General Electric Co. for the installation of another 500-light single-phase alternator.

The Toronto Electric Light Co. has been ordered by the city council to extend its system to the Island at 20½ cents per light, as the Island is part of the city and the company's charter covers the whole city.

The R. Forbes Co., Ltd., Hespeler, Ont., has placed an order with the Canadian General Electric Co. for two 500-light Generators. These generators are to be supplied of the Canadian General Electric Co.'s latest four-pole type.

Hon. John Haggart, Perth, and others, have been incorporated under the name of "The Canadian Electric and Water Power Company," with a capital stock of $150,000, to produce and distribute electricity in Perth, as well as in other towns in Canada.

La Compagnie Manufacturiers et Electrique de Montmagny has given an order to the Canadian General Electric Co. for a 100-k.w. monocyclic generator, which will be operated at a potential of 2,080 volts, together with the necessary station instruments for the operation of the plant.

The West Kootenay Power and Light Co., who have just closed a contract with the C.P.R. authorities for the supply of electric current to operate their Trail smelter, have placed an order with the Canadian General Electric Co. for the supply of three 135-k.w. transformers of the well-known air blast sub-station type.

The Lachine Rapids Hydraulic and Land Co., of Montreal, has given an order to the Canadian General Electric Co. for the installation of a seven-panel power-house switchboard, which is to be built in accordance with specifications and drawings prepared by R R. Kelsch, superintendent for the Lachine Rapids Hydraulic and Land Co.

The citizens of Hamilton will vote on July 27th to decide the following questions about the street railway: 1. Shall the city purchase and operate the Hamilton Street Railway? 2. If the city does not now purchase the Hamilton Street Railway, should the council extend the franchise of the company for fifteen years, that is until 1928?

The town of Granby, Que., recently gave the contract for the installation of its lighting plant to the Canadian General Electric Co. This plant will consist of a 100 k.w. monocyclic generator, complete equipment of station instruments and a 50-light "Wood" arc dynamo. The contract also includes the complete installation of the pole line, transformers and house wiring required.

The city of New Westminster is resisting the proposal of a company, of which F. S. Barnard is a director, to tap the waters of Coquitlam Lake, with a view to electric power. The city authorities believe that New Westminster will need all the water it can get for public uses from the lake, over which it has, under Act of the legislature, rights of user as a city reservoir.

The Hudson Bay Co. has given an order to the Canadian General Electric Co. for the installation of a complete lighting plant for its stores at Calgary, N.W.T. The plant will consist of one of the Canadian General Electric Co.'s latest four-pole type generators, having a capacity of 9 kilowatts. The Goldie & McCulloch Co., Ltd., Galt, Ont., is supplying the engine and boiler required for this installation.

The works of the Ottawa Carbon and Porcelain Company are very busy at the present time. This is the only factory in Canada for the production of electrical porcelain and carbon goods, and ever since its establishment in the capital city it has made steady progress. At first the carbons produced were in some cases not up to the mark, but great improvements have been made in the process of manufacturing, and the carbons turned out this year by the company are equal to any imported goods. Besides the carbon goods for electric light purposes, the company manufacture motor brushes, and specialties in carbon for telegraph and telephone work as well. The porcelain goods include door knobs and other goods used in the hardware trade, as well as porcelain insulators, etc.

The Electric and Operating Co., Brantford, Ont., will spend $10,000 in enlarging its plant in consequence of the civic lighting contract recently entered into.

The Electric Co., St Johns, Nfld., is increasing its plant and have ordered a 150 horse-power Tandem compound engine from the Robb Engineering Co., Amherst, N.S

The Niagara Falls Park and River Railway Company ran their first trolley over the arch bridge July 1st. Mr. Rothery, superintendent of the road, was at the motor; Manager Phillips and Bridge Superintendent Dill, together with a number of other prominent citizens, were inside.

Personal.

J. R. Joughins has been appointed master mechanic of the Intercolonial Railway.

T. C. Keefer, C.E., Ottawa, was elected president of the Royal Society of Canada at its last meeting.

John Kelman, formerly of Galt, Ont, is superintendent of the Stanley Electric Mfg. Co, Pittsfield, Mass.

Thomas Graham, of the Banner File Works, Almonte, Ont., has recovered from his recent very severe illness.

J. Walter Wells, of the Kingston School of Mines, has been appointed to take charge of the assay office at Belleville, Ont.

Jas. Devlin, formerly chief engineer Kingston Penitentiary, is now one of the proprietors of the Albion Hotel, McGill st., Montreal.

C. J. Crowley, Toronto, resident engineer for the Midland Division of the Grand Trunk, severed his connection with the road on June 1.

A. P. Rankin, marine architect and engineer, formerly of Toronto, is now engaged at the works of the Cleveland Shipbuilding Co., Cleveland, Ohio.

T. W. Hugo, formerly of Kingston, Ont., is now consulting engineer for the elevator system in Duluth, Min., as well as for the electrical railway system.

A. K. Spotton, for some time draughtsman with the Waterous Engine Co., Brantford, Ont., has secured a similar position with a Toronto firm.

John O'Brien, formerly miller for Gould Bros., Uxbridge, Ont., was so badly injured by mill machinery at Creemore a short time ago that he died.

Yorke Kirton, who has been in the employ of the Lancaster Machine Works for the past five years, has gone to the works of John Bertram & Sons, Dundas, Ont.

James Stephenson, ex-general superintendent of the Grand Trunk, has, with Mrs. Stephenson, taken up his residence in a pleasant villa in the town of Cheltenham, England.

Dr. Bowen, who has been president of the Thousand Island Carriage Co. since the manufactory started, has resigned his position, and will resume the practice of medicine in Gananoque, Ont.

Henry Penton, formerly of Sarnia, Ont., now holds the position of superintendent of the engineering department of the Chicago Shipbuilding Company, one of the largest institutions of its class on the great lakes.

Wm. Mailing, the Rat Portage, Ont., agent of the Ottawa Powder Company, met with a serious accident recently which will deprive him of the use of one of his eyes. It appears that Mr. Mailing was testing a new electric battery with a percussion cap, when the premature explosion occurred, with the result that the full force of the cap expended itself in the neighborhood of his eyes.

J. H. C. Haldane, C.E., of Liverpool, England, has been travelling in Canada lately with a view of getting up a volume describing the country from the point of view of its engineering possibilities. Mr. Haldane has already published a number of books, among which are "Civil and Mechanical Engineering Popularly Considered," and "Steamships and their Machines from First to Last."

George A. Macagy, for the past three years superintendent for the hardware firm of Peck, Benny & Co., Montreal, died recently in Montreal very suddenly. Mr. Macagy had enjoyed uniform good health during the forty-seven years of his life. However, he complained of a slight indisposition, and died before medical aid could be summoned. He was born in Halifax, N.S., in 1851. Moving to Toronto while quite a young man, he entered the hardware firm of Rice Lewis & Sons, of that city, with whom he remained for seven years. He then came to Montreal, and was for seven years secretary of the Pillow-Hersey Company. Three years ago he became superintendent for Peck, Benny & Co.

W. M. Cathels, for twenty years secretary and manager of the Gas Light Co., Fredricton, N.B., has resigned his position to accept a situation in Brantford, Ont.

William Young, who has been for a number of years chief engineer on one of the Pacific mail steamers running between San Francisco and Panama, has retired from active service and returned to his home in Galt, Ont.

Michael Kelly, who died recently in Montreal, will be lamented by a large number of friends. Mr. Kelly had been recently appointed inspector of timber for the port and district of Montreal. In Quebec, Mr. Kelly was recognized as the best inspector of timber in the country, and when the timber trade largely moved to Montreal he was transferred there by Hon. John Costigan.

Ephrem Valiquette, president of the Ingeneurs-Mecaniciens Association Canadienne de Secours Mutuels, who was the winner of the gold medal at the Industrial and Mechanical Course at the Monument National, is the son of a farmer, born on June 18, 1865, at St. Martin, Laval county, Que. He is provincial boiler inspector, and also a member of the Canadian Association of Stationary Engineers. Mr. Valiquette, who has recently left the employ of W. Rutherford & Sons, was presented on that occasion with a handsome silver water jug, as a token of respect, on his leaving their employ, to become foreman for Lymburner & Mathews, mechanical engineers, of Montreal, where he is now employed.

D. W. Crockett, who died a short time ago at Hopewell, N.S., was widely known throughout the province, and particularly in Eastern Nova Scotia, where in former years he had extensive business relations. For many years he had been a government surveyor and was closely connected with the development of gold mining in the Goldenville district, having resided in Wine Harbor and other parts of Guysboro county for several years. He assisted in the construction of the telegraph line from Halifax to Guysboro and was connected with several other important enterprises in Guysboro county. He was one of the chief promoters of the Hopewell Woolen Mill Co., Ltd., of which he was secretary and manager until the property was destroyed by fire ten or twelve years ago. Chas. M. Crockett, a partner in the engineering firm of I. Matheson & Co., New Glasgow, N.S., is a son of the deceased.

Marine News.

The Yarmouth, N. S., Steamship Co., has placed the new steamer "Express" on the South Coast service.

The steamer channel running to the wharf at Depot harbor, Parry Sound, has a depth of 30 feet at the shallowest points.

The contract for the iron work of the hydraulic lift lock in Ashburnham, Ont., has been awarded to the Dominion Bridge Works, of Montreal, they being the lowest tenderers.

The contract for transporting the yearly supplies to the Government light-houses in inland waters has been let to the steamer "Seguin," owned by J. B. Miller, of Parry Sound.

Captain Pratt, Cheverie, N. S., is going to place a steamer on the route between that place, Windsor and St. John. The engines are being built at Yarmouth by the Burrell Johnson Iron Company.

The new steamer of Boutilier and Moorehouse, Centreville, Digby County, N. S., is at the works of the Burrell Johnson Iron Company, Yarmouth, N. S., having her engines and boiler placed on board.

The contract for the iron work of the hydraulic lift lock in Ashburnham has been awarded to the Dominion Bridge Works, of Montreal, they being the lowest tenderers. This is one of the largest contracts, in a single structure in iron work, that has ever been let in Canada.

The Davis Dry Dock Co., Kingston, Ont., is rebuilding at a cost of $5,000 the C. P. R. car-ferry steamer "International," which runs between Prescott, Ont., and Ogdensburg, N. Y. The same firm has a 35-foot steam yacht nearly completed, which has been built for the Muskoka lakes to the order of S. E. Gill, Steubenville, Ohio.

The steamer "Lynne," which made its maiden trip to Depot Harbor, Parry Sound, with a cargo of 214,500 bushels of corn on a draft of 19 feet, served to show what we may expect from the future development of this great port.

James Finney, of St. Thomas, has been awarded the contract for building a bridge over the Otter Creek between Elgin and Oxford.

Bras d'Or Steamboat Company, Limited, has applied for a Nova Scotia charter to carry on a general ship-owning business; capital, $20,000.

A new contract will be necessary for the reconstruction of the breakwater and repairs to piers at Goderich, Ont. The contract was originally awarded to Luke Madigan at $50,099, but he was unable to carry out the work

The Beaver Line steamer "Lake Winnipeg" is to be replaced by the New Zealand Royal Mail Shipping Co.'s steamship "Tongariro. This vessel, which has a speed of 14 knots, can accommodate 120 saloon, 70 second cabin and 250 steerage passengers.

J. D. Reid, M. D., Cardinal, Ont.; G. F. Benson, Montreal, P. Q.; D. Gow, M. D., Cardinal, Ont.; G Hall, Ogdensburg, N. Y.; J. K. Dowsley, Prescott, Ont., have applied for incorporation as The Prescott and Lake Superior Navigation Company, Limited; capital, $100,000.

The "Eurydice," the property of Sylvester Bros, Toronto, has been sold to Campbell & Rosenecke, of Buffalo, for about $6,000. The "Eurydice" has been the subject of considerable liquidation recently. Last summer she was sold to parties at Port Stanley, the price agreed upon being $10,000. The purchasers afterwards refused to receive the boat, however, and took action against the owners. The new purchasers, it is understood, will run the "Eurydice" between Buffalo and Chippewa as an excursion steamer.

J. R. Roy, resident engineer of the Dominion Government in British Columbia, who was sent up with J. L. N. Coste, the chief engineer of the Public Works Department, to examine the all-Canadian route to the Yukon, has returned to Victoria, and reports the Stickine to be a fine body of water, which steamers drawing not more than thirty or forty inches, and having powerful enough engines, may navigate for six months in the year. The trouble this season has been, he says, that several steamers with engines not powerful enough have attempted to ascend the river. The Government boat "Samson," sent to remove obstructions, could only ascend seventy-five miles.

The following have been examined by W. L. Waring, St. John, N. B., examiner of marine engineers, and passed for the following grades: O. T. Berry, St. John, third class engineers' certificate; Wm. Atkinson, Fredericton, third class engineers' certificate; G. G. Miller, Chatham, third class engineers' certificate; E. H. Haviland, Chatham, third class engineers' certificate; W. W. McLaren, Georgetown, P. E. Island, fourth class engineers' certificate; R. A. McHarg, St. John, fourth class certificate; R. S. Pendleton, Deer Island, permit; H. V. Pye, Hopewell Cape, permit; F. W. Richardson, Deer Island, permit; E. H. Strang, Lansdowne, P. E. Island, permit.

The Summer School of the Massachusetts Institute of Technology in Civil Engineering will be held at Lancaster, Mass., this year. This course in geodesy, topography and hydraulics is open to third-year men in the Civil Engineering Department. It is expected that twenty-four men, including six instructors, will attend. The work will cover, among other things, the gauging of the Nashua River below the dam, the use of the meter on the mill flumes at Clinton, the rating of the meters on Spectacle Pond, and the production of a topographical map of the vicinity of Lancaster, based on the State triangulation. Lancaster offers exceptional opportunities, not only for the work above mentioned, but also for the observation and study of the new Metropolitan Dam now being constructed, and the preparation of the basin by stripping and cleaning.

The Manchester-Canadian service is to be augmented by a new screw steamer, which has been built by Sir Raylton Dixon & Co., Middlesborough, Eng., for the Manchester Liners, Limited. Her principal dimensions are: Length over all, 461 feet; length between perpendiculars, 445 feet; breadth, 52 feet; depth moulded to upper deck, 33 feet, and to shelter deck, 40 feet 9 inches; upper bridge upon shelter deck, 128 feet long; height of upper 'tween decks, 7 feet 9 inches; height between upper and main decks, 9 feet 6 inches. The engines will indicate 4,000 h.p. and give 13 knots. The boilers, four in number, are fitted up with Howden's system of forced draught. The ship's deadweight capacity is 8,500 tons on a draught of 26 feet 3 inches, and her measurement capacity, including bunkers, about 13,000

tons. The permanent bunkers have a capacity of 1,052 tons. The "Manchester City" is expected to be ready for sea in about six weeks, and after undergoing her steam trials she will take up the regular service between Manchester and Montreal.

Mining Matters.

W. A. Saunders is to put in another steam pump at the Golden Lode mine at South Uniacke.

A number of productive oil wells have recently been sunk in Lambton county, at Inwood, Ont.

The Calumet, Que., Mining Co., has made another rich discovery on the Upper Ottawa. It is a new mine in which is said to be nearly 40 per cent of silver.

A Wilfley concentrator is being put in by the Truro Foundry Co., at the Richardson mine at Isaacs Harbor, which will be tried on two batteries as a test.

The Bureau of Mines received a letter from Michipicoten, giving the assay of sand in the placer regions of $1.50 to $6 per ton, in gold. A ton of the sand has been shipped to the Toronto Mining School for experimenting.

The Hillsboro, N. B., manganese works, which have been temporarily closed down for two weeks on account of an accident to the machinery, have resumed operations again. The repairs to the manganese press have been made by J. Weir & Sons, Moncton.

The largest flow of oil since the Petrolea oil discovery was struck last month by Trotter and McHugh of Chatham, while boring on the Herbert farm, situated about two miles from Thamesville, Ont., in the Township of Zone. It is one of a number of wells that have been lately put down in the vicinity of Thamesville. The well when tested yielded 40 barrels per hour.

On June 18 a fire and an explosion occurred in the hoisting and compressor house of the Asbestos & Asbestic Company's works near Danville, Que. Two men were instantly killed, and one other man so badly injured that he died shortly after. The loss to the company's property is heavy, and the detention of operations will be serious, as a number of large orders were being filled. The exact cause of the explosion cannot be ascertained, though it took place by the ignition of dualine.

We observe the application for incorporation of the Eastern Townships Chrome Iron Mining and Milling Company (Limited), capital stock of $50,000, headquarters Montreal; to produce and mill gold, silver, copper, chrome iron, etc.; the parties being R. Prefontaine, M.P., J. R. Fair, Montreal; C. A. Chenevert, M.P.P., Berthierville; J. U. Gregory, Quebec; C. [illegible]ing, Sherbrooke, etc.

The Bureau of Mines has issued a map of the corundum belt in Eastern Ontario, and is sending out a number of circulars, containing in concise form information concerning these deposits. The corundum bearing lands have an aggregate area of 50,000 acres. The mineral rights over nearly the whole of this tract are held by the Crown, and they have been withdrawn from sale and lease pending a report on the occurrence of the mineral and the methods of treating it, undertaken by the professors of the Kingston School of Mining. This report and a map of the region will be issued shortly.

Prof. De Kolb, of the School of Mines, Kingston, has been appointed inspector of mines for Ontario by the Local Government, in place of the Rev. A. Slaght, who died a few days ago. This office is in addition to the professor's present position, as he can perform the duties during the vacation season.

A. P. Lowe, of the Geological Survey staff, Ottawa, has left for eighteen months' field work in the interior of Labrador, continuing the line which he has been engaged upon for some seasons. It has been said that gold exists in Labrador in paying quantities, and an abundance of iron and of coal in different localities.

The first general meeting of the recently incorporated Canadian Mining Institute was held in the Windsor Hotel, Montreal, June 3rd, the president, John E. Hardman, in the chair. The principal business was the establishing of headquarters, with a mining library, in Montreal. The library, which will be located in room 4, Windsor Hotel, will be stocked with books, of which the institute already possesses about 500 volumes, periodicals, papers, maps, etc., relative to mining matters. These will be at the service of those desiring to obtain information relative to the Dominion's mining resources. Reliable information will thus be disseminated. The Dominion Government has made a grant to it of $1,000. A library committee was appointed, consisting of G. E. Drummond, convener; J. Stevenson Brown, H. B. de Courtenay, the president, and B. T. A. Bell, secretary.

—THE CANADIAN ENGINEER continues as interesting as ever to all engaged in metal, electrical, or mining work. It is monthly, only $1 a year, issued by Biggar, Samuel & Co., Fraser Building, Montreal, and should be in the hands of all mechanics.—Truro, N.S., Daily News.

—The members of the Toronto Astronomical and Physical Society Toronto, had an address delivered before them on "Our Atmospheric Ocean," by F. Napier Denison, June 28th. The lecturer gave the causes of air currents, dealing with special features of cyclones. He pointed out the various effects of aerial movement upon lakes and oceans, illustrating his statements by producing weather charts. The stereopticon views all through the lecture added much to its interest. Mr. Denison leaves Toronto almost immediately for British Columbia, where he will take charge of the weather forecasting department of the Observatory.

—Under the authorization of an act of the New York Legislature, that state will establish a College of Forestry. A conference has already been held at Albany to decide upon the location of 30,000 acres of land to be purchased for the purpose. No particular plot of ground has as yet been definitely picked upon. The conditions which the authorities decided upon as necessary in seeking land for the new college were formulated by Dr. Fernow, formerly chief of the forestry division of the department of agriculture at Washington, now director of the new State College of Forestry at Cornell University.—From the Railway Review.

—The results of the tests of the Roebling system of fireproof construction, in which a concrete arch, strengthened with steel rods, constitutes the floor support, will, we think, be a surprise to those who have not known hitherto the value of concrete as a fire-resisting material. That an arch of this construction of 4 ft. span, only 3 ins. thick in the centre, could support a floor loaded with 150 lbs. per sq. ft., while a fire was kept under it for five hours, reaching a temperature of above 2,300 deg. F., or beyond the melting point of copper and even of cast-iron, and then after this heating and sudden cooling by a stream of water could withstand a load of 600 lbs. without fracture, would, says the Engineering News, be considered highly improbable had it not been proved by these tests. The competitive test between an arch of concrete and one of hollow tile, in which the latter failed, is one of the most important contributions to our knowledge of the ultimate resistance of fireproof floors which has been made for many years. The manufacturers of tile floors will no doubt have something to say in their own behalf in regard to this test, for it was not an official one, but as the matter stands it looks as if the concrete men had shown that in fire-resisting qualities their construction is at least as good as that which has heretofore been accepted as the best standard construction.

—The total supply of manganese ore for the last year, for which returns are available, was 408,079 tons, and of this we in Britain used some 128,000 tons. The quantity required has been steadily increasing, being now five times what it was ten years ago. This is in part due to its more extended use in high-speed engines, where weight is more important than first cost, and where, therefore, it is preferred for its high tensile strength. It is also more largely adopted now for warships, which are wood and copper sheathed, and therefore require manganese bronze, or some other metal which will not readily corrode. The percentage of manganese is in such cases very small, usually 2 per cent. to 8S per cent. of copper and 10 per cent. of tin in engine castings. Stem and stern frames run up to 15 and 25 tons respectively, while propellers often weigh 17 tons. But withal, the extensive use is somewhat surprising, for what is known as naval brass is more in

favor. The proportions for engine parts are 62 per cent. of copper, 37 per cent. of zinc, and 1 per cent. of tin. While slightly cheaper, it is, as a rule, more uniformly reliable, and the tensile strength of rods is nearly as high, usually 26 tons to 28 tons per square inch. Still, we use 128,000 tons of the ore, and pay for it the very substantial price of three guineas a ton. The metal itself costs from £80 to £100 per ton, so that only great advantage would justify its use. We have to import this ore, our native production being now under 2,000 tons, although some years ago it was 12,000 tons. That, however, was at a time when copper was dear, owing to syndicate manipulations, and then even manganese ore brought nearly £4 per ton. One-half of our supply comes from Russia, a fourth from Chili, and a considerable proportion of the remainder from France. Of the world's supply of 408,079 tons, Russia provides 240,181 tons, mined in the Ural and Southern districts, but principally in the Caucasus. Ten years ago the output was only a tenth what it now is, and the increment has been steady. Germany occupies second place, with a total of 41,854 tons, taken from the Wiesbaden and Coblentz districts close by the Rhine. The production has increased fivefold in 10 years, yet the value is only double. The price per ton has indeed declined in four years or so from about £5 to about £2 per ton. Chili comes third, due to the output of Coquimbio and Atacama, the ores from which give 50 per cent. of manganese, and for it we pay nearly £4 a ton. Their total output is about 40,000 tons, of which we take three-fourths. France has 11 mines, close to the borders of Spain, and the total has increased to 32,239 tons, but is of a low grade, the value being 30s. a ton. Japan, that land of great resource and energy, takes fifth place, and the ore is of high grade. In five years their production has increased from 945 to 13,945 tons. The United States produce 9,547 tons, got principally in Virginia, Georgia, and Arkansas states. Greece has rather decreased her proportion, the total being 9,172 tons. Turkey mined 9,000 tons, while on the borders of Austria-Hungary and Bosnia, there are deposits whence the former get 2,743 and the latter 6,484 tons. Portugal finds 6,848 tons of the world's annual supply, Spain 7,684, Sweden, 3,269, and Colombia 3,950 tons. New South Wales, New Zealand, Queensland and Canada have commenced the mining of manganese ore, and it is to be hoped the colonial supply will increase.

LITERARY NOTES.

We have received from the Association of Civil Engineers of Cornell University the volume of their transactions for 1898. The transactions make a volume of about 200 pages, illustrated by a number of interesting engravings and diagrams. Among the articles of very special importance are those on towns' water supply by E. Kuichling, C.E., and European practice in the disposal of the waste of large cities, by J. H. Furtes, Mem. Am. Soc. C.E.; the present and future prospects of gas for lighting, heating and power purposes, by Henry R. Lordly, C.E.

In 1894 there was published in New York a Canadian novel which Current Literature termed the greatest American book of the year. The New York Herald, Times and other papers paid great attention to it. The title was "The Untempered Wind," and the author Joanna E. Wood. This novel is now published for the first time in Canada by the Ontario Publishing Co. of Toronto, which house also issued in the early part of the year Miss Wood's subsequent novel "Judith Moore." Paper, 50 cents.

The Hunt cable railways for handling coal and merchandise are described in a profusely illustrated catalogue, No. 9,803, recently issued by the C. W. Hunt Co., 45 Broadway, N.Y. Among the plants of which pictures are given is the locomotive coaling plant of C.P.R. at Jackfish Bay on Lake Superior. Catalogue No. 9,806 from the same firm gives details of the automatic railways and coal elevators erected by this firm.

George H. Dobson, of North Sydney, C.B., has written a pamphlet, entitled Ocean Routes and Modern Transportation, which is worthy of consideration by the Dominion Government. Mr. Dobson argues that if Canada's ocean transport facilities had been equal to those of the United States during the past sixty years, this country would have secured a large proportion of the emigrants who went to the United States.

"The Chemistry of Paints" is a pamphlet describing the process of manufacturing white lead and paints followed in the works of Harrison Bros. & Co., Philadelphia, Penn. This firm is one of the oldest in the United States, having been in business since 1793.

The International Correspondence Schools, Scranton, Pa., has sent out a handsome pamphlet describing the origin of the schools and their present condition. A good deal of space is given to a description of the various publications of the schools which are now being issued in bound volumes.

The Herald, Halifax, N.S., has issued a forty-page pamphlet on the Canadian possibilities in Atlantic freight and passenger carrying, entitled "Ocean Routes and Modern Transportation."

We have received for review the "Pioneers of the Klondyke," which is an account of two years' police service on the Yukon by M. H. E. Haine. The book is handsomely illustrated.

THE STEAM ENGINE.

BY WILLIAM GOLDING.

If an ordinary vertical steam engine be converted into a steam elevator by removing the cross-head and putting in its place a platform which shall be loaded with bricks or other units of weight, and steam be admitted below the piston, the platform with its load will ascend; if, however, the steam be shut off when the platform has ascended one-eighth the length of the cylinder, the platform will cease to ascend. As is well known, the steam which has raised the platform through one-eighth of the desired distance, is capable of much further duty; but as the load is constant, no utilization of the steam can be effected, unless the load, in some manner, be lightened. If one brick be removed, the platform with the remaining part of the load will ascend to a point where the steam and the load again become equal; where it will remain. If another brick be removed and the operation continued, the platform will continue to ascend and convey some part of the load to the top. Now it is very certain that all of the work done after the flow of steam was cut off, was accomplished by the expansion of the original steam. And this gain or economy as usually computed is sixty per cent.; yet not one-half of the theoretical gain can be discovered in any practice, and none whatever when the load is constant.

It is usual in estimating the power of the steam engine to compute the average pressure that has been exerted upon the piston as the thrust; and to assume that this pressure has been transferred to useful work. The fallacy of computing the average pressure is illustrated in the pumping engine and the direct piston-elevator, and in the locomotive, as in all of these applications the load is constant and the initial pressure always in demand. Where the load is elastic as in the screw propeller or paddle wheel, operated by engines especially adapted to such duty, a large percentage of the average pressure on the piston may be computed. But where uniform periphery speed is required, as in a mill, the percentage of average pressure to be computed in estimating the actual power developed will be governed by the percentage of irregularity tolerated in the periphery speed of the rotary parts. In fact, if the periphery of the fly-wheel travels with absolutely perfect uniformity of speed throughout each revolution, the load is practically constant and no economy can result from expansion, no matter what point of the stroke the steam may be cut off. To maintain a uniform periphery speed of the rotary parts, it is necessary that the power be uniformly applied to each division of the circle. To this end it is suggested that the greatest measure of economy will be attained by using a cylinder with permanent cut-off for each expansion, each piston to follow at equal divisions of the circle. As in this practice the full economy of steam expansion with perfect uniformity of periphery speed and against a constant load will be attained.

The subject of the fly-wheel, as a part of the steam engine, is not generally understood; and, perhaps, more failures to give satisfaction by otherwise perfect engines may be traced to the mal-proportion of fly-wheel than to all other causes. The fly-wheel is nothing in itself. It neither produces nor consumes. It can only store power by running faster, and can only part with power by running slower. To illustrate: if a single engine is to be constructed to run a mill, and is intended to cut off one-eighth of the stroke, a very large fly-wheel will be required, in order to preserve uniform periphery speed. In this case, the pressure on the piston will vary twice during each revolution, from initial to terminal, to such an extent, that in order to insure even an approximation to uniform periphery speed, a fly-wheel of unheard of proportion would be required.

The question now arises what becomes of the initial pressure when the fly-wheel is sufficiently heavy to insure perfect rotary motion; surely it cannot be averaged with the diminishing pressure, and counted as thrust, as is the practice (per indicator). For this would necessitate the fly-wheel slowing down and starting up in speed twice during each revolution, and as the resistance is assumed to be constant, and the periphery speed absolutely uniform, the answer is that "no other than the terminal pressure can be counted in estimating the power delivered." This would be unquestionably true if the piston were thrusting a plunge into a chamber of constant resistance; or against a loaded platform, and when fully understood the conditions will be accepted as being precisely the same. Duly considering the foregoing, it cannot but be admitted that where the resistance is constant, the pressure on the steam piston must be constant. And that where the fly-wheel is sufficient in weight and velocity to maintain a perfectly uniform periphery speed, operated by an engine cutting off at any fraction of the stroke, the resistance becomes practically constant, and only the terminal pressure can be estimated as passing into useful work.

—The paper by James Milne, of Toronto, on the "Steam End of an Electric Plant," was read before the Canadian Electrical Association by C. Lord Weeks, of Toronto. Press of matter has obliged us to omit this paper from the present number of THE CANADIAN ENGINEER.

IMPULSE WATER WHEELS.*

By J. T. FARMER, MA.E.

(Continued from May Issue).

In all these particulars there are some modifications which can be more or less exactly stated: (a) The velocity of the impinging jet is reduced in the ratio of a coefficient of velocity depending on the pipe line and nozzle. (b) Instead of striking the vane tangentially, the jet generally, as in the case particularly alluded to, strikes at a point nearer to the nozzle. (c) The force of impact is reduced owing to the velocity lost by the water in passing over the surface of the vane. Some previous experiments on this subject afford data which will be used in approximating to the loss due to this cause. (d) It is impossible, practically, to turn the water completely back on itself on account of the reaction which would take effect on the back of the succeeding vane.

In practice there will be a reduction of velocity, due to two causes: (1) Resistance of pipe line. (2) Loss in discharge from the nozzle. In the trials under discussion the heads given are those measured close to the point of discharge, so that no loss due to the pipe line need be considered. The only loss of velocity is that which occurs in the discharge from the nozzle. In the nozzles used in the experiments the stream issued from a parallel throat, and consequently there would be no appreciable contraction of the jet. The co-efficients of discharge were determined for these nozzles for heads up to 20 feet, above which point the variation becomes very slight. The results obtained therefore give an approximation to the true velocity of the jet. In addition to these determinations the co-efficient of discharge was calculated from the data afforded by each of the trials. These co-efficients agreed very closely with those obtained directly in the case of the ¾-in. nozzle. The mean values were .972 and .980 respectively. The discrepancy is not surprising when it is considered that in the former case the outflow was from the end of a long pipe, while in the latter it was from a large body of water at rest.

The discrepancy is more marked in the case of the nozzle ½-in. diameter, where the two values are .909 and .976. It is suggested that this difference is due to the fact that the interior of this nozzle was covered with rust at the time of its being used in the water wheel, as it had been in place for some time. The coating of oxide on the interior would diminish the actual area of outlet, so that the co-efficient would appear to be smaller than it actually was. In addition to this there can be no doubt that the rough surface of the oxide would diminish the velocity of the outflowing water; this may be partly the reason why the trials with the ½-in. nozzle show a smaller efficiency than those made with the ¾-in. nozzle. If this explanation is correct, it would point to the desirability of having the interior surfaces of the nozzle tips clean and free from rust. To accomplish this, it would probably be worth while to have detachable nozzle tips made of brass or some other metal not so liable to be acted upon as iron in the presence of moisture. It would also be advisable for the user to periodically take out and clean the nozzle tip, especially if made of cast or wrought iron. With a dirty nozzle there is a direct loss of efficiency corresponding to whatever loss of velocity is caused by the rough surface of the nozzle. More than this, there is a diminution in the area of the outlet, and therefore in the discharge, with the result that the power developed by the motor falls off. This may become a serious consideration if the motor is not much more than equal to the demands usually made upon it.

*From a Paper read before the Canadian Society of Civil Engineers.

From calculations made it was apparent that there is still a waste of from 15 to 25 per cent. of the original energy of the water which has not been accounted for. The loss due to friction of bearings would be small in a simple machine of this sort, and the greater part of the 15 to 25 per cent. loss must be due to some departure in practice of the phenomena of action from those assumed. It is suggested that the loss arises wholly or in part from the imperfect action of the vanes or buckets in turning back the water. It will be remembered that one of the functions of the wedge was described to be to cause the water to be discharged to the side of the wheel. A little consideration, however, will show that during a part of the period of action the wedge does not perform this function. When the vane begins to intercept the jet, it is the outer lip or scoop which first comes in contact with the jet. The small amount of water which strikes the blunt edge of this outer lip is scattered, and thus only gives up a proportion of its energy to the wheel. More than this, it probably causes considerable disturbance and consequent loss of energy in the rest of the stream. As the vane passes further into the path of the jet, the water strikes on the interior curved surface of the outside scoop portion of the bucket on each side of the outer end of the wedge. The curve of the bucket at this point is such that the water is mainly deflected in an inward and backward curve in the plane of the wheel, so that it emerges from the vane surface in a plane tangential to the wheel rim: it proceeds in the same direction until it strikes the back of the following vane, producing upon it a force of impact opposite to the direction of motion of the wheel. As the wheel moves into such position that the jet plays upon the central portion of the wedge, the stream is deflected to each side in a plane parallel to the axis of the wheel, and it is then and only then, that the conditions of action assumed are approximately fulfilled. It may be estimated that the action of the water is not what it is assumed to be while the vane moves over from 1-5 to 1-3 of the total arc of action. During this interval the action of the water is more or less inefficient.

It was noticed that the deficit of the actual from the calculated efficiency increases steadily as the speed is increased. It is suggested that this may be attributed to two causes. (1) The best effect of the impact occurs when the sharp edge of the wedge is perpendicular to the line of the impinging jet. This condition only occurs at one point in the arc of action. At all other points the position of the edge of the wedge departs more or less from the perpendicular position, and the deflection does not take place in the manner assumed, with the consequence that the efficiency of the impact is more or less impaired. The higher the speed of the wheel the greater is the arc of action, and consequently the greater will be the departure of the cutting edge of the wedge from perpendicularity to the line of the jet. This would mean that the loss of efficiency of the impact is less when the arc of action is smaller, or the speed small, and that the loss of efficiency increases as the arc of action increases, or as the speed is increased. (2) It was pointed out how the action of the outer lip or scoop at the beginning of the arc of action tended to impair the efficiency of the wheel. It will be seen that if the arc of action is large enough the same effect will take place at the end of the arc of action, as well as at the beginning. If, therefore, the speed is increased to such an extent as to allow this to occur, there will be a further cause of loss of efficiency at high speeds.

It is estimated that the efficiency would not suffer diminution from this latter cause until the velocity reaches a value of 800 revolutions per minute with the 175 foot head, or a value of 900 revolutions per minute with the 235-ft. head.

I.—Nozzle .5277 in. Diameter. (a) Pressure 50 lbs. per sq. inch. Equivalent head = 115 feet. Discharge = 45 gallons per second:

(Continued in next issue.)

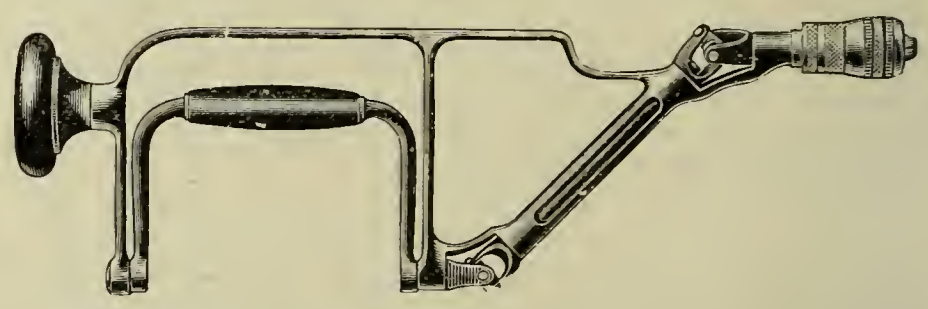
The Geo. White & Sons Co., Ltd., manufacturers of agricultural implements, London, Ont., have completed the new building, 175 x 35 ft., in which it is intended to manufacture threshing machines under rights bought recently from McPherson & Co., Fingal, Ont.

The Hamilton Facing Mill Co. have been running overtime for some months past, and have not been so busy for years as they are now.

The Garlock Packing Co., of Hamilton, have had a very busy season. Among the specialties this company is turning out is a high-grade asbestos covering which is meeting with wonderful success all over the country. The Garlock Packing Co. have won the confidence of engineers and steam users, and this no doubt is one reason why their new line of goods has come into favor so quickly.

THE UNIVERSAL BRACE.

The universal brace needs but little explanation with the practical mechanic, whether he be electrician, plumber, or carpenter; it is rapidly crowding out of the market the old-fashioned and clumsy angle brace, so long the only article of



its kind obtainable. The tool is usually supplied with a bar grip handle, which is specially adapted for overhead and horizontal work. The Aikenhead Hardware Co., 6 Adelaide St., East, Toronto, will be pleased to answer all enquiries as to price, etc., of this very necessary article.

Arc Light Electric Plant

Tenders for Dynamos, Lamps, Poles, Wiring

and all necessary electrical plant for the full equipment of a 350 2,000 c. p. electric arc light plant, together with all the necessary engines, boilers, &c., required for the steam plant to operate same, will be received at this office up to WEDNESDAY, AUGUST 3RD, 1898, where specifications and form of tender may be obtained.

ORMSBY GRAYDON, City Engineer,
London, Canada.

SAMUEL STEVELY,
Acting Chairman No. 3 Com.

To Architects, Engineers, Contractors and Builders:

Owing to the excellent reputation which our "Star Brand" of Portland Cement has acquired, and which trade mark is protected by Government registration at Ottawa, foreign manufacturers have been sending cements into Canada under the name of "Star," which we believe to be inferior in quality, weight per barrel, etc., to our goods, hence to insure the use of the genuine article, we respectfully suggest that in framing specifications you be careful to see that Rathbun's "Star Brand" is specified and used. We guarantee it.

THE RATHBUN COMPANY,
DESERONTO, ONTARIO

FOR SALE

A Small Lot of 9 Moore Steam Pumps

Sizes 3 in. and 1⅞ x 2⅞ in.
350 gals. per hour.

With or Without Hand Levers. At Low Prices.

ERROR IN DRAINAGE PRACTICE.

BY W. M. WATSON.

A person living in a house that was subject to a foul odor reported the nuisance to the town's medical officer, who sent at various times each member of his staff to investigate, and they each laid the blame on the plumbing and sanitary appliances used in the house, but when an experienced sanitary plumber was engaged he looked for another cause to account for the smell, and after using pick and shovel for a few hours, he put on exhibition the reason for the foul odors, which, as usual, was the blocking of the house trap and settlement of the new drains, causing the dumping of the sewage from all the fixtures in the house into the soil under the kitchen.

Another similar, but more serious example of the many hidden dangers, I propose to relate here, showing the evils of using too many drain traps and using drains of too large a size. I was engaged to find out the cause of foul odors pervading the basement of a large factory. There were water closets, urinals and slop sinks on three of the four flats, each and all delivering into one 4-inch soil pipe extending from the drain underneath the floor to above the roof of the factory. Then every fixture was back-vented into a 3-inch cast iron pipe commencing at the basement floor and passing through each story and terminated above the roof. The plumbing and fixtures were of a high class, and well put together, but when some digging was done below the basement floor and the drains and discharge end of the 4-inch soil pipe were exposed to view, it proved that very little, if any, of the stuff coming down the soil pipe had found its way to the street sewer because the careless way the soil pipe was connected to the tile pipe drain made it almost impossible for it to do so, except at a time when there was a heavy rainstorm or when a large amount of liquid was discharged down the interior drains. Fig. 2 is a sketch showing how the drain and soil pipe were connected when found, leaving out the branch that served the basement water closets and which should be shown to join the horizontal piece of soil pipe between the two bends, immediately before it joins the tile pipe. There was a 9-inch tile-pipe drain from the street sewer to about 7 feet inside the building, laid almost at a dead level, including the trap and T pipe, then a 6-inch drain commencing with a hand-hole running trap intended to keep back the sewer gas from all the other parts of the building. This pipe passed under the factory floor for the full length of the factory, with branches to each rain water leader and slop water gully in the yard, having a grade of only about 1 in 100, and clayed joints. The total length of the 6-inch pipe laid under the floor would be over 100 feet, which would be equal to a storage tank holding about 140 gallons. The 9-inch trap would hold about 40 pounds of water, and the water in the T pipe would have to be 1 inch deep before it could in any way move such a bulk of water as rested in the 9-inch trap, and then the liquid only would be able to get round the dip, while the solids would stay in the dip of the trap and choke it. The largest flush a soil pipe would discharge at one time would be 3 gallons, under 30 pounds in weight, and in this case it discharged vertically through a square T, striking the opposite side or bottom of the 9-inch pipe. The sewage then had liberty on account of the drain being level to choose its own road, and of course preferred the easiest, which was to pass backward through the 6-inch trap that only holds about 20 pounds of fluid or half the amount of a 9-inch trap, which would be soon choked and blocked up with solids. The drains being nearly level throughout their whole length they would hold about 50 gallons of sewage in store before a reaction would take place, even if the 9-inch trap was free, and the fluid begin to dribble outwards towards the street sewer. The 50 gallons would therefore generally be lodging in the pipes or wasting away through the defective joints in the sewer pipes and contaminating the sub-soil under the planked floor. The excrements and paper of sewage will, if well distributed among the fluid, dissolve into a liquid in a few days, so that when there is a space, as there was at this factory equal to 50 gallons, acting as a storage and liquefying chamber, they may continue to dispose of the excrements for a number of years through leaking joints and never have a real choke to enable the owners to find out what hidden damage is done to the building and inhabitants. A 4-inch soil pipe can never flush the sewage it delivers through 9-inch pipe traps, because it is about five times larger than the 4-inch soil pipe. The fluid coming down the soil pipe will pass through the largest trap only by soaking through slowly, devoid of any carrying force, which makes it nearly impossible to carry down any substance heavier than water. Therefore to put in a 9-inch

tile trap to serve a 4-inch soil pipe is about the same as plugging up the end of the drain to prevent anything passing through to the street sewer. The 9-inch drain was too large for the work, but it might answer if the soil pipe was made to enter as shown in Fig. 1, and the trap dispensed with, which was unnecessary in this case, and not demanded by any town by-law.

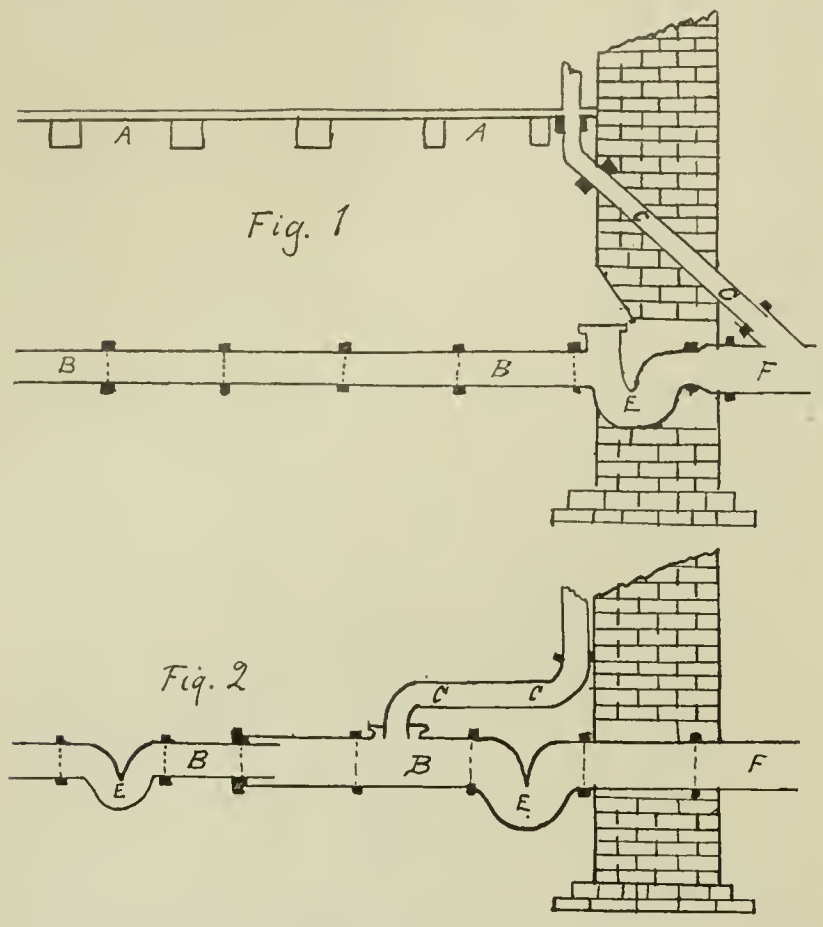

Fig. 1—Plumbing arranged in a satisfactory manner. Fig. 2—Plumbing as actually installed. A A—Factory floor. B B—Tile drain below floor. C C—Soil pipe. E E—Traps. F F—Street drain.

When drains are almost level and in a position as found in this factory, it would be much better and safer to have a reflex flag valve in behind the soil pipe and near the trap, to prevent excrement backing under the factory or the sewage coming back when the flood occurs. No doubt the idea of laying the 9-inch portion of the drain was to leave plenty of room for the contents of the soil pipe when the 6-inch drain was delivering the storm water at full bore, but it was not necessary on that account, because the soil pipe would only deliver occasionally, and then only about three gallons at one time, and that small amount would have very little effect on a stream passing through a 6-inch pipe, and a good rush and flush four times in a year, which is as often as an extra large rain storm comes. When the plumber who did the work, when newly erected, saw the square T junction and 9-inch pipe to connect his 4-inch soil pipe to, he ought to have declined to join the drain in that way. And if his instructions were imperative that the soil pipe should have an intercepting trap and breather, he might have attached a 6-inch, or, better still, a 4-inch hand-hole trap and breather pipe, and after connecting them the pipe might have been coupled to the line of 9-inch drain pipes by a side junction. By making this mistake a large amount of expensive first-class work was rendered dangerous by the error of connecting the soil pipe into the square T junction, and behind a useless 9-inch interception trap, as shown in Fig. 2.

—A correspondent, who is a member of the Canadian Electrical Association, writes to express his admiration of the electrical and mechanical experimental plants at McGill University, Montreal, and to convey the thanks of himself and friends for the courtesy shown by the faculty on the occasion of their visit during the recent convention. Our correspondent was particularly struck with the clearness and simplicity of the answers given by Dr. L. A. Herdt to every question asked by the members when visiting the electrical laboratory. This faculty in Prof. Herdt has struck many others since his connection with McGill. To possess a profound knowledge of a subject and to be able to impart this knowledge in a way that a learner can clearly understand, is a combination of gifts possessed by few. The record which this young professor has already made, both as a practical electrician and an investigator, indicates a most promising future for him, and it should be a peculiar satisfaction to McGill to have a native-born Canadian of such talent at the head of its electrical department.

RESULTS OF EXPERIMENTS ON THE STRENGTH OF WHITE PINE, RED PINE, HEMLOCK AND SPRUCE.*

BY PROF. H. T. BOVEY, LL.D., D.C.L.

In a paper read before the Canadian Society of Civil Engineers, in 1895, the results were given of a number of experiments on the transverse strength of timber beams; but in the calculations it was assumed that the distortion, or diminution of depth at the bearing surface, was sufficiently small to be disregarded. It often happens, however, and especially when the timber contains a large amount of moisture, that the change in depth due to compression is excessive, producing a corresponding increase in the skin-stress. The method of conducting these experiments was fully described in the paper referred to, and therefore the following points only are noted:

All the transverse tests were made with the Wicksteed machine. The middle of the beam was supported on a hardwood bearing of 44 inches diameter. The two ends were forced down by rams under hydraulic pressure, which can be gradually increased at any required rate, or can be maintained constant for any given time. The end-pressures were kept normal to the surface of the beam by means of spherical joints, which allow the end bearings to revolve. In previous experiments, the wire used in observing the deflections was found to be somewhat coarse, and a special wire was therefore drawn of .002-inch diameter.

The flexure theory is admittedly unsatisfactory, and frequently gives results which are contrary to experience. Possibly, when a certain limit has been passed there is a tendency towards equalization of stress, and the so-called neutral surface may be moved towards that portion of the beam which is best able to bear the stress. It may indeed be more correct to assume that the distances of this surface from the tension and compression faces are in the ratio of the ultimate tensile and compressive strengths of the beam. This assumption at all events seems to give results which are more in accordance with practice. For example, in the case of a cast-iron Tee bar, tested in the University Laboratory, the tensile skin-stress should be 22,030 lbs. per sq. inch, and the compressive skin-stress 102,050 lbs. per sq. inch, wheras the ordinary theory gave 33,000 lbs. per sq. inch as the tensile and 20,800 lbs. per sq. inch as the compressive skin-stress.

The following tables give the breaking weights, skin-stresses, (transverse), coefficients of elasticity and specific weights of a number of air-dried, saturated, frozen and kiln-dried beams.

Beams 15 and 16 were sawn out of trees felled at Keewatin in 1894, and were received into the Laboratory on the 13th of December, their weights being 415.75 lbs. and 457.78 lbs. respectively. They were both tested on the 2nd of February, 1895, when it was found that beam 15 had lost 36.69 lbs. or 8.8 per cent. of its weight, and that beam 16 had lost 46.59 lbs. or 10.2 per cent. of its weight. When the beams were sawn through after the test they were still found to be completely saturated with water excepting for a depth of 1 inch from the surface. The beams were from the central portion of the trees, the heart running from end to end. Beams 28 to 43 were sawn from trees felled in water, 1893—4, in Quinze Lake Co., P.Q. They remained in water one year, and were received into the Laboratory on October the 4th, 1895. They were all first quality timber, and, generally speaking, straight in grain and free from knots and shakes. In order to determine the excess of moisture in the timber, three slabs, one near the middle and one at each end, were sawn out of the beams immediately after they had been tested and were at once placed in a chamber kept at a temperature of 212° F. by steam-pipes. The moisture was also removed from the whole beams by drying them in the same chamber. Beam 36 failed suddenly under a very small load, the fracture commencing at a knot in the tension surface. On exam-

ination it was also found that the grain on the face was oblique to the neutral surface, while there were shakes running from end to end in the neighborhood of the heart which, on the average, was below the middle of the depth of the beam. The results of this test should be discarded, as the beam was not of fair average quality. Beam 38 was cut out of beam 36 in such manner that the grain was straight.

Beam 43 failed under a breaking load of 23,000 lbs., but a somewhat long continued and slowly increasing deflection under a load of 22,000 lbs. seemed to indicate that at this point the beam failed in compression, although there were no apparent signs of crippling.

Remarks.—Beams 17 and 18, containing the heart, were cut from trees felled at Keewatin in 1894, and were ordinary 1st-quality timber. There were shakes in beam 17, reaching the heart at points. The grain on the lower half of the beam was straight, but ran cross-wise on the tension surface. From the time the beam was received into the Laboratory to the date of the test, a period of 57 days, the beam lost 13 per cent. of its weight. After the test a 3-inch slab was cut out, and the weight of this slab on Feb. 15th, 1897, by which time the natural drying can be considered to have been completed, was found to be 28.037 lbs. per cubic foot. Beam 18 was tested after remaining in the Laboratory 42 days, in which time it was found to have lost 8.79 per cent. of its weight. It failed by crippling and longitudinal shear, simultaneously. The grain for about 10 inches

TABLE X.

SPRUCE SATURATED AND FROZEN.

33	186	9.2	10	14,000	7,212	6,887	7,050	2,373,080	39.78	30.618	33.55	.....	Crippled.

on each side of the centre was clear, straight and free from knots. The logs from which beams 31 to 49 were sawn were felled in the Bonnechere district in the winter of 1894—95, and remained in the water for six months. They all contained the heart, and were ordinary 1st-quality timber. Beam 32 failed by longitudinal shear along a shake in the neighborhood of the neutral surface, but there were indications that this had been immediately preceded by a slight crippling.

Remarks.—Beams 22, 23 and 35, containing the heart, had lain in the water for a considerable time, and were completely water-soaked. When tested, beams 22 and 35 were found to be hard frozen. Beam 23 was also frozen, but not throughout, as was shown when the beam was cut in two at the centre. Beam 22 was straight-grained, free from knots, and failed with a sudden sharp fracture. Incipient decay had commenced near the heart of beam 23, which, however, was regarded as a fair specimen of ordinary commercial quality. It was full of large knots and the grain was curved from end to end. Beam 35 was straight-grained, clear, comparatively free from knots and of exceptionally good quality; beam 40 was cut out of beam 35 after the latter had been tested. Beams 25, 26 and 29 all contained the heart. Beam 25 was a good specimen, and was completely water-soaked. Beam 26 was saturated throughout, excepting for a depth of 1½ inches from surface, and, although an apparently poor specimen, was considered to be of ordinary commercial quality. It was full of knots and its grain was curved.

Remarks.—Beam 24 was wet, but was in good condition and comparatively free from knots. Beam 27 was of ordinary commercial quality, with fairly straight grain and a large number of small knots. Beam 30 was of ordinary commercial quality, but with large shakes running from end to end and dividing the beam practically into four sections. Beam 33 was water-soaked and hard frozen when tested. It was of exceptionally good quality, free from shakes and had clear, straight grain. Beam 39 was cut out of beam 33 after the latter had been tested.

In the transverse experiments the greatest possible care was taken to increase the load at the same uniform rate, the average time occupied in adding each increment and in taking the corresponding reading being slightly greater than 1 minute. In many cases the beam was loaded, then relieved of load, and reloaded again, the readings in all cases being carefully noted. This operation was sometimes repeated more than once. Whenever a beam or a specimen under tension or compression was subjected to repeated loadings, the first series of readings were almost invariably discarded as the increments of deflection, and changes of length were found to be more uniform after the preliminary loading. The initial loading seems to eliminate certain inequalities of resistance.

In beam 15 there was an increment of .401 inches in the deflection, corresponding to an increment of 7,000 lbs. in the load. On reducing the load to 500 lbs., there was an apparent set of .006 inches, which would have undoubtedly disappeared in a short time. Upon reloading the beam, the increment of deflection for the same increment of load was .4 inch. In beam 17 the increments of deflection under the first and second loadings were exactly the same, viz., .415 inch for an increment of 7,000 lbs. in the load. When the load, after the first series of readings, was reduced to 500 lbs., there was an apparent set of .005 inch, which would have certainly disappeared had the beam been allowed to rest for a few minutes. In beam 24 (Spruce), for an increment of 6,000 lbs. in the load, the increment of deflection was 1.04 inch in the first loading and 1.034 inch in the second. Upon being entirely relieved of load, there was an apparent, but evidently only apparent, set of .01 inch. In beam 25 (Hemlock), for an increment of 6,000 lbs. in the load, the increment of deflection was 1.165 inch in the first loading and 1.155 inch in the second, the apparent set when entirely relieved of load being .01 inch. In beam 27 (Spruce), after being loaded and then entirely relieved of load, there was an apparent set of .005, which in two hours had fallen to .002 inch. In beam 26 (Hemlock), after being loaded and then entirely relieved of load, there was an apparent set of .004 inch which had entirely disappeared after an interval of about two hours.

In the case of beam 28 (White Pine), there were three sets of loadings, the increments of deflection corresponding to an increment of 12,000 lbs. in the load being: .238 inch and .234 inch for the first set, .237 inch and .232 inch for the second set, .237 inch and .232 inch and .232 inch for the third set.

When the beam was entirely relieved of load after the first set, there was an apparent set of .002 inch, which had entirely disappeared in 25 minutes. The second set of loadings commenced after an interval of 18 hours. The mean increment of deflection=.2344 inch; the mean compression=.0827 inch, and, using the ordinary formula, the corresponding value of E=1,066,980 lbs.

The increments of deflection for repeated loadings corresponding to an increment of 6,000 lbs. in the load were: .675 inch, .660 inch, .650 inch, for beam 29 (Hemlock), .335 inch, .330 inch, .337 inch for beam 30 (Spruce), .492 inch, .485 inch, .487 inch for beam 31 (Red Pine), .675 inch, .655 inch, .653 inch for beam 32 (White Pine), .313 inch, .308 inch, .305 inch for beam 49 (Red Pine).

The increments of deflection for repeated loadings, corresponding to an increment of 7,000 lbs. in the load, were: .625 inch, .620 inch, .620 inch, .625 inch for beam 33 (Spruce). The increments of deflection for repeated loadings, corresponding to an increment of 5,000 lbs. in the load, were: .590 inch, .556 inch, .555 inch, for beam 35 (Hemlock).

For beams dried at 212° F., the increments of deflection for repeated loadings were: .420 inch, .400 inch, .405 inch, .405 inch, .405 inch for beam, 36 (White Pine), and an increment of 6,000 lbs. .178 inch, .173 inch, .173 inch, for beam 37 (Red Pine), and an increment of 4,000 lbs. .039 inch, .042 inch, .040 inch, .040 inch, for beam 38 (White Pine), and an increment of 300 lbs. .048 inch, .048 inch, .048 inch, .049 inch for beam 39 (Spruce), and an increment of 300 lbs. .071 inch, .070 inch, .070 inch, .070 inch for beam 40 (Hemlock), and an increment of 300 lbs. .363 inch, .358 inch, .358 inch, .363 inch for beam 41 (Red Pine), and an increment of 1,200 lbs. .669 inch, .672 inch, .675 inch for beam 42 (White Pine), and an increment of 1,200 lbs. .411 inch, .416 inch, .408 inch, .402 inch for beam 43 (White Pine), and an increment of 6,000 lbs. .243 inch, .240 inch, .238 inch, .241 inch for beam 44 (Red Pine), and an increment of 6,000 lbs.

From these results and from the further observa-

tions up to the point of fracture, the following inferences may be at once drawn: (a) The increment of deflection diminishes and therefore the coefficient of elasticity increases with the elimination of the moisture from the beam. (b) The increments of deflection are much more uniform in amount in the case of kiln-dried beams.

It is, of course, impossible to maintain a beam in a kiln-dried state. As soon as it is exposed to the atmosphere, it at once commences to absorb moisture, and the absorption continues until there is an equilibrium between the hygrometric conditions of the beam and atmosphere. The beam is then in its normal state, and the experiments indicate that the increments of deflection, corresponding to this state, are approximately uniform. The rate of absorption depends essentially upon the nature of the timber, and proceeds more slowly as the density increases. The weight of a central 2-inch slab of beam 30 (Spruce), increased 3.6 per cent. in 24 days, and 8.5 per cent. in 47 days. The influence of moisture on the deflection of a beam was well illustrated in the case of 15 inch x 6 inch Douglas fir beam on 186 inch centres. On June 15th, 1895, it was placed in position and was loaded with a weight of 1,000 lbs. at the centre, producing a deflection of .071 inch. The daily observations, extending over several months, showed a continually increasing deflection, until, by the evaporation of the moisture, the beam had attained its normal state. The average deflection now remained constant, varying, for example, between .09 inch on August 24th, and .082 inch on September 2nd, the greater deflection of course corresponding to an increase of moisture in the atmosphere. On the 4th of September, the load was increased to 2,000 lbs., which produced a deflection of .127 inch. This load remained on the beam until January 8th, 1896, the deflection during the same period varying between .129 inch and .114 inch.

Of 20 non-kiln dried beams, 11 failed by crippling on the compression side, 6 failed by longitudinal shear, and 3 hemlock beams only failed by the fracture on the tension side. The experiments on the direct tensile and compressive strength of the timbers show that this is precisely what might be expected to take place. In every case the direct tensile strength is very much greater than the direct compressive strength, and failure by crippling is likely to take place under a load much less than the material could bear in tension. Under all circumstances, therefore, in practice, it is advisable to place a beam so that the portion of the timber which is strongest and in the best condition should be in compression. Again, the experiments conclusively show that kiln-drying enormously increases the direct compressive strength, but greatly diminishes the shearing strength, while the direct tensile strength does not appear to be much affected, although in the majority of cases it was diminished, and sometimes considerably. The large increase of strength in compression due to kiln-drying might have been naturally expected, as in the process of drying the walls of the cells are stiffened and hardened, and thus become better able to resist a compressive force. The walls, however, are at the same time much more brittle, and it is possible that a sudden blow might cause the failure of a kiln-dried column, which would have remained uninjured had the moisture not been eliminated. It may also be of interest to note that in the re-tests of specimens after the injured portion had been removed, the compressive strength was, almost without exception, increased. Hence, by kiln-drying a beam its compressive strength is made to approximate more closely to its tensile strength, and its transverse strength is consequently sometimes considerably increased. It must be remembered, however, that this kiln-drying invariably largely diminishes the shearing strength, and therefore proportionately increases the tendency to shear longitudinally. Thus, of the nine kiln-dried beams in the preceding tables, only one failed by crippling while four failed by fracture on the tensile side and four failed by longitudinal shear. Indeed, generally speaking, kiln-dried beams will fail either by a tensile fracture or by a longitudinal shear, and this result has been further verified by experiments subsequent to those referred to in the present paper.

In practice, of course, beams cannot be maintained in a kiln-dried state, but they rapidly pass into the normal state. The question of how far it is desirable to eliminate the moisture depends essentially on the balance to be maintained between the tensile, shearing and compressive strengths, and a beam should always be placed so as to exert its relative strength to the best advantage. Kiln-drying, unless some special method of prevention is adopted, develops shakes in the timber and causes existing shakes to become more pronounced. Some of these shakes often extend to a great depth and run the whole length of the beam, so that it not infrequently happens that only a slight layer is left to hold the beam together. Such a beam, although otherwise sound and clear, offers very little resistance to longitudinal shear, and might more justly be regarded as being made up of two or more superposed beams.

When this paper was read by Prof. Bovey before the Canadian Society of Civil Engineers, the following discussion ensued:

Prof. Bovey replying to a question stated that the direct tensile strength of timber is much greater in every case than the direct compressive strength, for instance, if 10 represented the tensile strength, 5 would represent the compressive, and for that reason, as his experiments showed, it was always best and safer to put the best side of the timber in compression.

Mr. Peterson replied that while Prof. Bovey's tests indicated that the failure usually took place on the compression side he found that in actual practice the timber invariably failed on the tension side, therefore, he maintained, the direct compressive strength of timber is greater than the direct tensile strength.

Prof. Smith said incipient failure having occurred on the compressive side the neutral axis shifts its position and throws an additional strain in tension.

Prof. Bovey.—A beam which had apparently failed on the tension side, had in reality been first weakened by crippling in compression (which is not always visible), and this threw an additional strain on the tension side, which thereupon ruptured first. No two pieces of timber give the same results, they vary greatly, e. g., if you can cut a piece of timber into three parts longitudinally you will find they vary largely, as far as strength is concerned.

Mr. Irwin pointed out that after a timber had failed the part injured in compression would return so as to escape observation easily, whereas an actual rupture gradually took place on the tension side.

Mr. Peterson said, speaking of bridge trusses, that he had never known the top chord to fail, and that it was not nearly so liable to do so as the bottom chord, therefore it does not coincide with the experiment made.

Prof. Bovey replied that the cases of a bridge truss and a beam of timber were not parallel, and that the top chord of a bridge truss was subject to direct compressive strains very different to those in a beam under the load.

Mr. Duggan remarked that a bridge truss never failed in the solid, but only in the joints, these being the weakest points.

PROGRESS OF CALCIUM CARBIDE.

The manufacture of calcium carbide has been making steady and rapid progress during the past year, and it is satisfactory to note that as the discoverer of the first commercially successful method of production is a Canadian, Canada now takes the lead in its manufacture. In our issues of January, 1896, February, 1897, and January, 1898, as well as in other numbers, historical and technical descriptions were given of the manufacture of calcium carbide and its product, acetylene gas, along with a biographical sketch of the discoverer, Thomas L. Willson, now head of the Willson Carbide Works Company, of St. Catharines and Merritton. A visit of a representative of this journal to the works at Merritton shows that the manufacture of carbide has greatly developed since our last report. There are now three power stations, producing a total of 1,500 h.p. and operating six furnaces, which are running night and day. The export of calcium carbide from these works had last year risen to $22,000, but this year the output will be $50,000, and it only requires sufficiently large factories to multiply this production by ten. That Mr. Willson has always had a most complete faith in the future of acetylene may be inferred not only from what has appeared in these columns from time to time, but from the fact that he ventured an outlay of $250,000 when as yet the character of the public reception of acetylene was a problem. It is no longer a problem, however, for Canadian calcium carbide is now being shipped to the remotest ends of the earth. On the day our representative called a shipment was being made to Hong Kong and another to Shanghai, while just before that a large shipment had gone to South Africa. Two carloads per month now go regularly to New Zealand, while three shipments had been made to the Klondyke, and an offer had just been received from Dawson City for 100 tons to be forwarded immediately. A single firm in Manitoba takes 42 tons per month. The consumption is increasing in each province of Canada and little by little the insurance companies have yielded up the prejudices that existed before the character of acetylene gas became so well known. Recently the Underwriters' Association of Toronto abolished the extra premium of 10 per cent. which had been charged against users of acetylene gas. One remarkable recent development in this gas is its extensive use for bicycle lamps. For use in this line of lighting alone three car loads were recently ordered by one Canadian firm, and this consignment was expected to be exhausted in two months. In Toronto, where cyclists are not compelled to carry lamps at night, there is comparatively small consumption for this purpose, but in Montreal, where the city by-laws require each wheelman to carry a lamp at night, the popularity of the acetylene bicycle lamps is remarkable. The contrast between an acetylene and oil lamp is very striking. The oil lamp, which is only used by about one out of five in Montreal, makes a very dismal gleam by the side of the acetylene gas lamp. Four ounces of carbide will last seven hours in a bicycle lamp, the carbide being retailed at 25 cents for a 2½ pound can. The cost varies from ½ a cent. to 1 cent per hour, and apart from the brilliancy of the light a charge will last much longer than a charge in an oil lamp. Some very convenient students' lamps are now being put on the market for acetylene, while its use for domestic lighting generally is steadily increasing. We have before referred to the fact that the explosive power of acetylene gas in gas engines is much greater than that of oil or gas. While of ordinary gas 18 to 20 cubic feet are required to produce a horse-power, the same power can be obtained from 5 cubic feet of acetylene gas. Acetylene therefore yields about four times the power of other gas. To put the question in another shape, a great saving of space and weight can be gained by the use of acetylene gas engines, and for light power these engines can be built so small as to be practically noiseless. As compared with coal a given power can be obtained from about one-seventh of the weight of carbide. That is to say, where about seven pounds of coal are required per horse-power, one pound only will be needed of carbide, a pound of the carbide producing five cubic feet of gas. The explosions from acetylene are quicker than from coal gas or oil, and consequently greater speed can be obtained. Our readers may be interested to know that the Union Carbide Company of Chicago have bought the plants at Niagara Falls, at Sault Ste. Marie, Michigan, and in Virginia, the united company being capitalized at $6,000,000 or $8,000,000. Large developments are in consideration in Canada, also, and at Grand Mere, in the Province of Quebec, a water-power capable of yielding 100,000 horse-power has been acquired to extend this interesting industry. The promoters have unlimited capital at their back, among those interested being William McKenzie, the well-known capitalist of Toronto.

ASSOCIATED PLUMBERS' CONVENTION.

The second meeting of the National Association of Master Plumbers of Canada was held at Quebec on June 29th and two following days, Joseph Wright, of Bennett & Wright, Ltd., being in the chair. By carefully reading the reports of the officers and committees and the minutes of the business done during the three days' deliberations of the association, the public will come to the conclusion that its interests appear to be taken into scant account. The published reports show that the chief aim of the meeting of the association and the previous executive meetings was to create a monopoly in the trade for the benefit of the members and to make rigid rules which would bring all the trade into line with the combination. There is a total absence in the asociation's discussions and the officers' reports of subjects touching on improved sanitary methods and scientific plumbing, heating or gas fitting.

If the proceedings of the Associated Master Plumbers of Canada, so far as made known, be a sample of the treatment the public may expect at their hands, then we must accept the association as a combination in restraint of trade, whose aim is to increase its members' profits at the expense of the public liberty and purse. It is quite legitimate and even commendable for trades and business men to associate together, and combine their influence, knowledge, and advice, to protect themselves and to exchange ideas with each other with a view to raising the standard of the trade and improving the class of work and remuneration, but when associations make it their business to interfere with the liberties of others and damage private enterprise by using their combined strength to compel others to adopt their views, rulings and methods of working, or retire from business, it is quite time that the public should make its voice heard in the discussion. The report leads us to believe that this association intends if possible to secure Acts of Parliament and by-laws in every town that will enforce the Master Plumbers' Association's dictatorship on the population of this country, which is already sufficiently ruled and regulated. The city of Toronto appears to be the birthplace of the association, and during the past few years we have been able to note

how such a monopoly works, and therefore gather some idea of what may result when the association fully develops and its rules are enforced by the Legislature. When the Toronto association was only a few months old, and standing alone, it persuaded the Toronto city council to embody some of its ideas in by-laws, and no person was permitted to commence or carry on the business of master plumber or do a job of plumbing work on his own account, except he passed the Toronto Board of Plumbers' examinations and had an established place of business. The board consisted of Joseph Wright, W. J. Burroughs, master plumbers, and E. J. Lennox, city architect. This body has also the privilege of saying who was qualified to fill the appointment of inspector of plumbers' work and enforce the city by-laws. It will be obvious that such extensive powers in the hands of business men require the most judicious and conscientious exercise, and that even then friction would be occasioned. The journeymen were to be examined also, but a strike made it impossible to carry this out and the idea was dropped.

Some difficulty has been experienced in enforcing the Toronto by-law, and in some cases the city has failed to secure convictions under it, though there was no doubt that the defendants were not licensed and were carrying on business as plumbers. We find by the reports of the Quebec meeting that the difficulty in compelling all plumbers to enter the combination is about to be overcome in another way. The manufacturers of plumbers', gas and steam fitters' supplies must act in harmony with the Master Plumbers' Association of Canada and agree to sell goods at manufacturers' prices only to members of the association. This will practically prevent anyone doing business who can not or will not join the combine, because he will not be able to secure the necessary material at trade prices. We may also expect that in time the license fee will be advanced to an amount that will prevent anyone but a capitalist paying it, and thus prevent those who have served an apprenticeship, but are not fortunate enough to possess the money to pay the license fee, from taking the advantage of their years of education and work. We have also observed the great difference in the two tenders for the plumbing and heating of the new city hall, Toronto, the one being made at the time the other contracts were let, and the other accepted a few years after, when the Toronto Master Plumbers' Association had had time to get its members into line.

WHO IS "EXPERT"?

I notice in your last issue that John McDougall, the agent for the International Sewage Purification Co., demands my name. It is Henry Lee McKinstry, born at Armagh, Ireland, my father being a land owner there and medical health officer for the district. I, myself, was formerly a traveler in England representing a wine manufacturing syndicate, and I came to Canada a few years ago with the intention of learning the habits and customs of the people, and the value of the land, the products, minerals, etc. I hear and secure considerable information on many important subjects and know probably more about sewage purification and the international system than Mr. McDougall does himself, and I am prepared to prove every word spoken in the letter complained of, and to discuss sewage purification with Mr. McDougall in any public hall, after November 15th, when I propose to make a long stay in Toronto, and allow the audience to say by show of hands whether Mr. McDougall or myself is the most competent person to judge such an important subject. I have no interest in any sewage scheme in this or any other country, or desire to interfere with any private or public business, nor am I acquainted with Mr. McDougall or any other agent, but when I became acquainted with all the facts of Mr. McDougall's offer made to a special committee of Toronto City Council on March 17 last, I thought I was only doing right, with the experience and knowledge I possessed of the subject in England, to say a few words that would help the public to judge intelligently for themselves in Canada. Being a British subject and living until lately on the tight little islands of England and Ireland, I naturally supposed that the general public of a British colony possessed certain lawful rights of criticism, and that when a drummer made an offer to sell goods to the representatives who had to pay the bills, that the public or any single individual might point to errors, or discuss the value of goods or systems offered to the public without being threatened by the vendors or their agents. I suppose Mr. McDougall will bring Chas. G. Horetzsky, C. E., to task in the same way for the letters he has published in the London, Ont., Advertiser on the same subject. I think it is now time that Mr. McDougall and his principals proved at least one-tenth of the statements which they make in their printed pamphlets about the efficiency of their systems now working in Great Britain, and any Canadian municipality that wishes to protect the health and interests of its constituents should at least have wisdom enough to send an experienced and disinterested person to England to investigate a system upon which it proposes to spend thousands of dollars. It is now in Mr. McDougall's power to prove to the public and the press whether he or I am the biggest coward, and whether the system which he is pushing is an efficient purification system or a financial success.

H. L. McKinstry.

Toronto, July 20th.

NEWFOUNDLAND COAL.

Very favorable accounts have been received from the new coal mines near Grand Lake, Newfoundland, now being opened and worked under the Reid contract. Extensive borings have been made on three of the seams resulting most satisfactorily, the quality of the coal being excellent, and the thickness of the seams increasing. The Imperial Institute, in a circular recently issued, furnishes the results of an analysis of this coal. A small sample, about three ounces, had been sent to the institute from the 6 feet seam for analysis. The circular states that the coal was found to be bright, clean and tough, presenting an irregular conchoidal fracture, and the following results on analysis :—

Fixed carbon	47.19
Ash	10.82
Coke	58.01
Volatile matter	41.99
Sulphur	.735
Calorific value	6347.

The sample caked fairly well, furnishing a coherent, somewhat brittle, coke. The ash is nearly white. This will probably prove to be a good heating coal of fair quality, containing very little sulphur, though rather a low proportion of fixed carbon.

Number two sample from 2½ feet seam weighed about two ounces. The coal was dull, rather brittle, but clean and not dusty. The analytical results were as follows :—

Fixed carbon	49.32
Ash	13.05
Coke	62.37
Volatile matter	37.63
Sulphur	.62
Calorific value	6435.

The coal burns slowly and cakes fairly well, furnishing a somewhat brittle coke. The ash is gray. This coal closely resembled the former sample. It must be remembered, too, that these are almost surface specimens and the coal is likely to improve as the mine deepens. Should the coal seams develop according to expectations it is needless to say that the benefit to the colony will be immense.

—In a lecture before the London Chamber of Commerce, Wm. Ogilvie spoke very plainly about the way in which his name and his reports had been used by promoters for their own ends. He said : "My name has been quoted pretty prominently in a great many prospectuses, and I have been made to say a good many things that I have never said at all. I simply say this as a warning : Do not pay the slightest attention to any extracts from my reports. They may be correct quotations, but they are often misleading. I have no interest in any company ; my sole object is to benefit my own country, Canada, and the Empire of which it is a portion."

MINERAL PRODUCTION OF THE UNITED STATES IN 1897–8.

(PRELIMINARY STATEMENT.)

Compiled for THE MINERAL INDUSTRY, Vol. VI.

By Richard P. Rothwell, editor of the *Engineering and Mining Journal.*

UNITED STATES MINERAL PRODUCTION IN 1897.

We give in the accompanying table the completed statistics of the production of minerals and metals in the United States, as collected and arranged for Volume VI of "The Mineral Industry," which is now in press. The total value of the mineral production of the United States in 1897 was, therefore, $746,230,982, against $737,958,761 in 1896. The values given are generally at the mine or works; but with a few of the principal metals—such as lead, copper or zinc—this is not possible, and their values are taken at the leading markets. The total value of the output in 1896 exceeded that of the mineral and metal production of all continental Europe, and nearly doubled that of the United Kingdom, the value of whose mineral output in 1896 was, in round figures, about $340,000,000, while that of Germany was about $300,000,000, that of France about $110,000,000, and that of Belgium $100,000,000.

Deducting necessary duplications, we find that the total value of the production of the United States in 1897 reached the sum of $678 966,644.

This output is limited entirely to ores and other substances mined in the United States and to metals reduced from those ores. In addition there was also a large quantity of metals reduced or refined in the United States from imported ores or base bullion. These are chiefly sent here for treatment from Canada and Mexico. The total production of this class reported was 584,983 ozs. gold; 40,218,776 ozs. silver; 26,938,254 lbs. copper; 4,099,390 lbs. nickel; 92,117 short tons lead; the total value of these metals being $47,127,174. This output of metallurgical works is altogether additional to that recorded in the table. These metals were obtained chiefly from ore, bullion, furnace products and silver-lead imported from Mexico, Newfoundland and Canada. A comparatively small amount of gold and silver ore and bullion comes from Central and South America. Also there was received a large amount of pyrites from Spain and Portugal, all of which contains a little copper. From British Columbia and Mexico came chiefly lead-bearing ore and silver-lead, from which a large part of our lead supply is obtained. The nickel is all from ores or matte produced by the mines at Sudbury, Ont. We have not included in the above quantities the iron smelted from foreign ores, which is small in actual amount and insignificant in comparison with the total output; nor have we included the manganese in foreign ores which enters into the composition of the spiegeleisen and ferro-manganese that is made in the United States. The lead industry is the one most affected by the foreign material that is imported, the quantity of copper being comparatively small.

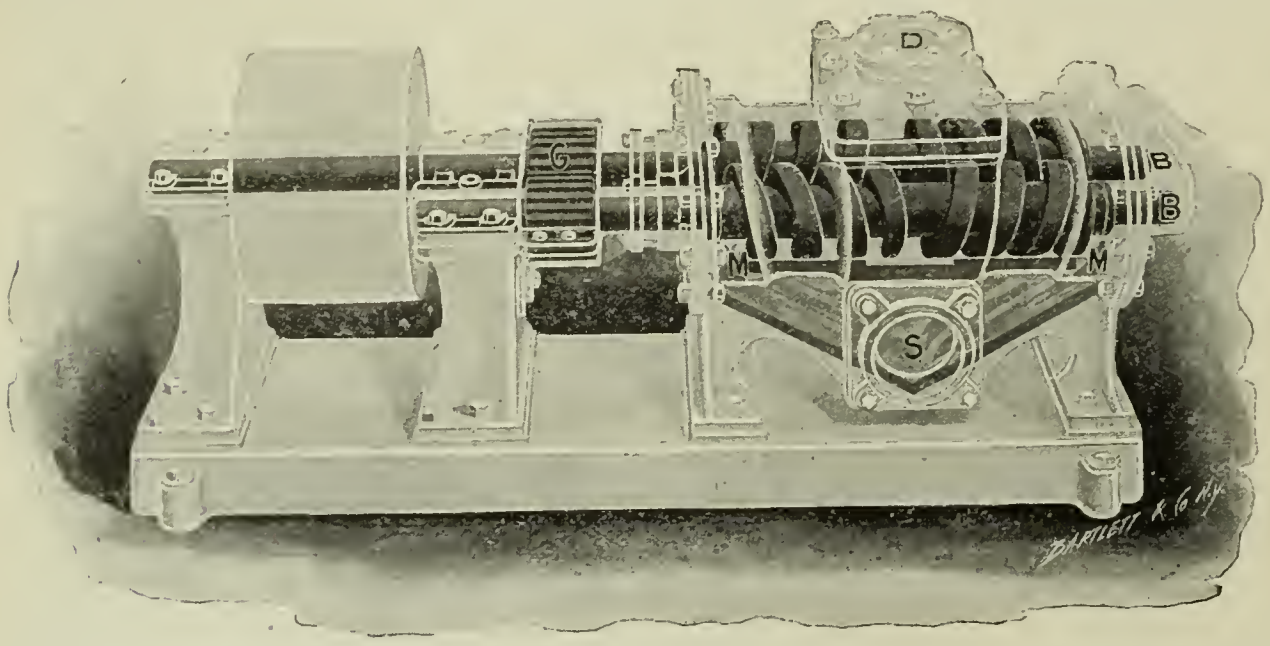
We have given the production of the different articles in metric tons (or kilograms in the case of precious metals), as well as the customary measures, for the reason that the metric measures are those recognized and used by almost all of the civilized world, and are rapidly gaining recognition in the few remaining countries which have not yet fully adopted them. In the United States they are already legalized, with the prospect of their compulsory and exclusive use at an early date. How desirable such a change will be can be best appreciated by those who have had occasion to collect or use statistics of this kind.

THE QUIMBY SCREW PUMP.

By W. T. Bonner, Montreal.

The novel feature of the pump is its simplicity, utilizing as it does a very simple mechanical principle in a very unusual manner for performing useful work.

As will be noticed by an inspection of the accompanying illustrations, the Quimby pump consists of two parallel shafts, on which are mounted the four screws that act as pistons in propelling the water, so arranged that in each pair the thread of one screw projects to the bottom of the space between the threads of the opposite screws. The screw threads have flat faces and peculiarly undercut sides; the width of the face and

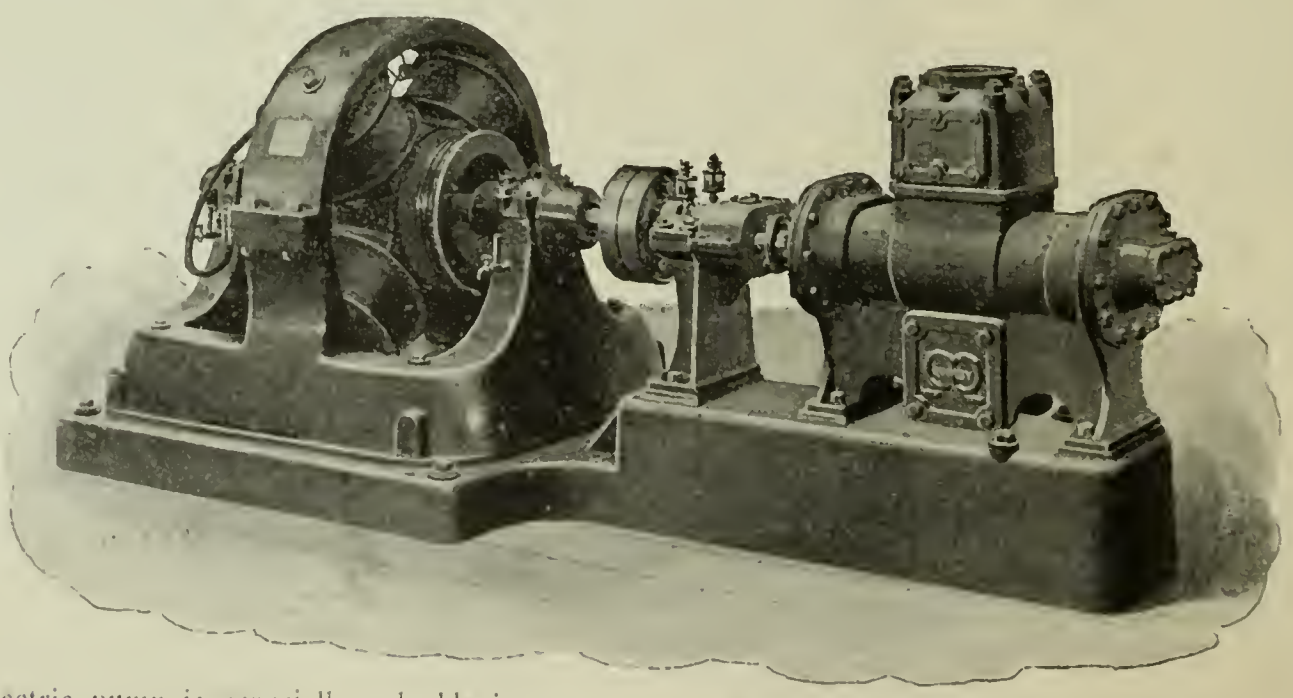


the base of the thread being one-half the pitch. The pump cylinder fits the perimeters of the threads, as shown in figure 2. Space enough is left between the screws and the cylinder and between the faces of the intermeshing threads to allow a close running fit without actual contact. There is no end thrust of the screws in their bearings, because the back pressure of the column of liquid is delivered to the middle of the cylinder, and the endwise pressure upon the screws in one direction is exactly counterbalanced by a like pressure in the opposite direction. The suction connection is shown at S in Fig. 1, and opens into a chamber underneath the pump cylinder. The power to drive the pump is applied to one of the shafts, and the second shaft is driven by means of a pair of gears, shown at G in Fig. 1. The pump has no internal packing, no valves, and no small moving parts.

used in connection with the gravity system, the pump section is connected with the lower discharge tank, and the discharge from the pump is elevated into the roof tank. The pump is controlled by means of a float in the discharge tank, and a starting box.

The Quimby electric pump, when applied to an elevator, can be automatically operated, thus doing away with the constant care and attention required by a steam pump. Whether operated by belt or direct connected to electric motors or steam engines, the Quimby pump has many advantages. For waterworks, oil refineries, or other service where liquids are pumped through long pipe lines, any pulsation in the delivery adds to the difficulty of maintaining tight joints. The Quimby pump, however, has an absolutely pulseless delivery, and at the same time a very high efficiency. Long series of tests show an average efficiency of more than 55 per cent. from wire to water. In many instances tests have shown as high as 65 or 66 per cent. efficiency.

The pump will readily handle thick products, such as paraffine, hot tar, pitch, white lead, melted sugar, glucose, soap, lard, etc. For this service, reciprocating pumps are not desirable, for the reason that heavy liquids are likely to be churned by the action of the plungers, and the friction of the material passing through the valves and ports, greatly reduces the capacity and efficiency. Altogether the Quimby pump appears to offer a wider range for the utilization of electric power than any other apparatus presented for some time past and in a field also where cost of installation and operation are both very important factors.



The Quimby electric pump is especially valuable in connection with the hydro-electric operation of elevators. When used in connection with the pressure tank system, the suction is connected with the elevator discharge tank, the pump discharging into the pressure tank. The pump is controlled by means of a pressure regulator and starting box. When the pressure in the tank falls, the regulator operates the starting box and the pump runs until the pressure has been restored in the tank to the required number of pounds. By the peculiar construction of the Quimby pumps there is no pulsation. When

*Extract from a paper read before the Canadian Electrical Association.

W. Edmonds, contractor, has begun the brick work of the addition to McDougall's foundry, Galt, Ont.

The output from the Chicoutimi, Que., pulp mills is to be exported from Quebec, a steamer being loaded every second week.

The Brockville, Ont., city council has purchased a site for the factory of the Brockville Provision and Packing Company. Plans and specifications are being prepared by Montreal and Chicago experts, and an extensive plant including first-class cold storage facilities will be installed.

THE STEAM END.*

BY JAMES MILNE.

In a paper read at a former convention of this association, it was stated that purchasers of electrical apparatus made very careful enquiries as to the efficiency of same, the price being of secondary importance. If this applies to the electrical, why should it not apply to the steam end as well? I am sure that there are very few plants where the proprietors, or those in charge, enquire as to the efficiency of the boilers and engines, the price with these items being the very first consideration, generally. It is very seldom, in specifications for steam plants, that there is anything said about the efficiency of the boilers, or the water consumption per horse-power at the engine. This I consider one of the most important points in connection with the steam plant. There are engines running which are supposed to be first-class and up to date, where the water consumption per horse-power is nearly double what it ought to be, and if the management in some of these plants would go to the trouble of calculating the coal consumption per electrical horse-power at the bus, I am of the opinion that the results obtained would simply astonish them. I, myself, have records of the coal consumption of a plant, together with the total meter readings, extending over a number of years, and allowing for the loss on the line, together with that on the generators, and although the plant was a non-condensing one, yet the records there are not out of the way. In another plant where I was making a two days' test as to the relative values of coal, I found the coal consumption per E. H. P. at the bus just double the former plant, which might be considered high by some. This second plant was condensing. The load was of such a nature as to make the engine very unsuitable for the work.

I am inclined to think that builders of engines should be made to guarantee a certain steam consumption per indicated h.p. at say 25 per cent. over-load, full load and half load, and that tests should be made to determine if the guarantee has been fulfilled. If the guarantee has been more than fulfilled, let a bonus be given to the builders, and if not fulfilled, so much to be deducted for every 1 per cent. below the guarantee; and if it falls below a certain amount, that is to say, the steam consumption exceeds a certain fixed value, the engine to be removed, or the builders to accept a nominal figure for same. I think if means of this kind were adopted we would get engines of a very high order. Engineers, as a rule, are content so long as they get a fine looking card from their engine, but they very seldom from these cards calculate the steam consumption, which is of vital interest. We have quite a large number of good engine builders in the country, but the number guaranteeing their efficiency is very limited indeed; in fact, I am not aware of any. If tenders are invited for a certain style of engine and the tenderers are called upon to guarantee the steam consumption per B. H. P., the party to receive the contract is the one guaranteeing the least steam consumption per h.p. hour, the cost being of secondary importance. After the engine has been installed and run for some time so as to get down to its proper bearing, carefully conducted tests should be made to ascertain if the guarantee has been fulfilled.

The matter of efficiency of boilers is also one of great importance, but it is not so easily arrived at, owing to the difference in coal. At the same time, however, it would not be a very difficult matter to fix on a certain coal for a standard, and to guarantee so many pounds of water evaporated per lb. of that coal. All boilers, I believe, should be sold by the Centennial Standard, and should be capable of developing their rating with easy firing, showing good work with ordinary coal, and should be capable of being forced 50 per cent. above their rating. There was a recommendation something to this effect made by the Committee of Judges at the Centennial Exhibition, the horse power being 34½ lbs. from and at 212 degrees, which is equivalent to 33,305 heat units. We should get an efficiency close on to 80 degrees with good boilers, and this could be roughly determined with anthracite coal, and if we get 12 lbs. of water evaporating from and at 212 degrees, we have approximately this efficiency, the heating value of the combustible being about 14,500 heat units, which is equivalent to 15 lbs. evaporated from and at 212 degrees, therefore 80 per cent of this gives us 12 lbs. With bituminous coals we have not such uniformity, and it is necessary to determine its heating value either by the coal calorimeter or chemical analysis.

After our boilers and engines are installed, we have to face the problem of running them. It has often been stated that men could be got to do anything, men being more easily replaced than machinery, costing practically nothing as it were. I am of the opinion that this is wrong. Cheap men are numerous we know, but are in the long run very expensive. Good men are scarce, and nowhere is this more noticeable than in the boiler room. Good firemen are very scarce, coal shovellers numerous. In my humble estimation, credit is not given to the firemen that should be. If a plant is run fairly economically as far as coal consumption is concerned, the engineer is more apt to get this credit, but as a matter of fact all he does is to turn on the steam and see that the bearings are oiled. Now and again he may walk into the boiler room to ascertain if the fireman is asleep or not. To have good firing the greatest of skill has to be manifested to get the best results from the coal, and where we are dependent on skill to get first-class results we are depending on a very uncertain quantity. Too much latitude is given the fireman in the matter of coal, and he has it in his power to make or lose nearly a dividend for the company that employs him. Attention is being given to this subject by the largest steam users in the country, whereby the duties of the fireman are being greatly relieved by mechanical devices; their action being positive and not dependent on skill, the machines thus taking the place of the brains of the fireman. This you will agree is a great step in advance, and makes central station management very independent regarding firemen.

*A paper read before the Canadian Electrical Association.

IMPULSE WATER WHEELS.*

By J. T. Farmer, Ma E.
(Concluded).

II.—Nozzle .7532 in. diameter. (a) Pressure 75 lbs. per sq. inch. Equivalent head = 175 feet. Discharge = 120 gallons per minute.

Speed.	Horse Power.	Efficiency.
402	3.68	58.5
501	4.10	65.0
618	4.34	68.8
675	4.34	68.9
750	4.33	68.7
770	4.30	67.7

(b) Pressure 100 lbs. per sq. inch. Equivalent head = 235 feet. Discharge = 138 gallons per minute.

Speed.	Horse Power.	Efficiency.
370	4.82	49.4
371	4.86	50.0
475	5.67	58.4
515	5.95	60.7
588	6.20	63.9
654	6.60	67.8
698	6.66	68.6
756	6.88	70.8
815	6.72	69.3
911	6.35	65.6

In connection with the above results it is interesting and important to notice that the highest actual efficiency appears at a speed which is about .9 of that which theoretically should give the maximum efficiency.

A most important difference between an impulse water wheel and a turbine of either the impulse or pressure type is that the construction of the latter allows a larger area of water to be applied to the wheel for the same dimensions of wheel. In the turbine the wetted surfaces bear a much larger proportion to the size of the wheel than in an impulse wheel, and those surfaces in the turbine are constantly in action, while in the impulse wheel their action is intermittent. When the head of water is small a correspondingly large quantity has to be used to give a required horse-power, and in this case the turbine has the advantage of passing a much larger quantity than the impulse wheel. When the head is very large this feature of the turbine becomes a disadvantage, as it becomes a difficult

*From a Paper read before the Canadian Society of Civil Engineers.

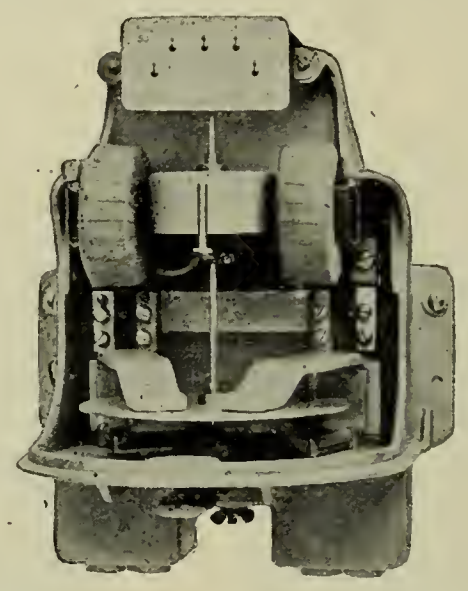
problem to curtail the total discharge of water so that the total power developed may be handled without mechanical inconvenience by the working parts of the motor.

In order to develop considerable power, with a comparatively small head using an impulse wheel, one of two things must be done: either the area of the nozzle and consequently that of the vanes must be made very large, which is only practicable to a limited extent, or else the number of nozzles and wheels must be multiplied. Thus the use of impulse wheels under small heads involves a large amount of machinery for the power obtained. On the other hand, the impulse wheel has many points in its favor, chief among which is its simplicity of construction, which leads directly to the absence of mishaps and to ease of maintenance. The bearings are simple, being merely those on the horizontal shaft, in such a position as to be easily got at when necessary to make any repairs or adjustments. There are no bearings running under water; and the bearings are not subject to any other reaction than that due to the useful effect of the water on the wheel; no difficulty is met with corresponding to that of balancing the static pressure of the water on a turbine, which becomes such an important problem when large heads are being used. The impulse wheel has no watertight joints, as there is no water pressure to be maintained among the working parts. The mechanism also does not contain any parts which are likely to work loose or otherwise become deranged and so lead to trouble.

An important point in determining the practical usefulness of water motors is their adaptability to be run with a fair degree of efficiency under a fraction of the full load. This state of things is generally liable to occur either intermittently, as where a number of loads are being continually put on and off the mechanism driven by the motor; or periodically, as where for portions of a day or week or year the work required from the motor is heavier than at other times. Three methods will be mentioned which are employed to vary the output of work from the wheel. It was mentioned that three nozzle tips of different sizes were supplied with the wheel with which the tests were made. By changing these the quantity of water discharged under a given pressure can be varied as the area of the orifice. The power of the jet will consequently vary in the same ratio; and so any change of load which can be anticipated and will last for a considerable period can be provided for. The changing of the nozzle tips need not be a very difficult operation. It is, however, a very inconvenient plan to have to resort to to regulate the output of power from the wheel. These wheels are sometimes built with several nozzles placed at intervals round the periphery of the wheel. When this is the case the power can be reduced by shutting off the stream from one or more of the nozzles. The third method is to employ a valve or gate in the supply pipe which can be shut off to any desired extent by hand or by some automatic regulating machinery. This method is almost always necessarily employed in addition to those aforementioned. It will be noticed that the effect of the valve to reduce the power is reached by throttling the water as it passes the gate, thus reducing the pressure of the water as it reaches the orifice and consequently reducing also the discharge. It need hardly be pointed out that there is a great loss of efficiency when the motor is running under a light load, as the pressure energy which is not required to drive the machine is all absorbed without useful effect in the resistance of the partially closed valve. An idea of the actual efficiency reached can be gained from a consideration of the foregoing results, obtained for the small nozzle, for the range of heads from 120 to 300 feet. In calculating the efficiencies previously given, the available work was calculated on the assumption that the pressure under which the test was made was the total pressure available. But if that pressure is not the total available pressure as when the pressure is reduced by throttling from 125 to 100 or 75 lbs. per sq. in., then the total available work must be considered to be the product of the weight of water used and the head equivalent to the total available pressure before any throttling took place. In the preceding remarks an attempt has been made to describe and discuss the action of impulse water wheels, and more particularly of the wheel on which the experiments described were carried out: the question of efficiency has been illustrated and examined, and the advantages and disadvantages connected with the use of such a system have been pointed out. It is hoped that these notes may throw some light on this interesting and important subject.

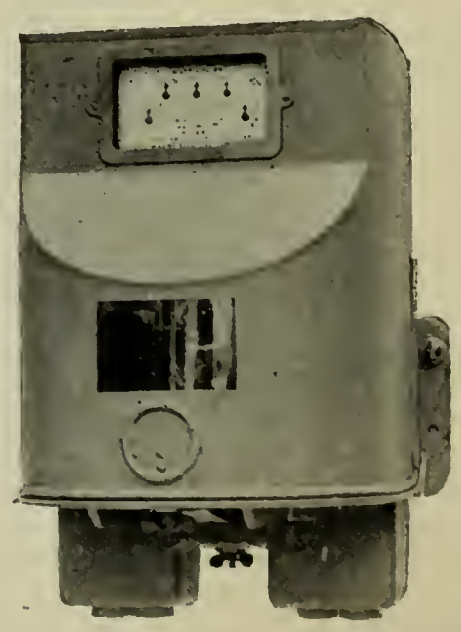
DUNCAN INTEGRATING WATT METER.

This instrument embodies all the essential points that go to make it perfect in every respect. Its operation, like the lamp and ampere hour meters made by the Fort Wayne Electric Corporation and which are giving such good satisfaction, depends upon the induction principle, so that it is very simply constructed and entirely free from any commutator, brushes or other rubbing contacts. It is also the lightest and most compact induction watt meter on the market, so that it is very easily handled and installed. It also has an accuracy on all loads that is excelled by none. When once standardized it will remain accurate for years, this being due to the permanent



magnets forming part of the retarding device being artificially aged by a new process. Another feature that readily recommends it, is a variable friction compensator with which it is equipped. This is something entirely new and provides for cases where the meter should run slow on one lamp after being installed some time, due to the jewel becoming rough. This is a complaint so familiar to the users of electric meters that it does not require to be dwelt upon here. Suffice it to say, however, it does the work and does it well, and without interfering or modifying the speed on any of the other loads. This meter is also applicable to systems having a varying rate of alternations due to uneven speed of the motive power, registering with extreme accuracy.

The principal elements employed in its construction are: Series coils that are mounted upon a laminated iron core which forms the greater portion of the magnetic circuit; an aluminum closed conductor or armature in the form of an inverted cup; and a shunt or volt coil mounted inside the said aluminum armature. The series coils are traversed by the main currents supplying the lamps or other translating devices, and magnetize the iron core in proportion to the amount of current through them. The volt coil is traversed by a current proportional to the electromotive force of the circuit, and is caused to lag



behind the pressure by the addition of an impedence coil connected in series with it. This lagging or difference of phase between the magnetisms of the series and shunt coils causes them to combine into a common resultant which rotates the aluminum armature with a torque proportional to the watts. To make the speed correct and reliable, an aluminum disc is mounted upon the spindle with the armature and rotated be-

tween the poles of permanent magnets, the resulting action of which gives a speed exactly proportional to the watts or energy passing through the meter. The meter is made by the Fort Wayne Electric Corporation. One of these instruments is being presented to the electrical department of McGill University by the Fort Wayne Electric Corporation. It is a 10-light, 66-cycles, 125 volts kilowatt hour meter.

THE IMPORTANCE OF PROPER METHODS OF ILLUMINATION.*

BY F. A. BOWMAN, A. I. E. E., NEW GLASGOW, N. S.

In the last few years, since the electricity supply business has got beyond the stage of "systems" and controlling patents, there has been accumulated a great deal of most valuable information in regard to improvements in the generating and distributing plant, and to the best methods of realizing in practice the benefits from these improvements. From time to time there have arisen most animated discussions on the best system of rates, and methods of charging for the use of the current. The keynote of these discussions is the fact, brought to light by the accumulated experience of those companies that have been supplying electricity for some years, that the fixed charges grow steadily with the maximum demand on the plant, and that therefore the customers should be educated to use the current as many hours per day as possible. This is a matter of the most vital importance, and every central station man in this association should procure a copy of Mr. Arthur Wright's paper on "The Profitable Extension of Electricity Supply Stations," read before the National Electric Light Association at Niagara last year, and also one on the "Cost of Electricity Supply," read by him before the Municipal Electrical Association in England, and to study them until he knows them by heart.

It should be distinctly borne in mind, especially by the smaller companies, that to do a growing and really successful business, something more is necessary than to merely induce your customer to put in so many lamps and then to get as much pay as you can from him for them. It is now clearly demonstrated beyond a peradventure that the margin of profit is as narrow in the central station business as in any other, if not a great deal narrower, and that even when there is no competition from gas or a rival company the closest economy and best management are necessary to yield a profit to the shareholders and provide for future contingencies. In view of this the manager should realize that he must educate his clientele and give them the best satisfaction in every way. Too many managers are satisfied when they have succeeded in persuading a customer to take a certain number of lights. If in addition they are giving full pressure at the lamps and a reliable service they consider that their duty to both the company and the public is done. Now, this is a wrong principle. Attention should be paid to the purpose for which the light is required. Take for example a shop. The purpose for which it is to be used, its size, the height of ceiling, finish of the walls, kinds of goods to be displayed and sold, arrangement of counters and show-cases—all must be noted and considered. It is useless to attempt to light a modern drug store and a ready-made clothing store in the same way, and expect equally satisfactory results in both cases. The manager should be looked upon as authority on methods of lighting, and if he gives the matter a reasonable amount of attention he very soon will be. He must remember that he is a dealer in light and to be a successful one must know all about it—how it is best used and what are the latest fashions in it. If you go to a tailor for a suit of clothes you expect him not only to sell you the cloth and to make up the suit so that it will fit you fairly well, but you expect him to be able to tell you what are the latest styles and fashions and which of them are best adapted to the purpose for which you want them. Some managers will say, "Oh, I have a class of customers who do not care about fitting up nicely and will not spend money on it. All they want is that I will run the wires in and hang the lamps on cords as cheaply as possible." This man is mistaken. There is no community that will take electric light at all where a decided amount of education cannot be carried out. Education of his customers is a very material part of the work of every successful manager in the electrical business, and is one of the principal reasons why the business cannot be properly carrried on by some one who has a number of other interests to look after as well. The manager must study this question of proper illumination so as to master the main principles necessary to a clear understanding of it. He must study his customers so as to know what their tastes and requirements are. He must carefully watch the advertisements in the technical journals and the catalogues that are so plentifully distributed, and many of which contain accurate and valuable information, and then correspond with the advertisers to see if the articles that strike him as suited to some of his customers can be brought within their reach. Then he must canvass carefully and patiently, and if he fails one year must try again the next, because by that time he will know better how to work, his customers' ideas will have advanced somewhat, possibly prices will have dropped a little. The net result of all this is that he at last secures a contract for fitting up that is a pleasure to him to undertake and gives eminent satisfaction to the customer when done.

When first installing lights in the smaller towns and villages, cheap, but not poor work must be done to get the light introduced, but it should be looked upon as introductory only, and later on an earnest and continued effort be made to weed it all out.

A very common case that arises is that of a customer occupying a shop who is always making trouble about the bills. He has a certain number of lights strewed about without any definite arrangement, one switch to shut off the whole thing when he leaves, no shades, no reflectors, and the shop is half dark when all the lights are on, and if he is on meter and turns off a few to save money he has not light enough to do his work. The result is he is constantly growling himself and making others do the same.

When a case of this kind comes up the manager should go to him and suggest that by rearranging things he can have better satisfaction for less money, talk the matter over and work out a scheme that will put the light just where it is wanted, and add a few switches so that the groups of lights can be readily turned on and off. After the exercise of considerable tact and unlimited patience the customer will begin to be convinced and finally consent to refit. When this is done and the lights placed just where wanted, very possibly lamps of smaller candle power than before can be used on some of them. The result is a well lighted shop, which is a good advertisement for both the customer and company at a somewhat reduced cost to the customer and satisfaction all round.

The fewer lights the customer can install and yet get satisfaction from, the longer hours he will burn them all, and so tend to smooth off the peak of his individual load line. And the cheaper he can do it while still yielding a profit, the better for the company, as he is an advertisement and attracts others. Five customers, each of whom has ten lights and uses them all three or four hours each night, are better than one with fifty lights who uses them all for one hour and then turns off as many as possible.

It must be clearly borne in mind that the candle power of a lamp and the amount of illumination we get from it are two entirely distinct things. The useful illumination is the amount of light reflected back to the eye by the objects on which the light falls, and the quantity and quality of the light so reflected is the important and controlling factor, not the candle power of the source of light. The unit of illumination is the "candle-foot;" that is, a light of one candle power one foot distant from the object to be illumined. This is a comfortable light for reading. The illumination is given by the formula:

$$\frac{\text{Candle power}}{\text{Distance in feet}^2}$$

Thus a 16 candle power lamp 4 feet away gives 1 candle foot of illumination.

The illumination yielded by a certain lamp can be very materially increased by the use of reflectors. The illumination of an object which when below a small light is 1 can be increased to 23 by a paper reflector, to 30 by a white glass one, to 64 by a polished one, and to 260 by a silvered glass hemispherical one. White reflectors throw a very nice soft light and smooth off the edges of the shadows so as to produce a very pleasing effect. In using them it should be remembered that the ordinary law of reflection of light, viz., that the angle of reflection is equal to the angle of incidence does not apply to them; but that the rays of light at whatever angle they may strike the reflector spring off from it in lines perpendicular to its surface. Consequently there should be no attempt at the

*A paper read before the Canadian Electrical Association.

mathematical shapes of optical reflectors, but large flat surfaces must be used. They should always be painted a dead white. The enamelling of reflectors to have a shiny surface is a mistake; they do not give as good an effect to begin with and even the best rapidly lose their gloss.

The following table, due to Dr. Sumpner, gives the reflecting power of various surfaces and shows what a wide variation in the number of lights required for a given illumination may be caused by a change of interior decoration:

White blotting paper	82 per cent.
Ordinary foolscap	70 "
Newspapers	50-70 "
Yellow wall paper	40 "
Blue paper	25 "
Dark brown paper	13 "
Dark chocolate paper	4 "
Plain deal (clean)	40-50 "
Plain deal (dirty)	20 "
Yellow painted wall (clean)	40 "
Yellow painted wall (dirty)	20 "
Black cloth	1.2 "
Black velvet	.4 "

When studying out the lighting of a given place we must consider whether we merely wish for a general sense of the space being nicely or brilliantly lighted, as in a ball room or dining room; or whether particular spots or objects need to be clearly illuminated, as the goods in a shop or the tables in a library.

The most important step to good illumination is to secure to the utmost extent possible that no bright spots or lines of light shall strike the eye. The moment the eye sees the source of light it closes itself up for protection from the direct rays and consequently cannot receive as much of the light reflected from neighboring objects, and therefore does not see them distinctly. The following experiment will illustrate this very clearly: Take a shop with two show windows and hang the lights in one window about the level of the eyes, as is so commonly done, and in the other put the same number of lights in good reflectors close up to the ceiling. Now go across the street and note the result. In the first window the goods on exhibition are fairly well lighted, but it is a discomfort to look at them long and nothing is seen behind them. In the other window the goods are shown up beautifully and you can look at them as long as you wish and at the same time can see right back into the shop and see the goods on the shelves and counters.

In the smaller towns and in many cases in the larger ones the question of getting exactly the best illumination and effect from the lights must be subordinated to that of the cost both of the fitting up and of the current consumed. Also a certain amount of deference must be paid to the ideas of the owners.

Thus in lighting show windows the very best method is to light them from overhead, or from the corners, with lamps in deep and powerful reflectors that will throw the light directly on the goods to be shown and will shield it from everywhere else. If it is necessary for the proprietor to be as economical of light as possible this can hardly be done, as these lamps are useless for general illumination in the shop. In such a case as this clusters under good flat reflectors on the ceiling of the window are best. These show the goods in the windows very nicely, they make the front look much brighter, and at the same time throw a very considerable quantity of light into the front part of the shop where it is most required.

An exceedingly common case is a shop from 20 to 25 feet wide, 40 to 50 feet deep with two show windows, the ceiling being from 10 to 12 feet high, and used for dry goods, tailoring, groceries, etc. A very good arrangement for this is to put a three-light cluster and flat reflector in each window, and three similar three-light clusters down the centre of the shop. The main switch should be placed at a convenient spot near the door by which the employees enter and will of course turn on all the lights. Another switch should then be arranged to turn off the window lights, and another to turn off two lights in each of the clusters in the centre. This will be found to be a most convenient and economical arrangement for the customer, who can proportion his light to the weather and amount of business doing. While the central station man will find that, if the shop is open in the evenings at all, the whole of the lights will be on long enough to cover the maximum demand, or standing charges.

These clusters should not be more than 10' 6" from the floor; were these lights raised to 15 feet the direct light from them would be reduced one-half, calling for double the number to produce the same illumination, but since in this case the reflection from the ceiling and walls would be somewhat increased, probably an increase of 50 per cent. in the number of lights would be sufficient.

Drug stores generally call for special treatment, and the lighting must be made to harmonize with and to show off the fittings. Brackets on the top of the shelving and a handsome electrolier in the centre are generally very acceptable, but as the result desired is more in the way of brilliant effect than of mere illumination for the showing of goods, each case must be studied out to suit the purse and the tastes of the persons concerned.

In the matter of churches the great desideratum is the even distribution of the light, with absence of shadows and the total avoidance of all spots or lines of light that will strike the eye of the congregation, or of the minister, especially during the sermon. The minister, the choir and the organist of course require plenty of light, and it often calls for considerable ingenuity to supply their needs without having a bank of lights most unpleasant to the congregation. If such a group of lights cannot be avoided it should be provided with a switch within convenient reach so that it can be turned out during the sermon. In Anglican and Roman Catholic churches which have chancels separated by an arch from the main body of the building, the lights can often be arranged on this arch so as to be entirely hidden from the congregation and yet throw a very pleasant light on the choir and reading desks.

Lodge rooms should be well lighted, and as they are often finished in very dark colors this is a difficult matter. The lights should be divided into groups controlled by switches, and those at the desks of secretary and treasurer are often wanted to be independent of the others in the room. A dimmer is a valuable addition and should be arranged to control all the lights except those just mentioned. It should be a regular theatre dimmer of ample capacity. Lodges are not as a rule paying customers because their use of the light is irregular and the income per light from them very small. Nevertheless it pays to give a good deal of attention to the fitting up of them, because many get educated to good lighting through them whom it would be difficult or impossible to reach in any other way. It will require a good deal of work to get the first one well done and especially to get the dimmer introduced, but after that it will be comparatively easy.

SOME NOVELTIES IN SWING BRIDGE CONSTRUCTION ON THE TRENT VALLEY CANAL.*

By R. B. Woodworth.†

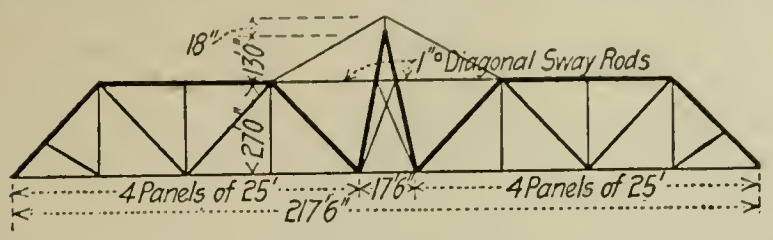
The Trent Valley Canal, now in process of construction by the Dominion of Canada, is projected to extend from Georgian Bay through the province of Ontario to Lake Ontario, and is expected to be of great public value as a waterway. Its construction has naturally demanded numerous high-level and swing bridges.. Several of these were erected during the past year by the Central Bridge & Engineering Co., of Peterborough, Ont., and the purpose of the present paper is to describe certain peculiarities in the construction of the two more important of these, in the design and detail of which the present writer was directly interested.

These were the swing bridges to carry the Grand Trunk Railway over the canal at Nassau, Ont., and the Canadian Pacific Railway over the canal at Ashburnham, Ont. The former had a clear span of 217½ feet c. to c. of end lifts, and the latter a span of 187 feet c. to c. of end lifts. Both were of the same general design, riveted lattice trusses with minor differences due to the different lengths of span and the idiosyncracies of the men who framed the new Canadian tariff. When the material for the long span was ordered angles were most economical; when we came to detail the short span the tariff had made it preferable to use channels. Both were figured for the loadings given under Class II. of the 1896 specifications of the Department of Railways and Canals, viz.: the dead load of the spans themselves, cross ties, rails, etc., at 500 lbs. per lineal foot of span, and a rolling load of two 112-ton locomo-

*From the Engineering News.

†Draughtsman Carnegie Steel Co., Pittsburg, Pa.

tives with a uniform train load of 3,000 lbs. per lineal foot. For the longer span this gives a loading on the turntable, when the bridge is swinging, of about 800,000 lbs. The general style

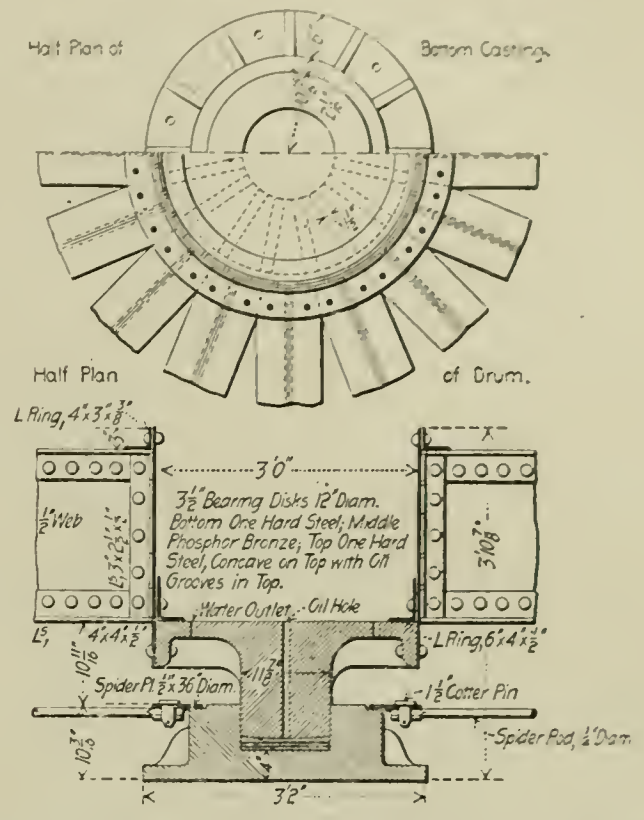


of construction is shown in the diagram, Fig. 1, and need not detain us except to say that all connections were riveted with the exception of the top laterals and the pin connections for the eye-bars and sway-rods connecting the trusses to the central tower. The peculiarities of the construction were three: The turntable centre, the central tower, and the end lifts. The design of the latter is the especial property of W. H. Law, of Toronto, at that time the engineer and manager of the company. The device is based on the use of the toggle-joint, is very simple to construct, and most effective in operation.

Central Tower.—In most swing bridges of ordinary types, whether rim or center bearing, we have to do in the ultimate analysis with beams of complete or partial continuity, and have to take care of shearing stresses transmitted across pivot or drum, and provide special devices to prevent hammering of the truss ends. In the bridge under consideration the rolling load can produce stresses only in the span on which it may be; and the trusses when closed may be figured as simple spans resting on their own supports and completely discontinuous. The turntable is surmounted by a braced tower, Fig. 2, on which rests forged steel links turning on 4 15-16 inch pins, and themselves carrying similar pins to receive the ends of the eye-bars. When the bridge is closed these eye-bars can receive no stress; when the bridge swings, the trusses are simply hung by them to the central tower—a form of construction most simple, effective and economical, easily computed and most practicable in the shop.

It is quite possible, of course, that by some accident or other —a knock from a boat, say—the links at the top of the tower might be drawn over so far to one side as to fail to return to their normal position when the bridge is swung back to its position when closed. To obviate any mishap of this kind, diagonal sway rods 1 inch square are introduced extending from the pins at the hip to the central tower. Here they connect to 2 inch pins which travel in slotted holes 4 inches in length, giving each pin a movement of 1 inch each way from the center. These rods only come into play in the case of accident to the links, and are emergency saieguards and wind braces.

The central portal is double, as shown; one set of bracing acting with the links, the other set giving rigidity to the tower; the whole forming very efficient protection against accidents common to canals as well as against high winds.



Turntable Center.—This was designed for the express purpose of reducing shop cost by keeping the radial girders of full depth throughout their length. The load from the bridge is delivered to the drum by 16 radial girders which receive it from 8 bearing beams—that is, from 8 points of support. The turntable is combined rim and center bearing—and 250,000 lbs. reach the center, while 550,000 lbs. go to the 36 rollers. The center, Fig. 3, of cast-iron or steel, terminates in its own pin, and the form of construction reduces somewhat the amount of power required to turn the bridge; with this additional feature that the necessity of using bolts is entirely done away with. The steel center plate was riveted to the cast-iron center in the shop and the field riveting was then easily done without any special danger to the center.

The whole structure as thus designed merits attention from the manufacturer's standpoint, and its description may be of use in the further perfecting of shop detail, most centers being

an outgrowth from the design of locomotive turntables, while this is an original creation out of hand.

THE EAST WILL BE EAST AND THE WEST BE WEST.

Editor CANADIAN ENGINEER :

Now that the convention held in Montreal last month is a thing of the past, I desire, whilst congratulating those who helped to make it such an immense success as it undoubtedly was, to draw your attention to one cloud, which though only the size of a man's hand at present might, if allowed to spread, assume dimensions great enough to swamp our whole association. I refer to the action at Thursday morning's session with regard to the matter of inspection, when it will be remembered one of the Toronto delegates, first premising that that city was not interested in the matter at all, proposed a committee of four to deal with the matter, consisting of three representatives of electric plant companies (two of which do not do wiring), and one alderman. I have no fault whatever to find with the gentlemen chosen, but I do object to the very class which of all others are interested, i. e., construction men, not being represented. This was pointed out clearly to the mover, and his courteous seconder even asked to add to the amendment such representative, only to be met with the curt rejoinder, "I persist in my motion." Now at the risk of appearing personal, of which I disclaim any intention, I consider the matter is of too great importance to the association to be "mealy mouthed," and therefore have to say (and I am not the only one), that for any member to carry such high handed proceedings, is a state of things the sooner remedied the better. We have bitter experience of West versus East in our own city without wishing to inaugurate it in our association, but I warn the members that if any clique attempts bull-dozing Quebec Province they will find that she is both able and willing to take care of her own interests, electrical and otherwise.

Whilst not altogether agreeing with the main motion I cannot but favorably contrast the fairness of its mover as compared with that of the mover of the amendment, in offering to withdraw his amendment provided a representative of a construction firm was added to the motion.

If the Toronto delegate's intention was to demonstrate that the association was only in the interests of electric plants, he is treading on still more dangerous ground, as the telephone and telegraph representatives will quickly prove to him, or if again, he intends to arrogate to himself the functions of a little pope he will find his following grow beautifully less, so far as this province is concerned, if he interferes in matters in which, admittedly, he has no interest whatever. I would like to ask you, sir, what is the total membership of the Electrical Association? What proportion of the Executive Committee are Ontario members and what Quebec? Apologizing for thus encroaching on your space.

MONTREALER.

Montreal, July 4th, 1898.

ELECTRIC HEATING.

The inventions that have recently been put on the market by the Dominion Electric Heating & Supply Company, Ltd., of Ottawa, mark a distinct advance in electrical heating apparatus. The appliances manufactured by this company relate not only to house and car heating, but to domestic cooking, laundry work, tailoring and clothing manufacturing, hat manufacturing, and other branches of heating where gas and other fuel have hitherto been in use. A representative of The Canadian Engineer called at their works in Sussex street, and saw water boiled in seven minutes in kettles of a size similar to American electric kettles that require 15 to 18 minutes to bring water to the boiling point. The company guarantee to boil water in seven minutes at a voltage of 110. Like efficiency is obtained in their other heating devices. This high efficiency is attained by a new composition which, paradoxical as it may seem, is at once a good radiator and a good insulator, and which moreover will last infinitely longer than the enamel plates and disks hitherto used in electric heating apparatus. In the heaters hitherto in use all depends on the durability of the enamel. Once that becomes cracked or broken the efficiency of the utensil is soon impaired, and finally destroyed. The conductivity of the ordinary enamel disks is from eight to ten as compared with from fifty to fifty-five of the Dominion Heating Company's discs, which can be heated to a degree that would ruin an enamel disc in a few minutes. A test of one of the Dominion Company's discs was made by a continuous use for over a year night and day at a high temperature, and at the end of this time there was no sign of oxidation in the resistance coil. The composition used by the company has a dark and roughened surface and can be applied in such thin coats that there is very little resistance to heat through, which is one of the secrets of its efficiency. Over 2,000 various heaters have been manufactured by this company, and time is rapidly proving their superiority. The catalogue issued by the company describes electric frying pans, sauce pans, pancake griddles, flexible heaters for water bags, tea kettle heaters, chafing dishes, electric tea and coffee pots, broilers or toasters, cake cookers, portable stoves, glue pots, immersion plates for heating baths or wash water, curling tong heaters, tea and coffee urns, bar water urns, milk heaters, plate warmers, foot warmers, flat iron heaters, goose irons, air heaters for bath and other isolated rooms, electric office heaters, library radiators, as well as car heaters, cooking stoves, etc.

Peter McGregor, inventor of this special composition, was born in Glasgow, Scotland, and began to study electrical depositions and japanning while employed in the Milton foundry in that city. He afterwards learned the pottery business and was employed in Moreland's Castle Espie Works, in the county of Down, Ireland. Coming to Canada in 1873 he started the Ottawa Pottery Works in the following year. In 1879 he was awarded the bronze medal presented by the Princess Louis for original designs in pottery.

FRASER VALLEY RECLAMATION.*

BY R. E. PALMER, A.M. CAN. SOC. C.E.

The freshets or floods of the Fraser River, British Columbia, occur as a rule between the latter end of May and the middle of July, caused principally by the melting of the snow upon the mountains. In the reclamation of portions of the delta lands of this valley, from these freshets, the most difficult part of the schemes at present adopted is the satisfactory design and building of the sluice boxes and flood gates. Up to the present time, that portion of the delta reclaimed lies in patches, each portion being protected by itself, and not connected with any other portion. Generally these patches or valleys front on the main river, and are surrounded on all sides, with the exception of the frontage, by high lands, which discharge all their drainage upon the flats. This water finds its way over these flats through sloughs and creeks which discharge into the main river, during the low or ordinary stage of the water, namely, from August to the end of April.

The system of reclamation adopted up to the present day has been that of the construction of dykes or embankments, of different dimensions, along the banks of the river, from high lands to high lands, and of the building in the creeks or sloughs, over which the dykes would pass, of flood gates, and sluice boxes as they are called, which are so constructed as to close during the high water, preventing the river water from backing up the sloughs and flooding the prairies. They are constructed also to open, so soon as the water in the river begins to fall lower than in the sloughs, and drain the prairies, the sloughs during the period when the gates are closed acting as reservoirs, to hold the ordinary drainage from the surrounding hills. In ordinary cases the sloughs have not enough capacity to hold the drainage during the time when the gates are closed, and pumping has to be resorted to, for about a month in the year.

One of the most difficult operations connected with these schemes is the proper designing and construction of these boxes. It is a very difficult matter to keep them tight, and the material in and surrounding these sloughs is such that when once the slightest leakage occurs, under pressure, it is a very short time until the whole box finds its way into the river or up the slough. Again the many and varied kind of sloughs and creeks, the different classes of material through which they pass, varying from gravel and sand to silt and clay, the fact that some discharge into the river where there is a regular rise and fall due to the tide, while others discharge at points where the tide does not reach—(the gates of the former having of necessity to close and open during each tide, while in the

*A paper read before the Canadian Society of Civil Engineers.

latter they need only close during the freshet)—all tend to require very careful examination and much experience before deciding upon the proper design for the gates. In fact, almost every locality requires a gate of a design unique in itself, with some special features differing probably very materially from that required in a locality not half a mile distant. The boxes required for the sloughs located on the river above the effect of the tides are subjected to a very severe test and strain during high water. They are often subjected to a pressure of water due to a head of from 18 to 20 feet and lasting from a month to six weeks. On the other hand, those located on that part of the river affected by tidal waters are relieved twice every day during ebb tide.

The writer gives a description of two of these boxes built by him, one in March, April and May, and the other in August and September, 1896, all being under the same contract. They are built in two sloughs, discharging into the Fraser, through what is known as the Matsqui Prairie. They were designed in 1893 by Fred. J. L. Tytler, C.E., at present supervising engineer for reclaiming lands for the Provincial Government of British Columbia, and were built with several changes under contract by the writer. It may also be mentioned that in each of these sloughs prior to the construction of the ones described, there had been built three different and distinct boxes, each of which had succumbed to the effects of the freshets, and had been torn apart or scoured out, and carried by the flood for long distances over the prairies. One of the present boxes, the only one built at the time, was subjected to a very heavy freshet in July last, the water in the river reaching to a point only 2 feet 11 inches below that reached during the disastrous flood of 1894; but although the work was barely completed when the flood came, and had in consequence barely reached its true bearing, still there was no sign of leakage, or scour, or damage in any one particular. The lumber used in the boxes was all of rough sound cedar, with the exception of the clappers or doors, which were of dressed Douglas fir. The boxes are identical in design, each being 80 feet long by 26 feet wide by 5 feet 8 inches outside measurement, having four openings each 4 feet by 5 feet. They have also each an entrance apron 30 feet x 40 feet, and a discharge apron 60 feet x 40 feet; each contains about 90,000 feet B.M. All spikes were specified to be galvanized.

The most important part of the work is the method of setting the box, and the proper placing of the brush and clay and pickets, and this will be now described. At this point of the Fraser River, there is an ordinary rise and fall of tide, due to the backing up of the river, of about 4½ feet, while during the freshet no difference of rise and fall is perceptible. Both boxes being identical in design it is only necessary to describe the manner of placing one—the most difficult—and located in what is known as No. 3 slough. This slough is about 80 feet wide at the top, and from 25 to 30 feet deep, with water at the time of construction about 10 to 16 feet deep. It drains a large portion of the prairie, besides receiving a large creek from the surrounding hills, and as the weather was very wet at the time, it was necessary for it or the off-take ditch to carry away a large amount of water. The banks of the slough sloped at about ¾ to 1 and were interwoven with roots, and gave signs of sliding from adjacent springs and seepage of water. The method devised and afterwards adopted for placing the box was to build a temporary dam a short distance above the site of the box, another a short distance below the site, excavate an off-take ditch, and having pumped out the portion of the slough between the dams, to commence operations. The off-take ditch was excavated through fairly good clay, being about 12 feet wide at the bottom, with side slopes of about 1 to 1, and varying in depth from 4 to 14 feet. In constructing the upper dam a crib of logs was first built across, notched down and securely drift-bolted together, the logs on the upper side having a batter of about 6 inches to the foot. Along the upper side were driven sheet piles, consisting of 3 and 4 inches plank which penetrated from 4 to 8 feet into the bottom, but on account of the presence of many sunken logs and stumps, it was impossible to get all the plank down to a proper bearing, but they were intended merely to hold the brush and earth, afterwards conveyed in, from being swept down by the current so soon as it was deposited.

At first it was considered practicable to commence this sheet piling at one side, and continue along, finishing at the other, but it was found that the banks were of such a treacherous nature, that the increased current due to the narrowing of the channel, would scour away the banks more quickly than the sheet piles could be driven, and thus destroy the location of the box. It was then decided to commence at both ends, make them thoroughly secure, and work toward the centre. This was done, the sheet piling from each side being closely followed by laborers dumping earth to form an enbankment on the upper side of the crib, keeping plenty of brush on the outside, to prevent the earth being scoured away by the current. After having proceeded thus toward the centre, and when the current became too strong, due to the narrow opening to hold the earth from being washed oway, the gap in the sheet piling was closed, and the backing deposited as soon as possible. But the material in the bottom of the slough was of such a treacherous nature, that no sooner had the water on the upper side begun to rise on the piling than it broke through underneath, the water following the piles down, where it encountered a coarse, red sand, which was soon scoured out, and in a very short time an open channel was made underneath the piling. Sacks were immediately obtained and filled with earth (about 1,200 of them), and these dumped into the channel or hole with loose hay and earth, finally held the current until a large earth embankment was built across. No more trouble was afterwards encountered, although it was subjected at one time to a pressure due to a 27-foot head. The lower dam was built in much the same way, but with less difficulty, there being only a 4 foot tide to contend against. The specifications required all ooze, logs, sticks or perishable matter to be removed from the bottom of the slough, between the two dams, to a maximum depth of 6 feet below the bottom of the box, in order to secure a proper foundation on which to lay the brush and clay. Should the material below that be soft and mushy, then wild hay was to be tramped in below that again, until a firm bed was obtained. But it was to be left to the judgment of the engineer as to how deep up to the six feet the excavation was to be made.

After having pumped out the location—a centrifugal pump with a 4 inch discharge having been used with a maximum lift of about 15 feet—the bottom of the slough was carefully examined and the material tested. The first 2 feet or thereabouts consisted of ooze, slime, brush, logs, stumps and every imaginable kind of worthless matter. Beneath this for from 4 to 6 feet was a bed of silt, of a bluish color, containing minute particles of mica, and very gritty to the touch, but the particles of sand being fine. This when left in its natural bed, and not disturbed, is impervious to water, but once it is moved and displaced, and exposed to the action of water under pressure, it becomes a veritable quicksand. Beneath this was a bed of fairly coarse, red sand. After having made this examination, the cause of the former boxes having been scoured out was apparent to the writer. They had been constructed in the form of coffer-dams built by driving rows of sheet piles braced to ordinary piles, and filling the intervening space with earth or clay. These piles have penetrated this bluish silt, and were driven into the red sand. When the water acquired the necessary head on the outside, after the closing of the gates, it followed down the piles through the silt, into the sand and up again on the other side. The intervening earth was soon washed out, and with it the bottom of the piles, until a channel was formed underneath, and very little time elapsed before the whole structure was scoured out. After having been enlightened as to the nature of the bottom, it was decided to lay the foundation upon this bed of bluish silt, without disturbing it more than necessary. This was done after all the decayed material—logs, ooze, etc.—had been removed from the bottom, and all roots, slides and loose material cleaned off the sides of the banks, and proper slopes of about 1½ to 1 excavated from them. The foundation under the box proper was built up of clay and brush, that under each apron of rip-rap. The specifications for the clay read as follows: "To be of first-class quality, and when kneaded stiff into a pyramid of an inch or so in height, and immersed in water, will remain intact for 24 hours without crumbling. The brush was to be of green bushy fir or cedar trees, of young growth, not more than 15 feet in length, when the stem is cut close to the head, which it shall be, or limbs similar in character." The separate limbs were afterwards practically excluded, and bush allowed much longer than specified, which served the purpose better. The first intention of the writer was to obtain the clay from a bed about a mile up the slough, above the site of the box; but after

the temporary dams had been built, a great quantity of rain fell, and as the off-take never was intended to carry off all the drainage, the water backed up, so that the clay could not be reached. Another bed of blue clay of excellent quality was then located on the river bank, about two miles below the mouth of the slough, and was conveyed by steamer and scows at a heavy expense.

The foundation was laid as follows: A bed of this clay was deposited on the bottom of the slough about 2 feet in thickness, and 80 feet in length, that is, under the site for the box proper. This was laid in layers a few inches in thickness, carefully spread and levelled, and well tramped and pounded down. On the top of this was laid a row of brush with butts to the end. These small trees were laid close together longitudinally, from one side of the slough to the other, and at one end of the foundation. The branches standing up were "nicked" in order to let them lie close. After the first row was laid, another was placed on top partially covering the first layer, similar to shingling a roof, butts all lying out in the same way as number one row. Then another row was laid in a similar manner, until the layer of clay below (80 feet in length) was covered for about two-thirds the distance from one end, or between 50 or 60 feet. After this had been completed, a layer of clay was laid on top from 1½ to 2 feet in thickness, covering the whole foundation. This was thoroughly compacted, and tramped down with horses and then levelled up. Upon the top of this clay was laid another layer of brush similar to the lower layer, but this time commencing at the opposite end of the foundation butts out, and extending for about two-thirds of the way towards the first end, and thus overlapping a portion of the first layer of brush, but care being taken that there was a good layer of clay between, so that the brush in no instance would be continuous through the entire length of the foundation. Upon the top of this was laid another layer of clay similar to the previous layer and so on, until the proper height was obtained to lay the box. When the foundation reached the required height, it was carefully levelled off and made ready for the box. The lower planks of the box floor (5 x 12 x 26 feet) were then laid close together, each one being levelled up and pounded down with a heavy pounder, until it lay on an even bed throughout, in contact with the clay. Upon the top of this floor was built the box as shown on the plan.

From the box to each bank of the slough was laid clay and brush in a similar manner to that in the foundation, care being taken that in no case should the brush extend in a continuous layer right through the embankment, or that it should touch the sides of the box. The clay was laid in thin layers and thoroughly tramped and pounded down, especially close to the box, and also carefully knitted into the banks on each side by key walls. A brush and clay embankment laid in this manner was carried up on each side and on the top of the box, until the top of the banks of the slough were reached, with the exception that, after the top of the box level was reached, the slopes on each end were carried up by driving split cedar pickets about 3 inches in diameter and 6 inches apart, 4 feet into the embankment—each row being 1 foot higher than the preceding one, and 1 foot nearer the centre of the box, thus making a slope of 1 to 1 at the ends. Behind, or inside each row of pickets, was laid "heading brush" or brush laid transversely with the box to keep the clay in place. From the top of the bank of the slough, a dyke of ordinary earth-work was built to the height of the river dyke, about two feet above maximum high water. The aprons were built as shown on the plan, the walls flaring out from the ends of the box to the end of the apron, and rip-rap being hand laid outside of the walls upon the floor, to load it down. From the rip-rap walls to the banks, the slopes were built of rough brush and ordinary earth, laid in a similar manner to the clay and brush.

The gates or clappers used on the box, are of the "top hung" pattern. A difference of opinion seems to exist among the engineers of this district, as to advantages derived from that style over the "side hung" gate. The trouble experienced with the gates on this box was as follows: when the freshet first begins to come, the river only rises a few inches in 24 hours, and, according to the state of the weather, may in its steady rise exceed 6 to 12 inches in one day. Consequently, the gates not being hung perpendicularly, but when closed have a batter of about 1 inch in 12—the water keeps running in underneath the clapper, filling the slough inside, as quickly or nearly so, as the river rises outside, and the clapper to all intents and purposes floats on the stream, there being practically no pressure against it, at least not enough to close it. Weights were attached to the bottom of the clapper which assisted materially in closing them. In the case where the water rises rapidly outside, as in tidal waters, no trouble is encountered, for once it begins to rise, a head very rapidly forms, and the gates will close with a sound as of the discharge of a cannon. Another disadvantage of the "top hung" gate is this: when the slough is discharging, the water inside as a rule is very slightly higher than the falling water outside. Also there are always more or less branches of fallen trees, sticks, pieces of logs, etc., being carried out through the boxes. These must necessarily pass underneath the slightly opened clappers, and in many cases are caught between the floor of the box and the bottom of the gate. Then when the tide changes, and the water turns to flow back into the slough, the debris prevents the particular gate from closing. Well designed grillages both above and below the gates ward off much of the debris, but notwithstanding this it is impossible to keep some branches, fence rails, etc., from passing through. In the "side-hung" gates, less trouble is encountered from this. Here the gates are hung in pairs, closing at the centre of the openings, the debris can then float upon the top of the water, and not being dragged along the bottom of the box, has only the two edges of the gates to encounter, and the gates being evenly balanced, will open enough to allow the debris to pass through. This difficulty of course is only encountered when the head on either side is small, and the gates in consequence are very slightly opened. In "side hung" gates there is a slight disadvantage in that it is very difficult to prevent the gates from sagging through length of time, which prevents them from closing tightly. They must be well designed with very heavy and strong hinges.

In many of these boxes on the Fraser, the gates are hung on the outside of the box, and have an advantage that they are more easily reached should anything prevent their closing during high water.

These gates cost practically $10,000 each.

SEWAGE DISPOSAL.

Editor CANADIAN ENGINEER.

My attention has been drawn to a letter signed "Expert," which appears on pages 47 and 48 of The Canadian Engineer of June, 1898, containing mis-statements and inaccuracies with respect to the International system of sewage purification, which for ten years has been in this country so successfully used, and adopted in preference to all other methods, and is now being introduced into Canada and America by Mr. J. McDougall. It is evident that "Expert," who prefers to make his assertions anonymously, is not master of the subject on which he writes. His statement that the International Company has changed its filtering process from a continuous flow to an intermittent system, "thereby purifying the sewage by bacteria, which require atmospheric air regularly at short periods," is not correct, as the International Company has always recommended, and was the first to introduce, the now accepted principle that filter beds must be worked on an aerating system in order to ensure the best results. At the present time, by means of valuable patented improvements, we are able to aerate filters every few minutes, and at the same time filter at a much greater speed than any other process, and obtain a far higher degree of purity. "Expert" also makes some rash and totally incorrect statements as regards what he calls "Intricate sludge machinery." The sludge removal apparatus used in the International process is of the most simple and efficient kind, effecting great economy in the construction of sewage works, as its use does away with the necessity of large areas of tanks. The apparatus is used by the British Government, and at a great number of sewage works in this country, and its adoption is rapidly extending, which fact is proof of its success. "Expert" also says the precipitant Ferozone is a "heavy constant and useless expense," and that coal screenings are far superior to Polarite—(the filtering material of the International process). These assertions are so wholly incorrect that it is difficult to understand how "Expert" came to make them unless he wishes wilfully to mislead. As regards the cost of Ferozone,

with modern plant and machinery and with a dilute sewage such as met with in American and Canadian towns, chemicals may be dispensed with altogether, there being sufficient dissolved oxygen in a weak sewage to effect the necessary treatment in the sewage tanks, previous to the final purification through Polarite beds. "Expert" rashly says, "Coal screenings are far more efficient and lasting when used as a filtrate, standing ahead of every other material, except charcoal made from wood or town's garbage." The only advocates of charcoal made from town's garbage are those interested in what was known in England some years ago as the Jagger & Turley system of carbonized refuse, which was tried at a little place called Baildon, the results being given in a paper read by W. Naylor, Esq., F.C.S., chief engineer inspector, Ribble Conservancy Board, and published in The Journal of the Society of Chemical Industry, 30th April, 1894; the following is an extract, and will show the utter absurdity of attempting to deal with sewage by such a system:

"An impression has long been abroad among the local board 'Practical men' that coke is the proper thing through which to filter sewage. Reason and figures are of no avail with a sewerage chairman, who has set his mind on coke. It is an old established institution, handed down from father to son, and will die hard, but die it must, for (as shown by the Nelson figures, Nos. 32 and 33) it has no effect on dissolved organic matter at ordinary filter depths and rates of filtration. This coke, however, was pulled out and burnt during a recent coal famine, doing more good on that particular occasion than it ever did before. Its ghost, however, is now on exhibition at Baildon in the form of a 'Carbon' filter (so-called). Ash pit and privy refuse is here burnt, carbonized, it is claimed, and a filter made of the resulting ash. This forms a sand filter, but that is all, and if of sufficient area would perhaps in time form a nitrification bed. This is a process which at once appeals to the minds and pockets of local boards. No precipitants! No expensive filters! Refuse disposed of! No pollution! The impossibility, however, of its application on a large scale must be apparent at once to any but an outsider. The sewage treated at Baildon by this process is initially very weak. Its effect upon that is a mere screening effect, as shown by the results numbered 34 to 37."*

TABLE OF RESULTS.

No. of sample.	Description of sample.	Taken by	Date	Examined by	Part per 10.000 albumenoid ammonia.
32	Nelson effluent before coke beds	Author	8th Aug., '92	Author	2.0
33	do. after	"	"	"	2.0
34	Baildon raw sewage	"	17th Jan.,'94	"	0.345
35	" tank effluent	"	"	"	0.330
36	" filter	"	"	"	0.150
37	" clear sewage	"	"	"	0.130

It is evident that your correspondent, who styles himself an "Expert," is woefully ignorant, not only of the science of sewage treatment, but of what has recently taken place as regards the system he indirectly advocates, viz., carbonized town garbage, which after trial had to be abandoned at the town of Alton, Hampshire, England. Is not "Expert" connected with this carbonized garbage process. Otherwise his unjustifiable attack on the successful International system cannot be understood. Polarite filters are vastly cheaper than any other form owing to the powerful purifying powers of Polarite, which enables a high rate of filtration to be maintained and an effluent of a much greater degree of purity obtained than by any other system. The best proof of this is the number of places at which Polarite filters are in operation. Her Majesty's Government would not use Polarite in England and send it to all parts of the world for purification purposes, could equal results be obtained by coal screenings, coke or similar substances, which when tried, even on a small and closely watched experimental scale, are found after a short time to choke up and become useless, even when worked at so slow a rate of filtration as to render them enormously costly and altogether prohibitive. Polarite filters on the contrary are most economical and their efficiency is shown by the following, which is the opinion of Major Tulloch, C.B., R.E., late engineer in chief to the local government board, on the Chorley Corporation Sewage Works, where the International Ferozone and Polarite process has been in most successful operation for several years:—

"I am highly pleased with what I have seen. The works are excellently managed and looked after, and reflect the greatest credit on the town council. The effluent from the depositing tanks is among the very best I have seen, almost perfectly clear, and with only a faint smell, while that from the filters is as clear as spring water and perfectly inodorous. These works I consider to be among the very best in the country. I know of none where better results are produced."

In view of the anonymous attack made on the International system by "Expert," I trust that your Canadian sense of fairness will ensure the fullest publicity to this letter, for the length of which I apologize, and remain, yours obediently,

FRANK CANDY,
General Manager.

109 Victoria Street, Westminster, London, England.
July 8th, 1898.

*Reprinted from the Journal of the Society of Chemical Industry of 30th April, 1894. Being a paper called "Comparative results of some modern systems of Sewage Treatment," by W. Naylor, F.C.S., Chief Engineering Inspector to the Ribble Conservancy.

GARBAGE DESTRUCTORS.

Editor CANADIAN ENGINEER:

Our attention has been drawn to a letter signed "Expert" in your June issue, and this gentleman mentions the name of our Mr. Warner and the Patent Refuse Destructor, which we manufacture, and we think it necessary to make some comment upon the matter. It is evident to us that this expert is a very dark horse, as in the first place he does not acknowledge his name, and in the second place, he does not know what he is talking about. If he would give his name, facts and figures it could be handled in a proper engineering manner, but, it may be as well to mention that we manufacture several kinds of destructors, both with forced draught, by steam and air blast and with chimney draught, that we are up to the most recent destructors as regards high temperature, cost of refuse treatment and the amount of steam produced, and as some proof of our statement we enclose a reprint from a recent English newspaper showing that after full investigation our patent destructor has been accepted at the city of Bath, the city of Sheffield, and the town of Plymouth. We have since been informed that the town of Hartlepool has passed our scheme for a destructor of 6 cells, and we are at the present time building destructors in different parts of the country and abroad, consisting of upwards of 150 cells; this, we think, is practical proof that our schemes are not so old-fashioned as made out by "Expert." We can say quite as much with regard to the treatment of sewage as we are at the present time supplying a large number of the most important schemes, and carried out under the most eminent engineers including J. Mansergh, Esq., of Westminster; W. Santo Crimp, Esq., T. de Courcy Meade, Esq., Mr. Leiley, Messrs. Pollard & Tingle, of Westminster, and many other borough engineers. In conclusion we can only say we think "Expert" will have to be a student for many years before he arrives at a possible chance of being a professional man, let alone an expert in matters he is talking about. Yours truly.

GODDARD, MASSEY & WARNER.

Nottingham, Eng., July 15th.

SANITARY PLUMBING.

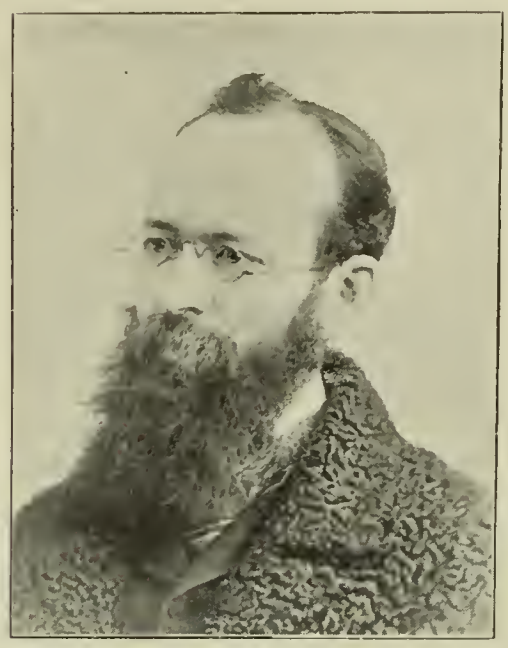
Editor CANADIAN ENGINEER.

I have read with much pleasure W. M. Watson's article on the sanitary experiments at Cologne, and since reading it I have been able to prove the accuracy of the statement that sewage falling vertically through a soil pipe carries down with it several times its own volume of atmospheric air into the main sewer, which is a very important thing and tends to keep the sewers fresh and odorless. I have worked in three of the largest cities in England as a journeyman plumber, where interception traps on private drains or on drains serving rain water leaders were unknown. No more was sewer gas known to enter dwellings or pollute the streets in such quantities as to be injurious or noticeable. I have also worked in Toronto where traps are in general use for such purposes, and when doing repairing work I have found many chokes, and several buildings with the soil under the basement floors completely saturated with the liquid from excrement, which is a mishap that never occurred in any of the towns in which I worked in

England, where sound drains are used. The article has given valuable pointers to thinking plumbers and unbiased citizens who wish to secure the healthiest methods of erecting sanitary appliances. Truly yours, E. A.

Napanee, July 25th, 1898.

WILLIAM HENRY LYNCH.



William Henry Lynch was born at Danville, Que., July 25th, 1847. In his youth he worked as a telegraph operator and was afterwards manager of the old Danville school-slate quarry. When the quarry closed down though the lowering of prices, brought about by American competition, Mr. Lynch turned his attention to the dairy question. Under a strong conviction of the great future before the dairy interests of Canada, and the special suitability of the climate and soil of this country for this branch of agriculture Mr. Lynch began an agitation throughout the country for a reform in the methods then in vogue. From 1881 to 1889 he spent most of his time and money in efforts to arouse the attention of the farmers to the great opportunities before them in the manufacture of butter and cheese for export. He applied himself so intensely to this labor of love that he soon became one of the foremost authorities on dairying. His work attracted the attention of the late Prof. Arnold, of Rochester, who invited him there to carry on experiments in the treatment of milk and the manufacture of butter, and who returned the obligation by coming to Canada to testify to Mr. Lynch's great work in the interests of the Canadian farmer. During this time Mr. Lynch became the author of a book on "Scientific Butter Making," the value of which was manifest by its purchase by the Ontario Government for general distribution among the Ontario farmers. Among the direct results of this work was the establishment of a government creamery, and the incorporation of dairy work as a special department of the Agricultural College at Guelph. "Scientific Butter Making" was followed by "Butter and Cheese," of which 70,000 copies were issued in English and French. The edition was exhausted within a year, and this led to a larger work entitled "Scientific Dairy Practice," which is considered to-day the best hand-book ever issued on this subject, and of which 100,000 copies were printed. During these years Mr. Lynch delivered hundreds of public lectures to farmer's and dairymen's associations, besides addresses to various Boards of Trade throughout Canada. These were delivered without charge and in most cases without even compensation for his traveling expenses, his great work being carried on simply out of conviction of the importance of the subject to the country. That Mr. Lynch looked into the future with a prescient eye is very evident, when we consider the enormous development of the dairy exports of Canada. In 1886 the exports of Canadian cheese amounted to $6,754,620, and of butter $832,355. In 1897 the exports of Canadian cheese amounted to 164,220,699 lbs., valued at $14,676,239, and of butter to $2,089,173. To see what was being accomplished by other countries, Mr. Lynch made a tour at his own expense through Great Britain, Denmark, Norway, Sweden, Holland and Germany, and gave the results of his knowledge to the public in a series of interesting letters, written also without charge, to the leading Canadian papers. He had all along urged federal action by the Canadian Government to promote the export of dairy products, and closed his letters by a call to Canadian dairymen to meet in a convention at Ottawa. The immediate outcome of this convention was the appointment of a Dominion dairy commissioner, and the organization of the governmental machinery, under which our exports of dairy products have since increased with such remarkable strides. Mr. Lynch could have had the appointment of dairy commissioner, but it is in keeping with his character that he declined to reap to his own personal advantage where he had sown so generously. When it is known that he also declined a like appointment offered to him by a foreign government, simply because he did not wish to educate a foreign nation to compete with Canada, and when it is realized that his education of the Canadian farmers has meant millions of dollars in the pockets of the Canadian people, William Henry Lynch may well be enrolled among the Canadian patriots, whose names should pass into history. He was one of the founders of the Canadian Dairyman (the first paper in this country exclusively devoted to dairying), which was afterwards merged into the Rural Canadian. For some years past Mr. Lynch has devoted much attention to mining, being among the first to realize the importance of the developments in British Columbia. He made some suggestions for the improvement of the B.C. mining laws, which, had they been acted on, would have prevented some of the abuses that now exist there.

Mr. Lynch has now been entrusted by the Minister of the Interior with a commission to make a special study of the local condition of the Canadian Yukon district, particularly as to the mining regulations, and to report to Ottawa. Being an original thinker, as well as a man of high ideals, he is not likely to be tied down by precedent, and we may expect that his investigations will result in a code of mining regulations, which while conserving the public interests will give to the honest miner the fullest security, and make the Canadian Yukon a model mining region.

THE CANADIAN MUTUAL AID ASSOCIATION OF MECHANCIAL ENGINEERS OF THE PROVINCE OF QUEBEC.

This association has sent out the following circular to manufacturers: "With a view to securing to manufacturers the advantage of obtaining experienced persons to take charge of steam plants, the mechanical engineers have formed an association which will accept as members only those who are licensed, and firemen who have a thorough knowledge. This association deserves much encouragement because it makes continually a special study of all questions relating to steam machinery, both as to economy and safety. It has also for its aim the mutual aid of its members in case of sickness, and differs from many other societies in that it does not interfere in any way with salaries. Having been founded as much in the interests of the proprietors of steam machinery as of the mechanical engineers themselves, they count on those interested in carrying out these two nobler aims. The president of the association will be most happy to reply to correspondence from engineers and firemen, and will furnish either by letter or personally any information having reference to steam machinery." The circular is signed by Ephrem F. Valiquet, 106 Bourget Street, the president of the association, and is dated from The Mechanical Engineers' Rooms, 392 Lagauchetiere Street, Montreal.

—Bond & Smith, architects, Temple Building, Toronto, are calling for tenders for the reconstruction of a residence on Lowther avenue, Toronto.

—An interesting test has just been completed by James Lang at the power house of the Toronto Railway Co with a view to getting at the actual results of a mechanical stoker as compared with hand firing. The test was made on an improved Jones underfeed mechanical stoker for three days, resulting in a saving of fuel of 15.2 per cent., or an increased evaporation for equal fuel of 17.93 per cent. Minute details of the test are being printed by the General Engineering Co. of Ontario, Canada Life building, Toronto, who will forward the report to those interested in the subject.

"STERLING" HACK SAWS.

Sterling.

Every good mechanic is interested in learning of any new line that will prove to be a labor saver in his work, and the "Sterling" Hack Saw Blade, which has acquired great popularity in the United States is now being freely sold throughout Canada, and used in a large number of the best machine shops. The cost of these blades is less than the value of time spent in filing the old-fashioned blades, which were not tempered. The teeth of these saws are made with a file temper so as to cut through the hardest tool steel, and can be bought at a price so low that it does not pay to waste time in filing saws as had to be done before the tempering of hack saws was reduced to a science, as it now is. The efficiency of these saws is shown by the following tests:

I hereby certify that I was present at a test of the "Sterling" hack saw blade in a 12-inch power saw; that it made 28 clean, even cuts off a bar of Jessop's tool steel; in addition it cut 1 piece 6 in.x5-16 in. machinery steel; 1 piece 3¼ in.x5-16 in. machinery steel; 1 piece 2 in.x5-16 in. machinery steel. Having tried every hack saw blade on the market, I consider the "Sterling" hack saw superior to any blade I ever used.

J. F. Chamberlain,
Superintendent Burgess Arms Co.

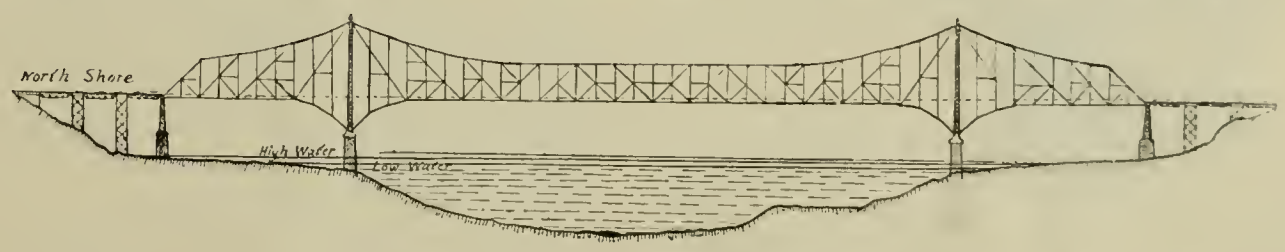
Buffalo, N. Y., March 21st. 1898.

I was present at the Burgess Arms Co.'s plant when the "Sterling" hack saws were being tested in their 12-inch power machine. The test was very satisfactory, cutting 28 to 30 cuts through 1 inch square Jessop's unannealed tool steel; also cutting 1½ in.x5-16 in. machinery steel without breaking. Another saw I used cut through 1 bar 2-inch round, 1 bar 1¼ in.x4 in., 1 bar 2x3 in., 1 bar 3½ in. round, half through, all being unannealed tool steel, saw still unbroken. I consider the "Sterling" equal to any saw in the market. Truly yours,

C. H. Choate,
Tool Maker, Burgess Arms Co.

Buffalo, N. Y., March 21st, 1898.

THE PROPOSED QUEBEC BRIDGE.



Distance between base lines, 2,546.07 feet, from centre to centre of piers, 1,600 feet; between back walls, 3,300 feet; clearance for navigation, 150 feet above high water mark. E. A. Hoar, C. E., is the engineer in charge. Tenders will be called for till Sept. 1st.

FIRES OF THE MONTH.

July 2nd. The Ashbourne flour mill near Bullock's Corners, Wentworth county, Ont.; loss, $10,000; insurance, $8,000.——July 7th. Saw mill owned by Biecher Tingley, Moncton, N.B. ——July 8th. The Mastigouche Lumber Co.'s mills, St. Gabriel de Brandon, Que.; loss, $20,000; insurance, $9,000.——July 10th. Saw mill owned by Daniel Richards, Campbelltown, N. B.; loss, $20,000; insurance about $10,000.——July 11th. The Berlin Brush Co.; partially insured.——July 12th. C. Smith's foundry, Durham, Ont.; loss, $2,500; insurance, $800.——July 13th. The Maritime Sulphite Fibre Co.'s barking mill, Chatham, N. B.; loss, $1,000.——July 15th. The Sherbrooke Iron Works; slightly damaged.——July 17th. The Tilbury, Ont., electric light plant. ——July 20th. N. Cayonette's saw mill, Ste. Moise, Que.; total loss; G. Ross and his son, watchmen, were found burned to death.——July 22nd. The Macdonald Tinware Co.'s factory, Montreal; damages, $15,000.——July 26th. Steamer "D. L. Mather," owned by the Keewatin Lumber Co., burned at Winnipeg; loss, $8,000.—— July 27th. The Linotype Machine Co.'s works, Montreal; loss, $70,000, fully insured.——July 30th. Adam Haines' furniture factory and saw mill, Waterville, Que.; loss about $10,000.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

The ninth annual convention of the Canadian Association of Stationary Engineers will be held in Hamilton, Ont., Aug. 8th. The convention will open on Aug. 8th at 11 o'clock, when the Mayor of Hamilton will welcome the delegates to the city. Committees will be appointed and the convention will then adjourn till 10 o'clock on the 9th, when a business session will be held, followed by an aquatic excursion in the afternoon. In the evening E. G. Barrow, C.E., city engineer of Hamilton, will read a paper on "Sewage Disposal," and J. S. Williams, analyst for J. Winer & Co., will read a paper on "Oils in the Engine Room." On Wednesday, Aug. 10th, business sessions will be held. In the evening the annual banquet will be held at the Waldorf.

GORDON J. HENDERSON.

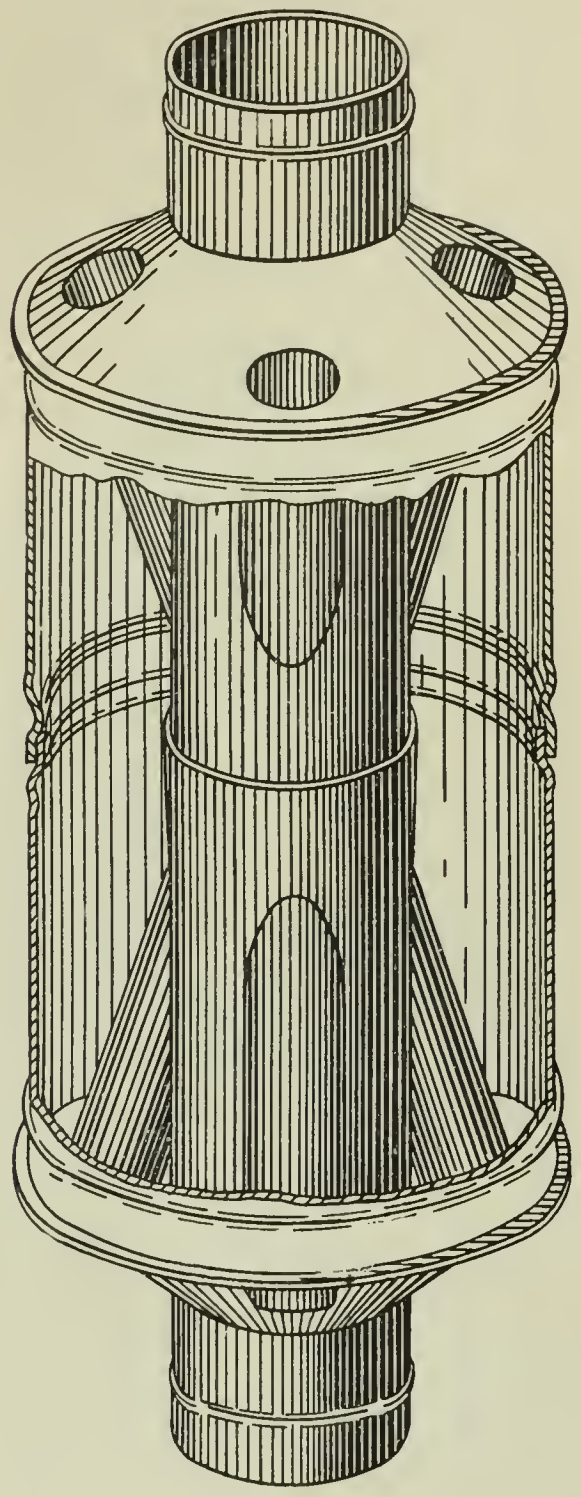
The manager of the Hamilton Electric Light and Power Co., ltd., Gordon J. Henderson, was born in Montreal in 1871, being the son of David H. Henderson, a well-known lumber and timber merchant of that place. Mr. Henderson was six years with his brother, C. W. Henderson, electrical contractor and general supplies, and has been connected with the present company for two years. He has been fortunate in putting this company on a paying basis, as it is a well-known fact that for six years previous to his being appointed manager, it had never paid any dividends. The revenue both from power and incandescent has very materially increased, and expenses all through show a marked decrease. We hope Mr. Henderson will long continue his present successful work. At the recent convention of the Canadian Electrical Association, Montreal, Mr. Henderson was elected a member of the Executive Committee.

THE CHILCOOT HOT AIR HEATING DRUM.

By W. M. Watson.

The coal used in many sections of the country must be imported, which drains the country of its wealth and advances the price of fuel to such an amount that it is necessary to adopt any appliance that will extract an extra amount of heat from the fuel. The majority of hot air furnaces, heating and cooking stoves allow one to two-thirds of the heat from the fire to escape up the chimney unused. The inventor of the Chilcoot Hot Air Heating Drum has clearly shown how much of the formerly wasted heat can now be utilized and made to cause a healthy circulation of warm air in rooms that otherwise would be obliged to have either a hot air pipe or an extra stove to make them comfortable.

Single and double smoke drums have been long in general use and have radiated into rooms quantities of heat in proportion to the exposed surface of the smoke drum, to the distance the drum was placed away from the fire, also the temperature of the fire and the strength of the air draft passing through the fire. It must be borne in mind a coal fire allows its heat to be extracted from it by the iron and brick work that



surrounds the fire, while a fire made of wood is inclined to travel a long way beyond the seat of the fire if allowed to do so, and the smoke drums and pipes of a wood fire will radiate a large share of the heat made in the stove. But no coal fire can burn or be kept alive without some draught of air passing through it which causes the part of the heat of the fire to pass up through the smoke pipes to be discharged into the outside air, unless arrested and radiated into the living rooms by a smoke drum.

It is found that it takes about five times the quantity of heat to raise a volume of water or air ten degrees in temperature more than it does to raise it five degrees, and the difficulty of heating air or water becomes more as the temperature increases. By passing a thin stream of cold water or air over a hot plate at a reasonable rate, about twenty times the number of cubic feet would be heated to a given temperature in a stated time than if the whole quantity of water or air to be heated was collected into one large vessel, and a furnace placed in the centre or under it. Heating the water or air in a thin stream is called heating by circulation. Heating by bulk is called heating by radiation. The fuel that will heat to a temperature of 60 degrees will have to be increased in far greater proportions to raise the heat of the same rooms to 70 degrees. This shows the necessity of using the Chilcoot Hot Air Heating Drum, which combines the two systems of heating in one article. The outside casing or shell radiates quite as much heat as any of the drums formerly used. Then the air of the room is kept in a lively and healthy motion by rapidly passing through an inner drum connected by three collecting and distributing tubes acting similarly to tubes in hot air furnaces. The Chilcoot Hot Air Heater is really a secondary furnace.

The patent rights of this valuable article are for sale by S. J. Robertson, 62 Church Street, Toronto.

LITERARY NOTES.

A very interesting and attractive booklet, "Montreal Homes, Hints to Intending Builders," has been sent us by the author, Arthur J. Cooke, architect, Montreal. It contains a number of illustrations and many suggestions of great value to the intending house owner.

The annual reports of the several departments of the civic government of Halifax, N.S., for 1896-7 have reached us from the office of the city engineer, F. W. W. Doan. A great mass of information, much of it minute in detail, is given. The work of the year in all the departments of the city government is described. The city engineer thus sums up the difficulties of city improvement: "There is a great difference in foremen and the number who can be relied on for cheap work is limited. We are expected to employ men, simply because they are citizens of Halifax, whom no city contractor would have on his work. Such a system is useless and extravagant, if the taxpayer is to get one hundred cents for every dollar expended. The very men that claim that such men are not employed are the first to complain that there is nothing to show for the expenditure. The Works Department is not a Charity Board, and must be run on business principles. Good men can be obtained in Halifax and we should be permitted to select the best. The results during the last three years show what can be done by good men, and the standard set up should be maintained. The accounts of the Clerk of Works tell the story more forcibly than it can be expressed here."

Very few who are engaged actively in the mineral industry are able to find time to read up extensively in technical literature, however much they realize the importance of being fully and accurately informed on all that is going on about them in their own branch of industry. Such busy people will eagerly welcome "The Mineral Industry," each year as it appears from the press, for they find in it a maximum of the information that they need, at a minimum of expense both of money and time. An outline of the table of contents shows the broad field covered by volume VI. This volume contains a review of the production of abrasive materials and their uses, including carborundum, corundum, crushed steel, diatomaceous earth, emery, garnet, grindstones, pumice, quartz crystal, tripoli and whetstones. Special articles on Carborundum, by E. G. Acheson; The Garnet Industry of the United States, by F. C. Hooper, and the Volcanic Ash Deposits of Nebraska, by Erwin H. Barbour. The Mineral Industry, published by the Scientific Publishing Co., 253 Broadway, New York; price, $5.

The "Engineer's Hand Book," just published under the auspices of the Canadian Association of Stationary Engineers, is a handy pocket volume of 286 pages, and contains about 130 pages of tables and information for every day use by steam users, engineers and firemen. Besides a vast amount of data for engineers it contains a short history of the association and its aims. J. G. Robertson, the Executive secretary, assisted by J. J. York, O. E. Granberg, B. A. York and R. A. Ross, E.E., are named as the principal compilers, and well they have done their work It would be hard to find a book in which so much information is packed into so small a compass.

"Friction and Lubrication" is a pamphlet published by the Joseph Dixon Crucible Co., Jersey City, U. S., which describes the excellencies claimed for the preparations of graphite placed on the market by this company. There is also issued by the same company "Graphite as a Lubricant," which treats more extensively of the same subject.

The Ingersoll-Sergeant Drill Co. has issued a new catalogue, No. 32, which illustrates and describes the air compressors built by this company. Separate pamphlets are also issued to describe special installations. One of these describes the plant of the contractor of the Jerome Park Reservoir, New York, who has adopted a compressed air system. The work of excavation involves the removal of over 7,000,000 cubic yards of material, about half of which is rock. The field of operations covers an area of 1½ miles by ¾ of a mile. A compressed

air plant is located at a central point and pipe lines are laid to the points where the work is to be done. At these points are located hoists, pumps, drills and other conveniences for the work, all of which is described in a pamphlet sent out by the company. The Jas. Cooper Mfg. Co., ltd., Montreal, builds this machinery in Canada and Newfoundland.

We have received a very instructive book on "Water and Water Supplies," by John C. Thresh, D. Sc. (London), M.D. (Victoria), Ph. D. (Cambridge), Medical Health Officer to the Essex County Council, Lecturer on Public Health, King's College, London; Editor of the Journal of State Medicine, Hon. Sec. Incorporated Society of Medical Officers of Health, Fellow of the Institute of Chemistry, member of the Society of Public Analysts, etc., etc. The book contains 438 pages, besides a number of illustrations of machinery and appliances, which are of great value. It fully explains and carefully describes the properties and composition of waters, rain and rain water, surface water, subsoil water, natural spring water, deep well water, river water, quality of drinking water, etc. Impure water and its effect upon the health is discussed and the interpretation of water analysis and the pollution of drinking water. The self purification of rivers, the purification of water on a large scale, domestic purification and the softening of hard water are taken up. The quantity of water required for domestic and other purposes, how to select the source of supply wells and how to construct them, pumps of the best kind and pumping machinery, the storage of water, the distribution of water, the law relating to water supplies in Great Britain, are among the other subjects discussed, together with a vast amount of important information necessary for engineers and persons interested in towns or domestic water supplies.

Industrial Notes.

A new public hall will shortly be erected at Millerton, N.B.

The St. Vincent de Paul hospital at Brockville, Ont., will cost $4,000.

The Bushnell Oil Co., Sarnia, Ont., has bought the receiving tanks at Bothwell.

A new hotel to take the place of the burned Clifton House, Niagara Falls, Ont., will probably be erected at a cost of $500,000.

Jno. McGuirl, who was burnt out at Moosomin, Assa., with heavy loss some time ago, will rebuild his wood working factory.

The masons are making good progress with the new buildings of the Deseronto, Ont., Iron Company, and the walls are steadily rising. The carpenters are also at work.

The contract for alterations and additions to the Brantford, Ont., Box Company's works has been let to P. H. Secord. The work is to be completed by 15th September.

The Rathbun Company, Deseronto, Ont., has cleared the ground of the debris caused by the burning of their terra cotta works, preparatory to the erection of new buildings.

D. F. Maxwell, C.E., has been ordered by the St. John City Council to prepare plans for the proposed wharf extension, which are to be filed with the Dominion Government.

The Hamilton Bridge Works, Hamilton, Ont., is very busy and intends to increase its staff. It recently advertised on one day for a stationary engineer, two blacksmiths, four machinists, two punchers and two air riveters.

A. Kellar, Detroit, Mich., wants a free site and a loan of $5,000, in consideration of which he will move the business of the Michigan Heater Co., of Detroit, to Winnipeg. The company is engaged in the manufacture of stoves and furnaces.

J. H. Connor & Son have just completed a new washing machine factory in Jane street, Ottawa. It is three stories high and is operated by two electric motors. The productions of the new factory will be washers and wringers. The damage reported in the firm's late fire was greatly exaggerated, the actual loss being only about $600.

The contract between F. Thompson & Company and Lennoxville, Que., for the building of a system of waterworks for the village of Lennoxville, was signed July 27th, and work was commenced upon the undertaking the next day.

Thos. H. Murphy has purchased from the St. Clair Tunnel Co. all the air locks, rams and fittings used in the construction of the tunnel under the St. Clair. The plant will be used in the contract for the construction of the drainage tunnel in Chicago.

B. D. Hanna, of the Dauphin Railway, has secured some samples of red oxide which were found by a Dauphin man about twenty miles south of Birch Island, in Lake Winnipegosis, Manitoba. If the quality is good the deposits will be of immense value, as there are great quantities of it.

The Shawinigan Water and Power Co. is offering special inducements to manufacturers to locate on the St. Maurice River, Que. Large limits of power may be secured, as this is one of the largest powers in Canada. Information may be had from the company, 1724 Notre Dame Street, Montreal.

Engineer Hibbard, who took soundings for a new bridge at Arnprior, Ont., has sent a report to the town council recommending a two-span bridge with one pier, along with the usual abutments. The cost is estimated to be in the neighborhood of $10,000.

A. Rosseau & Co., Montreal, have been awarded the contract by the city of Quebec for the bridge to replace Bickell's bridge, together with the dam, for the sum of $23.000. The dam or lock is intended to keep the water at a uniform height of twelve feet at low tide around the Victoria Park.

The necessary stock has been subscribed for the proposed scissors factory in Brantford, Ont., occupying a portion of the old Waterous building. The provisional directors are: J. F. Watt, W. R. Turnbull, R. W. Robertson, George Heyd and W. F. Cockshutt.

The annual report of the city engineer of Halifax, N.S., shows that the city water mains have been carefully cleaned during the year, the Kennedy-Keating scraper being used. The engineer also comments on the fact that no progress has been made in the proposed garbage disposal works during the year.

Rhodes, Curry Co., Amherst, N. S., have been awarded the contract for building the Intercolonial Railway pier and sheds in Halifax. The pier will be 600 feet long by 160 feet wide. The plans are completed for the elevator and Hon. W. S. Fielding is said to have promised that the elevator will be open by Dec. 1st.

The committee considering the sewage question in London, Ont., has reported to the city council in favor of the system of the International Sewage Purification Company, Detroit. The plant is to cost $41,300 and the annual expense of operations to be $2,800. Willis Chipman, C.E., is to make a report on the proposed plant.

Mrs. E. J. Sanford, Knoxville, Tennessee, daughter-in-law of Hon. W. E. Sanford, Hamilton, Ont., has given C. Mills, architect, Hamilton, instructions to prepare plans and specifications of a memorial cottage to be erected on the grounds of the Consumptive Sanitarium Association at Gravenhurst, Muskoka.

A license to manufacture in Canada has been granted to the Galena Oil Co., Toronto.

The new iron tank erected by the Edwardsburg, Ont., Starch Co., is nearing completion. It is to contain the water supply of the village, and is forty feet in height, and holds something like 90,000 gallons of water, standing on four legs which are strongly braced. These are sixty-five feet in height, a total height of 105 feet. Two filters are now being installed by the Caledonia Iron Works, Montreal.

The Department of Trade and Commerce has issued a circular calling the attention of manufacturers and others in Canada to the industrial and arts exhibition to be held at Grahamstown, South Africa, from 15th December this year to the 21st January next. Parties wishing to exhibit are asked to make application for space as early as possible, and are notified that arrangements will probably be made for the free transportation of goods to Cape Town. In all likelihood the Government will despatch a vessel direct from Canada to the Cape for the transportation of exhibits, if sufficient are forthcoming to guarantee a full cargo. Parliament, last session, voted an appropriation of $5,000, which can be devoted to this purpose.

Wray & Hawkshaw, Lucan, Ont., have decided to rebuild their flour mill recently destroyed by fire.

The Davis Dry Dock Co., Kingston, Ont., has supplied a compound engine to F. W. Fearman, Hamilton, Ont.

The contract for heating and ventilating the new St. Thomas schools has been given to the Pease Furnace Co., of Toronto.

The Pennsylvania Sanitation Co., Philadelphia, has offered to install a sewerage treatment system in London, Ont., which would treat one million gallons daily at a cost of $1,000 per annum. The bacteria method of purification would be employed.

Dr. Bryce, Toronto, secretary of the Ontario Board of Health, spoke to the town council on a system of sewage for Galt, Ont., recently. Dr. Bryce's address was of considerable length and he urged the people of Galt very strongly to establish a sewage farm at once.

A boiler in Chas. Betts' stave mill, Sycamore (near Coatsworth), Ont., exploded July 15th, instantly killing Jas. Pain, a mill hand, John Rambo, fireman, and fatally injuring Chas. Betts, owner of the mill. The Ontario Government has ordered an investigation to be held.

E. J. Rainboth, C. E., E. S. Leetham, R. G. Code, Ottawa; G. C. Rainboth, Aylmer, Ont.; A. J. Rainboth, Hull, Que., have been incorporated as the Ottawa Suburban Waterworks Company, Limited, to supply gas and water to the villages of Hintonborough and Ottawa East. The capital of the company is $10,000.

On July 12th the Bushnell Oil Co., Ltd., Sarnia, Ont., bought the Petrolia Oil Co., Ltd., Petrolia, Ont., for $4,000, and the Petrolia Crude Oil and Tanking Co., for $17,000, and on the 14th the same company bought the Petrolia Oil Co., Ltd., Sarnia, Ont., for $4,000, and the works of J. R. Minhinnick, London, Ont., for $4,000.

W. H. Croker has completed plans for a large addition to the Tudhope Carriage Company's Works, Orillia, Ont. It will be a four-story building, 50x120 feet. The new building will be used for a warehouse, and will have a floor space of 6,400 square feet, an addition 24x100 feet is also to be made to the wood-working department.

The following contracts have been entered into for the Charlottetown, P. E. I., sewage works: Vitrified pipe, Dodd & Rogers; hard stone, George Battye, Wallace, N. S.; grey stone, John F. Robertson; Portland cement, Dodd & Rogers; brick, Carvel Bros.; pumping engine, the Geo. F. Blake Mfg. Co.; boiler, etc., T. A. McLean.

The new steel bridge over the west branch of the Winnipeg river, Rat Portage, Ont., is now completed, except the approaches, which are to be of earth filling. The construction has been in the hands of T. Jevons, of the Peterborough Bridge Co. It is one of the largest highway bridges in Ontario, the main span being 222 feet in length.

The following tenders were received by the town of Listowell, Ont., for putting in waterworks plant: Clark & Connelly, Toronto, $13,647; McQuillan & Co., Montreal, $14,225; Hill & Gowanlock, $14,899; J. H. McNight, Toronto, $15,173; S. H. Craig, $16,800; J. M. Wallace (piping and trenching only), $6,795. Clark & Connelly were awarded the contract. The firm is installing a waterworks system in Mount Forest, Ont.

The 1898 catalogue of the Sun Bicycle Works shows that the proprietors, G. T. Pendrith & Co., 81 Adelaide street west, Toronto, are steadily gaining popularity with their wheels. "The Sun" wheel and the "Lakeside" are the two special makes of this firm. The latter for a cheap wheel is excellent value, and a Montreal purchaser of one of them informed the writer that her wheel, which cost $55, would pass for an $85 wheel anywhere.

At a special meeting of the Lachine Council, held July 13th, a by-law was adopted granting a bonus of $15,000 to Geo. Barrington & Sons, trunk manufacturers, Montreal, for which the firm will establish their factories in Lachine, Que. The conditions under which the bonus is granted include that the buildings and machinery to be erected to have a value of not less than $25,000, the erection of two factories, the permanent employment of 80 hands, the payment of $25,000 annually in salaries, proper insurance against fire, etc. The bonus will be paid when the factories are in full operation.

The rebuilding of the Truro, N. S., condensed milk and canning factory is progressing rapidly. The new buildings are to be roofed entirely with iron and the contract has been let to an Eastern firm. Roofs of this class are rather uncommon in Nova Scotia.

Incorporation has been applied for by the London Cold Storage and Warehousing Company, Limited, to build and operate a storage warehouse and ice factory in London, Ont. The incorporators are T. H. Smaliman, John Labatt, M. D. Fraser, etc., all of London, Ont. The proposed capital is $75,000.

Railway Matters.

The G. T. R. will construct 250 refrigerator cars for the general service of the system.

A. H. Harris has resigned the position he occupied on the Intercolonial system of railways as traffic manager, and the office itself has been abolished.

Hawkesbury, Ont., has voted a bonus of $7,500 to the Canada Atlantic Railway, to build a siding to accommodate the proposed Riordon pulp mills in that town.

The C. P. R. has under consideration the construction of a branch line of the road to Brantford, Ont. Woodstock being the point at which the connection with the main line will be made.

Neil Keith, railway contractor, is building the C. P. R. branch from Killarney to Hartney, Manitoba. It is understood that Mr. Keith will also build a branch line from Reston to Moose Mountain.

The surveying of a route for the proposed railroad from Amherst, N. S., to the North Shore via Truemanville and Chapman settlement, has been decided upon by the Amherst and Eastern Railway Co.

The Master-in-Ordinary at Osgoode Hall, Toronto, has accepted the tender of Geo. M. Neelon, St. Catherines, Ont., for the purchase of the St. Catherines & Niagara Central Railroad. The bid was $35,000.

The Grand Trunk Railway is renewing the bridges between Island Pond and Montreal. The iron bridge over the Magog and the bridges at Massawippi, Lennoxville, Brompton and Richmond are among the number.

The G. T. R. celebrated the semi-centenary of its Portland line, July 4th. During this time the lines have been extended from 292 miles to 4,186 miles. Fifty years ago the passengers carried numbered 686,924, and in 1897 there were over 8,000,000.

O'Brien & McDonald, Renfrew, Ont., railway contractors, have a contract in Nova Scotia, to build a railway across Hants County between Windsor and Truro. The work which O'Brien & McDonald have consists of twenty miles of grading and sixty miles of ballasting and track laying.

The suggestion that railway employees should be subjected to a severe physical examination and course of technical instructions before being allowed to assist in the operating of trains and switch yards, has been made by the Association of Railway Surgeons in session at Toronto. The association elected as president for the ensuing year, Dr. Bruce L. Riordan, the G. T. R. surgeon at Toronto.

The contract between the city of Quebec and the Great Northern Railway Company has been signed by Mayor Parent and the Hon. P. Garneau, president of the railway company. By this agreement the city invests $200,000 in the stock of the Great Northern and the latter is to give Quebec railway connection with the Booth system, thus making Quebec an exporting port for the Parry Sound traffic.

H. D. Lumsden, C. E., of the Canadian Pacific Railway, who has been engaged at the head of several surveying parties, whose object was to secure a good route for the railway that company contemplates building from a point north of Toronto to Sudbury, Ont., states that a first-class line has been secured, and one where few engineering difficulties are met with. It is pretty well understood that the C. P. R. will enter upon the construction of the road without delay.

The Canadian Pacific will probably extend its Point Fortune branch of the Montreal and Ottawa to Hawkesbury, Ont.

A building 50 feet wide by 100 feet long will shortly be built on the G. T. R. car shops property, London, Ont. It will be for the stores department, and will cost about $5,000 or $6,000.

The Pullman Car Company has completed twenty first-class cars for the Grand Trunk, an order which represents over $100,000. The cars are all of the latest design, and will be a great addition to the Grand Trunk's rolling stock.

The Ontario Public Works Department has received information that the Pembroke Southern Railway, running from Pembroke to Golden Lake, on the Ottawa, Arnprior & Parry Sound Railway, a distance of about 20 miles, will soon be completed. The new line, which crosses the townships of Pembroke, Alice, and Wilberforce, and, after spanning the Bonnecheres river, connects with the O. A. and P. S. Railway, in the township of South Algoma, will, when completed, give Pembroke a competing line with the C. P. R., and will open up a very fair agricultural country. The railway is being constructed by Contractor Poulin, formerly chief engineer for the Parry Sound Colonization Railway.

W. D. Reid, son of R. G. Reid, the Newfoundland railway contractor, when in Montreal recently, stated that they had run a train through from St. John's to Port aux Basque, the terminus on the west coast, in twenty-four hours, the distance being 550 miles. The trial trip was made, however, under most favorable auspices, and the whole distance from east to west was run on schedule time. It is Mr. Reid's intention to establish hotels at different points on the system, so that when the expected influx of tourists, business people and sportsmen sets in, they may be comfortably provided for at whatever section of country they see fit to visit. At present Mr. Reid's steamer, the Bruce, makes two trips a week between Placentia and North Sydney, but with the railway to Port aux Basque the boat will run to that port three times a week, the distance across being made in six hours, and giving Newfoundland a tri-weekly mail to and from the Dominion of Canada. The establishing of separate steamship lines connecting the settlements along Placentia, Trinity and other bays, on south, east and west coasts, with his railway system, is also another important feature in Mr. Reid's vast enterprise in Newfoundland. Plans for seven of these steamers are now being prepared, six for the trade just mentioned, while the other is intended for the Labrador traffic. These vessels will be about 250 tons register, and besides being good freight carriers, will possess superior accommodation for about twenty first-class and from fifty to sixty second-class passengers. They are to be built on the other side of the Atlantic, and while some of them will be placed on their respective routes next spring, the remainder will commence the service a year later.

Marine News.

The steamer "D. L. Mather" was burned to the water's edge at Rat Portage, July 26th. It was insured for $8,000.

The Standard Oil Co. is negotiating with the Canadian Locomotive and Engine Works Co., Kingston, Ont., for the building of a number of steel tank barges to carry oil from the refineries to the distributing points.

The launch of the Dominion Atlantic Railway Company's steamer "Prince Arthur" took place at Hull, England, July 19th. W. R. Campbell, the general manager of the company, was present.

The Richelieu & Ontario Navigation Company will, it is understood, have another boat built at the Bertram yards as soon as the "Toronto" is launched. It will be called the "Kingston," and will be constructed on the same model as the "Toronto," and will cost $250,000.

Lieut. Porter, of the U. S. Cruiser "Yale," has been appointed to command the Rita when she is turned into a transport. He was the officer who commanded the prize crew when she was first captured. Mr. Porter is a son of the Rev. W. H. Porter, Brantford, Ont.

Petersen, Tait & Co. have been notified by the Canadian Government that the fast mail contract must be considered at an end. Petersen's firm will forfeit its deposit of £10,000.

An Ontario charter has been granted to W. J. Brown, Mrs. A. A. Brown, and John McLean, manufacturer, Detroit, U.S.; and T. Mulvey, and J. L. Galloway, Toronto, Ont., as the Georgian Bay Navigation Company, limited, with a capital of $20,000.

T. Eaton's steam yacht the "Wanda" was built from the designs by E. Redway, marine engineer for the Polson Iron Works, Toronto. The dimensions are: Length over all, 55 feet; beam, 3 feet 2 inches; draught, 3 feet 8 inches; displacement, 9 tons; triple expansion engines, 5½, 8½, and 14 inches, with 8 inch stroke; boiler, improved Yarrow carrying 200 lbs. pressure: indicated horse-power, 100; estimated speed, 16 miles per hour. The yacht cost $6,000.

Canadian Pacific Navigation Company are arranging for the building of a fast steamer for the route between Victoria and Vancouver, to give a daylight service. The plans are out, but at present the shipbuilding firms of England and Scotland have too much work on hand to undertake the contract, so it may be a considerable time before the work is begun. The new vessel will, it is said, be much larger than the "Charmer," and faster than any steamer now in service on the Pacific coast.

Last fall the United States government put surveyors on the route of the proposed Michigan-Erie canal, and the chief of the party has just made his report, and he says the canal would not be a difficult work to construct. The line would be from Benlow harbor on Lake Michigan to the Maumie River at Toledo. That would reduce the distance from Chicago to Toledo to 101 miles, a saving of over 900 miles over the present route from Chicago to the mouth of the Detroit River by way of Lake Michigan, Straits of Mackinac and Lakes Huron and St. Clair, and a canal to pass vessels of the heaviest tonnage of the lakes would cost about $40,000,000.

As soon as the proposed Montreal harbor improvements are commenced the Richelieu & Ontario Navigation Company's boats will have to take up new quarters. General Manager Gildersleeve has already made the necessary arrangements. The Quebec steamers are to lie where the "Laprairie" berths now, at the front slip below Jacques Cartier wharf, while the "Laprairie," "Cultivateur," "Three Rivers," "Terrebonne," "Berthier," and "Chambly" will rendezvous at the Victoria pier, or in adjacent slips. New sheds will have to be erected for freight.

Electric Flashes.

Street railway construction is being rushed in St. John's, Nfld., under Engineer Massey.

Galt, Ontario, will shortly vote on a by-law to provide for taking over the town's gas and electric lighing plant.

The Napance Electric Light & Water Co. has ordered from the Royal Electric Co. a 35-k.w. two-phase generator and 500 light capacity in transformers.

The by-law to raise $19,500 for waterworks and electric light purposes in Listowell, Ont., was defeated, July 6th, by a majority of 71 votes, on a total vote of 427.

English capitalists have secured a controlling interest in the New Westminster and Burrard Inlet Telephone Company. The lines of this company extend over a considerable area.

The proposed Lanark-Perth electric railway is being revived. The subscribed capital is now said to be sufficient to build the road, and the company undertakes to complete it by April 1st next.

The town of Thorold, Ont., will receive tenders to Aug. 17th for an incandescent lighting plant of 1,500—2,000 lights, alternating current, according to specifications prepared by R. J. Parke, consulting engineer.

The desire for cheaper telephone service has induced the organization of a company in London, Ont., to rival the Bell Co., and give a house service at $18 and office for $25. Several strong local capitalists are interested, including Col. Leys, John Labatt and John Milne.

The Electric Street Railway, Cornwall, Ont., is building a deep water wharf at St. Lawrence Park.

The Jenckes Machine Co., Sherbrooke, Que., has the contract for installing the lighting plant at Granby, Que.

David Spiers, Galt, Ont., has bought a water power, and may install a power plant if satisfactory arrangements can be made.

The Ottawa Electric Railway is putting its employees on a ten-hour day instead of the eleven hours which had caused some friction.

The West Kootenay Power and Light Co. is now delivering 1,000 h.p. in Rossland, B. C., from its generators at Bonnington Falls, B. C., 30 miles away.

Mrs. Wm. S. Dockrill, Montreal, has ceased to do business alone under the name of W. S. Dockrill & Co., and has formed a partnership under the same name, as electrical engineers with Ernest W. Sayer.

McCurdy & Co., of Antigonish, N. S., are enlarging their electrical plant and have a contract to light the streets of the town. A 60-h.p. engine and boiler have been ordered from the Robb Engineering Co., Amherst, N. S.

McCurdy & Co., Antigonish, N. S., are enlarging their electric light plant and have a contract to light the streets of the town. A 60-h.p. engine and boiler has been ordered from the Robb Engineering Company, Amherst, N. S.

At a meeting of the special committee of the Hamilton city council, on civic electric lighting, it was decided to recommend the council to engage Roderick J. Parke, Montreal, consulting electrical engineer, to report on the cost of establishing and operating a civic electric light plant. The council, however, overruled the committee and engaged Percy Domville.

The Niagara Falls Park & River Railway Co., are now running cars every five minutes over the upper steel arch bridge. The first car was run over, July 1st, with Supt. Rothery at the motor. Manager Phillips of the N. F. P. & R. R., and Supt. Dill, of the new bridge, were on board.

The Crow's Nest Pass Coal Company, ltd., Fernie, B. C., has placed an order with the Royal Electric Co. for 2 25-k.w. direct current generators wound for 250 volts, from which is to be operated a trolley-car equipment for drawing coke to the smelters and also mining, hoisting and lighting apparatus.

The London, Ont., Electric Co. is now installing two 160-k.w. direct current power generators, and a 300 k.w. alternator of the revolving field type, from the Canadian General Electric Co. The power generators will be operated by two engines of 250-h.p. each, made by E. Leonard & Sons, of London.

Edward Slade, electrical contractor, Quebec, is putting in a dynamo, and the necessary wiring for the electric lighting of Capt. Bolduc's new steel boat the "Orleans," plying between Quebec and Ste. Petronille. Mr. Slade has got the contract for wiring the SS. "Champion," and also the Beaufort Asylum, 600 lights.

C. E. Shedrick, who manufactures in Canada the apparatus of the Whitney Electrical Co., will again occupy a portion of the Sherbrooke, Que., Gas & Water Co.'s building recently destroyed by fire as soon as it is ready for him. The business, which has been rapidly increasing in volume, will not be injured by the fire to any great extent.

R. A. Bayley, sec.-treas. of the People's Telephone Co., of London, Ont., has written to the Mayor of Hamilton, Ont., requesting that that city do not grant a franchise to any parties for a telephone company without communicating with it. This is in connection with the movement to establish local telephone companies in each town in Ontario in opposition to the Bell monopoly.

H. Alabaster, Gatehouse & Co. publishers, 4 Ludgate Hill, London, E. C., announce that the 1899 edition of the "Universal Electrical Directory" is in course of preparation for its 18th annual issue in January next. Manufacturers and others interested would do well to send in their names at once so as to be included in the forthcoming edition. No charge for such insertion is made.

Some Galt, Ont., people have formed a scheme for the construction of an electric road from New Hamburg to Galt through Haysville, New Dundee, Roseville and Blair.

Paris, Ont., wants to secure C. P. R. connection by building an electric line from Paris to Ayr, Ont. The promoters are asking for no bonus, but simply for the right of way through the municipalities, a distance of seven miles.

A scheme is on foot to connect Brantford, Ont., and Port Dover electrically, a new line being built from Port Dover to Waterford, and the T. H. & B. tracks being used from there to Brantford. The proposed line is to be known as the Brantford & Port Dover Railway.

The poles for the Cataract Power Co. are now all up between Hamilton and Decew's Falls. Four heavy copper wires are strung from Hamilton to Stoney Creek, about one-quarter of the total distance, and the balance will be strung at the rate of two miles a day. The insulators are being tested at an average of 600 per day, and are tested up to 70,000 volts.

Ontario charters of incorporation have been granted to the following companies: "The People's Telephone Company, of St. Thomas, ltd.," with a capital of $60,000, and the following projectors, A. E. Wallace, E. A. Smith, F. M. Griffin, S. Chant, W. H. Murch, D. McLarty, T. W. Duncome, J. Campbell and A. McCrimmon, of St. Thomas, and H. C. Walters and R. H. Evans, of Detroit, and also to the "Electric Cloth Cutter Company of Toronto, ltd.," with a capital stock of $40,000.

Notices are being sent out to the creditors of the Hamilton Electric Light & Power Company, asking them to send in their accounts for settlement, in view of the taking over of the company's business by the Cataract Power Company. This is understood to refer to a bargain by which the Cataract Power Company undertakes to supply power for fifteen years, and will share in the expected increased profits, but the Hamilton Electric Light & Power Company will not be absorbed, but will continue in existence. It is said the bargain also permits the Cataract Power Company to supply power to the city if the latter goes into the electric lighting business.

The Canadian General Electric Company is manufacturing an incandescent lamp called a "night lamp." It has a device by which it can be changed from 16 c.p. to 1 c.p. The transformation from 16 to 1, or from 1 to 16 c.p., is effected by turning a small screw on the side of the lamp. The current consumed by the lamp when burning at one candle power is less than half of that which it requires at 16 candle power. In appearance, the night lamp resembles the ordinary 16 candle lamp with its bulb frosted. The peculiar construction of this lamp which gives it its double nature, consists in dividing the carbon filament into two sections, one of which is switched into circuit when 16 candles are desired, and both sections—one in line with the other—when only one candle is desired. The additional resistance causes the filament to give out less light.

Henry Symons, Q.C., has just returned from England, where he had estimates prepared for the construction of the proposed works of the Welland Power & Supply Canal Company. This project involves the construction of a canal from the Welland River to the brow of the Mountain at Thorold, a distance of 8 miles; the construction at Thorold of a power house, and from Thorold to Lake Ontario, a raceway by which to carry water into the lake. In addition to these different works, estimates were obtained for the construction of a transmission line from Thorold to Toronto by way of Burlington Beach. The estimates obtained by Mr. Symons were prepared by Dr. Hopkinson, F.R.S., one of the leading electricians of Great Britain; Sir Douglas Fox, Edmund Wragge, late of Toronto, and W. C. Unwin. The estimate for the machinery to generate 100,000 horse-power is £125,000; for transmission line to Toronto at a voltage of 10,000 and delivery of 50,000 horse-power, £801,600; for excavation and other work connected with the undertaking, £1,525,062. The total estimate therefore amounts to £2,452,162, or roughly speaking, $12,000,000. If the amount to be delivered in Toronto is reduced to 20,000 horse-power, the project would cost $1,000,000 less. S. Pearson & Son, contractors, state that if the contract could be secured from the cities of Toronto and Hamilton for a considerable quantity of power, for a definite term, there would be little difficulty in raising money for the project by bonds and shares in Great Britain.

Mining Matters.

Mica of very fine quality has been discovered near Arkell, Ont.

A steam plant is being installed on the Atlantic Cable mine, Rossland, B.C., owned by William Caldwell, Toronto.

Rich quartz is reported from the township of Dysart, Haliburton, Ont. It is also stated that beds of sand containing gold exist in the same locality.

Efforts are being made to develop natural gas extensively at Humberstone, Ont., with a view of inducing manufacturers to locate in that neighborhood.

The Summer Mining School maintained at Rat Portage, Ont., by the Ontario Government is conducted this year by J. Watson Bain, B.A., Sc., of the School of Practical Science, Toronto.

The War Eagle mine of Rossland has let a contract to the Wellman & Sevver Co., Cleveland, Ohio, for the construction of a large steel gallows, frame and hoisting apparatus, at a cost of $20,000.

The Donnelly Bros., Kingston, Ont., have purchased all the plant of the Frontenac Oil Company at Fredericksburg. The plant consists of steam engine and boiler, 15,000 feet of 8-inch pipe, drill, derrick and tools.

The Kaladar and Anglesea Gold Mining Company will at once begin the erection of a separating plant on its property at Bridgewater, Ont. The work will be performed under the direction of Dr. Eames, the company's assayist.

A company has been formed in Vancouver, Ont., to dredge for gold in the rivers of the Yukon district. A special pneumatic caisson and air-lock elevator will be used, which it is claimed will make the work of dredging to bed rock easy. H. Abbot, R. G. Tatlow, J. W. Campion, S. O. Richards and Major C. C. Bennet, Vancouver, are interested in the company.

The Harris Sulphur and Copper Company, Glasgow, Scotland, has secured options on several copper mines in Newfoundland, which were secured by an expert sent out to examine them. These properties include the Colchester, Robert's Arm and Sunday Cove mines, all situated on North Dame Bay, as well as a lease of the Silver Cliff mine on Placentia Bay.

R. Prefontaine, M.P., J. R. Fair, Montreal; C. A. Chenevert, Berthierville; A. Brosnan, J. U. Gregory, Quebec; C. King, Sherbrooke; L. F. Morrison, Saint Hyacinthe; C. Nelson, Montreal, and W. de F. Nelson, Saint Paul, U.S.A., have secured a Quebec charter as the Eastern Townships Chrome Iron, Mining and Milling Company, Ltd. Capital, $50,000; headquarters, Montreal.

Archibald Blue, Director of the Bureau of Mines, has received a letter from Prof. W. L. Goodwin, Principal of the Kingston School of Mines, stating that the summer mining at Parry Sound had proven a great success. In all 51 students had attended, and the daily average attendance had been 20. The school at Mattawa had been, he said, even more successful. There 72 students had come, and the average attendance had been 45, and there was no indication of a falling off. The bureau has divided their summer school between the School of Science and the Kingston school, the former taking the district west of Michipicoten and the latter Michipicoten and the territory east.

The officers of the Toronto Smelting Company, Limited, Madoc, Ont., are: James Kendry, M.P., Peterboro, president; J. B. Hay, Toronto, 1st vice-president; F. C. Flannery, Toronto, sec.-treas, and W. A. Hungerford, M.E., Belleville, general manager. Two smelters of five and fifteen tons capacity respectively have been put in for the smelting of ore and the manufacture of mineral wool. Mr. Burton of St. Louis, Mo., has charge of the smelters; Mr. Norman, a gold medalist graduate of the school of mines for the State of Missouri, is in charge of the assay department, and George Lee, of Staffordshire, England, superintends the roasting of arsenical ores.

As showing the extent of the work going on in Rossland at present a western contemporary states, when speaking of the recent driving of a tunnel between the Le Roi and the Black Bear mines: "Only a very few feet of work would be necessary to drive a shaft from the Le Roi's workings to those of the Centre Star, and if this is ever done it would give a continuous underground passage from the Black Bear through the Le Roi into the Centre Star, thence into the Iron Mask and from there to the War Eagle, for the workings of the latter mines are already connected. From the War Eagle it would require only a few feet of work to connect with the Poorman, and as the latter already opens into the Josie, it would thus extend the chain of connecting properties through to the latter mine. The horizontal workings thus connected would measure about three miles in length."

The Cumberland Railway and Coal Co has a contract for 50,000 tons of coal for the I.C.R.

The Grand Calumet Mining Co., Calumet, Que., has made a trial shipment of 250 tons of ore to Belgium.

J. E. Hardman, B.Sc., of Montreal, spent some time in the Whycocomagh district of Cape Breton recently, in the interest of Canadian capitalists.

Wallace Bell, well sinker, St Lawrence street, Montreal, has gone to Newfoundland, where he will help in developing the newly discovered oil regions in the island.

F. H. Drew, Michipicoten, Ont., reports the discovery near Lake Wawa of a vein of copper-bearing ore very much like that in the famous Calumet and Hecla mine, Michigan.

Gold is reported from Chelsea, Molega, Lunenburg county, N.S., and prospectors are said to have cut a large and rich looking lead there, which shows gold very plainly in the outcrop.

The Boston Company developing the oil wells of Lake Ainslie, Cape Breton, are progressing favorably with the work. They have lately received 16,000 feet of wall casing which will be utilized in the work.

W. J. Hopgood, Spring Garden Road, Halifax, N.S., has chartered a small schooner which will carry provisions, implements and mining men necessary to prospect for some time on the coast of Labrador, where traces of gold have been reported.

The Ingersoll-Sergeant Drill Co., New York, has just issued a new air compressor catalogue, No. 32, which illustrates and describes the compressors which are making such a name for themselves on the Canadian market, for which they are manufactured by the Jas. Cooper Mfg. Co., Ltd., Montreal.

The old Bruce Mines, near Thessalon, have been taken over by Lord Douglas, of Hawick, on an option, writes an associate of this gentleman, to the Bureau of Mines. For some time past Lord Douglas has had experts at work on the mine, and their reports have been very encouraging.

E. R. Faribault, of the Geological Survey, Ottawa, is at present at work in Nova Scotia. He will survey Renfrew, South Uniacke, and Mount Uniacke. After these districts are covered, he will remove to Halifax and from there go over Cow Bay, Montague, Lake Catcha and possibly Lawrencetown and Tangier.

A deposit of manganese has been located at New Ross, Lunenburg Co., by Charles Keddy and W. Rafuse, on the property of Peter Benjamin of the above place. It is said that several barrels of the outcrop were sent to New York to be tested, and the reports received are said to give ore values of from $15 to $60 per ton.

The Government has refused to prohibit the exportation of natural gas from Ontario, as requested a few weeks ago by the largest deputation that ever visited Ottawa. The people of Essex asked, failing total prohibition, for a heavy export duty. This, too, has been refused. Permission has been given the American concern—the Interior Construction and Improvement Company—to lay two new conduits from the town of Sandwich to Detroit, and to convey across the border up to three billion feet of gas per annum. This is accompanied by some conditions which may not be enforcible. At the end of three years the company which is now reaching out into Ohio, is to confine its operations to Detroit. It is provided that natural gas must at all times be sold in Canada at ten per cent. lower than the lowest price at which it is sold at any other point, and that the selling price in Canada at any well, or on the highway nearest the well, shall not exceed five cents per thousand feet. The company is forbidden to use artificial means for drawing gas from the wells.

From Sault Ste. Marie Prof. A. P. Coleman, of the Provincial Crown Lands Department, writes his chief, Director Blue, of the Bureau of Mines, as follows: "We have just returned from a ten days' trip down the St. Mary's River, and along the north shore of Lake Huron as far as Thessalon. We visited Garden River, Echo Lake, Bruce Mines and Thessalon, making a survey of the shores and pushing a few miles inland at each place. The more important mines along the shore and inland have been visited, with the exception of the placers near Thessalon, where we found no work is at present going on. We hope to see them later in the summer. The most interesting point was, of course, Bruce Mines. We found the Cleveland Company at work with more than forty men at the quarry of 'trap' or diabase, for the boulevards of that city. Mr. Spence, who is managing the operations at the quarry, says that these roads cost at present $2 per square yard, and that the surface, when complete, is far better than asphalt, not having the slippery character of the latter in rainy weather, and being far more durable. This pavement might be introduced into Toronto for good residence streets."

Considerable interest has been aroused in England over the discovery of corundum in the township of Carlow, Hastings county. Ontario corundum, it will be remembered, is a valuable substitute in the manufacture of abrasive wheels, and is also one of the chief bases of aluminium. In an editorial the London (Eng.) Mining Journal discusses at length the discovery of the mineral in Hastings and speaks about its possibilities as a commercial product. The Journal notes the fact that the deposits have been traced through over seven different townships over an area of about 100 square miles, and goes on to give in detail the circumstances surrounding the discovery of the deposits and its exploration by private parties and agents of the Ontario Government. The Journal then proceeds to say that in the United States and in Europe aluminium is produced chiefly from kaolin and cryolite, which contain a smaller percentage of the finished metal than does corundum. The only known valuable cryolite mine is in Greenland, where mining operations are conducted with much difficulty. In Ontario these corundum deposits are easy of access and may be worked continuously all the year round. As an abrasive material this corundum has already been favorably reported upon by American experts who have examined samples. If it turns out, as seems probable, that the corundum can be smelted economically for the production of aluminium this will give it a value second to none in the mineral resources in Ontario. The tests which have so far been made are merely sufficient to show that successful concentration of the ore is feasible on a large scale. The Mining Journal gives prominence to its editorial and seems to consider the possibilities of the Hastings deposits to be good.

Personal.

T. J. Sabin, contractor, Peterboro, Ont., was drowned in Little Lake, Ont., while fishing.

R. Cullen, snperintendent of the sulphite plant in the Riordon Paper Mills, Merritton, Ont., has gone to Hawkesbury, Ont , to superintend the mills to be established there.

Grant Hall, mechanical foreman of the Intercolonial Railway, Moncton, N.B., received notice of dismissal, to take effect on Aug. 31. His place is to be taken by Fred G. Hunter.

Edward Butler, Government electrician for the Lachine Canal, Montreal, died recently after a three weeks' illness. He was forty-two years old, and leaves a widow and eight children to mourn his death.

Mr. Spencer, formerly an engineer in the employ of the Peninsular and Oriental Steamship Co., running between Bombay and Hong Kong, has located in Galt, and is now employed by the Goldie-McCulloch Co.

James Green, a well-known G.T.R. engineer, died at Stratford July 13th, aged forty-four years. About twenty-three years ago he entered the employ of the G.T.R., and had ever been a faithful and attentive employee.

John Patton, foreman pattern maker in the Truro Foundry and Machine Co.'s works, and one of the oldest employees of the company, lost four fingers from his right hand, owing to it coming in contact with a saw a short time ago.

Andrew Harrison, an employee of the Canada Sugar Refinery &o., Montreal, was killed a short time ago by coming in contact with the transmission wires of the Lachine Rapids Hydraulic and Land Co. while holding on to part of an iron bridge.

Henry Szlapka, engineer and manager of the Hamilton Bridge Works Co., Ltd., Hamilton, Ont., was very successful in the discharge of his duties when on the staff of the New Jersey Steel and Iron Co., Trenton, N.J., where he had charge of the designing department.

Joseph Taylor, formerly secretary of the Michigan Peninsula Car Works, and identified for years with some of the most prominent business interests of Detroit, died July 19th at his summer residence, Taylor Point, Sandwich, Ont. Mr. Taylor was 58 years of age, and was born in England, but had spent the greater part of his life in Detroit. He was formerly for ten years chief assistant to the general manager of the Great Western Railroad.

T. B. Speight, of Speight & Van Nostrand, has been commissioned by the Government to run an exploration line due north from the head waters of Goulais River, following the 84th meridian, to the C.P.R. Railway, a distance of 90 miles. This is a district that is almost wholly unknown. Mr. Speight will be accompanied by a woodranger and a geologist, W. A. Charlton, who will explore the country for a distance of ten miles on either side of the line, and report upon the timber and mineral resources and the agricultural possibilities of the district.

Joseph Middlemas, engineer at the Deaf and Dumb Institute, Belleville, Ont., has been relieved of his duties.

Jos. McGregor, Nanaimo, B.C., has been appointed provincial inspector of metallurgical mines for British Columbia.

George Todd died in Fredericton, N.B., on the 12th ult., at the age of 86 years. He was the originator and manager of Todd's foundry , Woodstock, N.B.

J. N. Young, general manager of the Dominion Construction Company, has removed from Hamilton to Chicago, after a residence in the former city of about nine years.

Leopold Meyer, mining engineer, of California, has moved to Ottawa, Ont , with his family, to live. He has been appointed manager of the Grand Calumet mine, Pontiac county, Que.

Thos. McFarlane, lately chief clerk in the office of the superintendent of motive power of the Grand Trunk Railway, Montreal, died in Brockville, Ont., a short time ago, at his father's home.

Wm. Tye, C.E., formerly of Haysville, Ont., has been appointed chief engineer of the Robson and Boundary Creek Railway at $5,000 a year, and a good bonus if he succeeds in getting it finished on time.

D. McLennan, of the Auditor-General's office, has been appointed astronomical computer to W. F. King, chief astronomer of the Department of the Interior. Mr. McLennan is a graduate of Toronto University.

W. J. Weller has been appointed superintendent of bridges and buildings of the Crow's Nest Pass branch of the Canadian Pacific Railway, with headquarters at Lethbridge, Alberta, in place of R. Balfour, resigned.

W. F. Robertson, New York, who has succeeded W. A. Carlyle as British Columbia minerologist, is a graduate of McGill University, and is very highly recommended by Dr. Dawson, head of the Dominion Geological Survey.

Henry Tandy, of Dunkirk, N.Y., has been appointed superintendent of the Canadian Locomotive and Engine Company, Kingston, Ont., in place of F. J. Leigh. Mr. Tandy was previously connected with the works in Kingston, and is a capable manager.

Thomas A. Harvey, formerly with Moore & Henry, London, Ont., who has recently graduated with the degree of civil engineer from the Rennsselaer Polytechnic Institute, Troy, N.Y., has taken a position in the bridge and construction department of the Pennsylvania Steel Company, Harrisburg, Pa.

J. Murphy, engineer for the Cornwall Electric Street Railway, who has taken a good position in Montreal, was presented by the employees of the railway with a beautiful smoking set as a token of their esteem. The present was accompanied by an appropriate address, which was read by Mr. Taylor, superintendent of the company.

Among the Royal Military College graduates who have recently received good appointments are : Capt. A. H. Van Straubenzie, R.E., who has been appointed to the command of the "M" submarine mining company at Chatham. He is a son of Lieut-Colonel Van Straubenzie, late D.O C., Kingston. Lieut. A. Adams, R E., third-class, first grade superior revenue establishment of Burmah State railways traffic department, has been promoted to second class fourth grade of that establishment. He is a son of Mr. Adams, architect, late of the Kingston penitentiary staff. Captain A. C. Joly de Lotbiniere, C.E., has been appointed assistant instructor, School of Military Engineering, Chatham.

We regret to record the death, in Montreal last month, of Thomas Hartnell Spurrier. Mr. Spurrier was born in Shepherd's Bush, London, England, thirty-seven years ago, and was educated at Spurgeon's College and afterwards at Regent's Park College. His parents intended him for the ministry, but Mr. Spurrier preferred literary and artistic work, and was engaged in painting and newspaper work before coming to Canada. He settled in Montreal five years ago and was engaged by McGill Medical College to do the anatomical painting of that institution. He also contributed some spirited cartoons and sketches for the daily press as well as for THE CANADIAN ENGINEER. He was very popular among the engineers, his sketches of the annual conventions having been much appreciated. A few weeks before his death he had finished the compilation of a book on the "Yukon Region of Canada," which is shortly to be published by a London House. Mr. Spurrier was an agreeable companion and conscientious worker and will be mourned by many friends as well as his family. He leaves a wife and three young children. He had just brought his two eldest children through a severe attack of typhoid fever, which he himself took with fatal result as they were recovering.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports of interest to the metal trade from Great Britain during June and the six months ending June, 1897, 1898:—

	Month of June.		Six months ending June.	
	1897.	1898.	1897.	1898.
Hardware and cutlery	£6,283	£1,675	£31,930	£11,918
Pig iron	1,847	384	2,865	6,157
Bar, etc.	808	1,627	5,013	6,737
Railroad	..	7,845	20,286	14,817
Hoops, sheets, etc.	6,245	5,034	22,690	16,626
Galvanized sheets	3,377	3,187	19,375	24,167
Tin plates	7 981	11,507	88 953	73,475
Cast, wrought, etc., iron	2,369	2,684	17,334	16,342
Old (for re-manufacture)	925	1,571	1,497	3,075
Steel	4,958	3,559	23,438	27,857
Lead	2,806	4,240	7,260	12,290
Tin, unwrought	909	1,698	9,834	10,785
Alkali	3,638	4,273	15,360	21,010
Cement	1,777	1,700	6,555	10,052

FIRE-PROOF BUILDINGS.

BY FRANCIS C. MOORE.

I think it advisable, in an article of this kind, to state, as premises, certain propositions which might be treated as deductions. Some of them are self-evident, and ought to appeal to any practical mind as being truths, rather illustrated than demonstrated by the experience of the past few years. In accordance with this line of treatment, I desire to state by way of premise:

It may be claimed that no construction is "fire-proof," and that even iron and masonry could with propriety be designated as "slow burning." The iron or steel used in a modern building has, in its time, been smelted in a furnace which presented no greater capacity for running metal into pigs than some of our modern buildings, whose interior openings from cellar to roof correspond to the chimney of a furnace, and the front door to its tuyere. If a pyrometer could be adjusted during the progress of a fire it would be found to rise quite as high as in any forge.

Glass windows will not prevent the entrance of flame or heat from a fire in an exposed building. It may seem strange that so obvious a proposition should be thought worth stating, and yet to-day more than 75 per cent. of the "fire-proof" structures of the country have window openings to the extent of from 30 per cent. to 70 per cent. of the superficial area of each enclosing wall without "fire-proof" shutters. Heat from a building across a wide street finds ready entrance through windows, and the several "fire-proof" floors serve only to hold ignitible merchandise in the most favorable form of distribution for ignition and combustion, like a great gridiron, to the full force of a neighboring fire. A recent article on the Pittsburgh fire in The Engineering News aptly expresses this in the following words: "There seems to be some irony in calling buildings 'fire-proof' which opposed hardly anything to a fire from across the street more sturdy than plate glass!"

Openings through floors for stairways or elevators, gas, water, steam pipes, and electric wires, from floor to floor of "fire-proof" buildings tend to the spread of flame like so many flues and should be fire-stopped at each story. This fault is more generally overlooked than any other. Ducts for piping, wiring, etc., should never be of wood.

In view of the fact that it is necessary to cover iron with non-combustible, non-conducting material to prevent its exposure to fire and consequent expansion, and in view of the fact that all ironwork, except cast iron, will rust to the point of danger, it is best to use cast iron for all vertical supports, columns, pillars, etc. It is not advisable, of course, to have floor beams of cast iron (except in the form of Hodgkinson beams thoroughly tested). If a floor beam should give way, however, it might not necessarily wreck the building, whereas if a vital column should give way a collapse of the entire structure might result.

At a convention held some years ago in New York, at which were present a greater number of experts in iron than probably ever met before or since in one room, there was not one who contended that cast iron would rust beyond the harmless incrustation of the thickness of a knife blade, whereas there was not one who did not believe wrought iron would rust to the point of danger; and there was not one who claimed to know whether steel would or not, each admitting that steel had not been sufficiently tested as to rust to warrant a reliable opinion. If it could be relied upon as rust-proof, it would be superior to all other material for "fire-proof" buildings because of its great strength in proportion to weight. The use of steel in construction is growing, because it is cheaper than wrought iron, as lighter weights are used for the same strength, but while supposed to be superior to wrought iron, some of the prevailing impressions with regard to it are erroneous. Defects not possible of detection by tests are liable to exist in its structure. Among the first steel beams brought to the city of New York there were instances in which they were actually broken in two by falling from the level of trucks to the pavement, probably due to their having been rolled when too cold, as steel when rolled below a certain temperature becomes brittle. Better beams are now made. In my opinion, cast iron columns are superior to steel and more reliable. It is not generally known that American cast iron is vastly superior to English cast iron, and will stand a greater strain without breaking. Cast iron, moreover, will not expand under heat to the same extent as wrought iron and steel, which is another fact in its favor.

No bearing column should be placed in such a position that it cannot be uncovered and exposed for examination without danger to the structure. One of the ablest architects in New York makes it a rule to so "fire-proof" his columns that they can be examined at any time by removing the "fire-proofing" to determine whether rust has invaded their capacity to carry their loads. In my judgment, examinations should be made, from time to time, in this way, of all wrought-iron or steel columns, as it may happen that a leaky steam or water pipe has worked serious harm. Such a discovery was accidentally made recently in an important New York building. Numerous newspaper paragraphs appear, from time to time, which claim that metal stripped of its covering of cement has been found exempt from rust, with the paint intact, etc., and the fact is cited as evidence that cement is a preservative of iron and that the danger of rust is over-estimated. It is probable that cement will protect paint for a long time, and, of course, paint, if properly put on, will protect iron while the oil in it lasts. Painting, by the way, should be done with the best quality of linseed oil and without the use of turpentine, benzine, or dryers. It should be thoroughly applied in three coats, with about a gallon to 400 square feet, and the iron should be first thoroughly cleaned of rust and dirt, by picking or other process. Paint is rarely properly applied, however, and even when of the best quality, is a preservative of the metal, as already stated, only so long as the oil in it lasts.

Those who claim to have evidence of the exemption of iron from rust rely, I think it will be found, upon iron which has been under exceptionally favorable conditions, free from dampness, the action of gases, etc., overlooking the fact that a leaking water pipe or steam pipe, or the escape of gases from boiler furnaces will attack iron and gradually but surely consume it. A notable instance of this is the case of the plate girder of the Washington bridge over the Boston and Albany Railroad in Boston, where a quarter-inch plate girder was recently found to be entirely consumed in places from the operation of gases from the locomotives passing below.

It is quite common to have advocates of wrought iron cite railroad bridges and the elevated railroad structures of New York as proof of their claims, but if they will take the trouble to examine these structures, they will discover that in spite of the fact that they are exposed to view, that they can be painted frequently, the evidences of rust are unmistakable, especially about the rivets; and one can well imagine what would be the result in the case of riveted iron members in the skeleton structure of a building where such ironwork is entirely concealed from view, periodical inspections being impossible. Rust is especially liable to be found in the cellars and basements of buildings. The wrought-iron friction brakes of freight elevators in the cellars of stores, for example, are frequently found so consumed with rust as to be easily rubbed to pieces in the hand. Steel rivets are dangerous and they should never be used, unless of a very superior quality, so soft that hammering will not crystallize the material, and yet with sufficient tensile strength

*Extracted from the publications of the British Fire Prevention Committee.

to insure perfect holding qualities. This is difficult to secure. Their use in columns for buildings is objectionable, as they rust badly under certain conditions; columns, therefore, should be without rivets, and the beam-bearing bracket shelf on cast iron columns should be cast in one piece with the column. It is generally supposed, and frequently stated, that there is a great difference between the expansion of iron and masonry by heat. This is not the case. For example, the length of a bar which at 32 degs. is represented by 1, at 212 degs. would be represented as follows:

Cast-iron	1.0011
Wrought iron	1.0012
Cement	1.0014
Granite	1.0007
Marble	1.0011
Sandstone	1.0017
Brick	1.0005½
Fire-brick	1.0005

In the "fire-proof" building of the Western Union Telegraph Company, in New York, some years ago, a heavy brick pier, 7 or 8 feet in diameter, adjoined the wall of the boiler furnaces. The difference in expansion in the brickwork next to this furnace wall as compared with that of the remaining brickwork of the pier was so great as to produce a crushing of the material from top to bottom of the pier for a depth of several inches, and it was found necessary to change the furnace wall and leave an air space between it and the pier.

While the difference in expansion between masonry and iron incorporated with it is less per running foot than is generally supposed, and while the difference in expansion between a cubic foot of iron and that of a cubic foot of masonry would hardly be noticeable, especially if the iron were covered on all four sides, yet in stretches of 50 feet or more, as in the case of iron I-beams and girders, the cumulative effect of expansion in uncovered iron might be a serious matter—quite sufficient with the rises of temperature due to a burning building to push out the bearing walls and wreck the building. Especially is this true of temperatures higher than 500 degs. It is unnecessary to suggest that metal differs from masonry in the important respect that heat does not travel throughout the entire length of the latter, while it does in the case of metal. In other words, while the difference between the expansion of a lineal foot of iron as compared with a lineal foot of masonry, marble, brick, etc., is very slight, the difference in conductivity is very great. The conducting power of silver, for example, being represented by 1, copper would be .845, cast iron .359, gold .981, marble .024, and brick .01—an important fact to be considered in the construction of buildings. Brickwork raised to a white heat would not raise the temperature of other masonry in the same wall a few feet away, but one end of an iron I-beam could not be raised to a white heat without raising the temperature of the beam for its entire length.

Where iron beams and girders are inserted in walls without sufficient space left for their expansion under heat they are almost certain to overthrow the bearing walls by their expansion thrust. A large warehouse in Vienna in which such provision had been contemplated by the architect was totally destroyed, with its contents, by reason of the fact that an officious subordinate, discovering the space in the wall purposely left at the end of each beam, deliberately poured liquid cement therein, which, having set, effectually thwarted the well-meant intention of the architect, and resulted in the destruction of the building. The expansion thrust of iron beams may be computed upon the following factor of expansion: Rolled iron of a length of 1,562 feet will expand one-eighth of an inch for every degree of temperature. The heat of a burning building as already stated is enormous—sufficient to fuse most known materials; it may safely be estimated to be at least 1,000 degs.; therefore a length of rolled iron of 1,562 feet at 1,000 degs. of temperature would expand about 125 inches and a 50 foot length of iron girder would expand between 4 and 5 inches, showing that there should be a play at each end of at least 2 inches if the iron is not fire-proofed. Inasmuch as in iron construction the iron beams and girders are usually anchored to the walls to steady them, space should be left and the tie to the anchor should be by a movable hinge joint, which would be of the same strength with an inflexible anchor for all tying purposes, but would yield under the thrust pressure like an elbow and allow play of the beam, or stiff anchors should have elongated holes to allow expansion when beams are of great length. Girders are seldom over 25 feet long, but if bolted together, as is frequently the case, they may be 120 feet or more long, and a line of columns from cellar to roof of a building may easily have one continuous iron structure of two hundred or more feet. It should be remembered, however, that this danger from the expansion of iron may be almost wholly counteracted by protecting it from exposure to fire through the use of non-conducting material. It is more important to protect girders than beams.

The mistaken pride with which the owners of some buildings point to exposed iron beams in ceilings as evidence that the floors are "fire-proof," actually justifying the supposition that they are left exposed for such display, would be ludicrous if it were not serious. In buildings occupied for offices or dwellings, where there is not sufficient combustible material to endanger the beams, it is not so objectionable; but in warehouses and stores, filled with merchandise, such construction is dangerous; and if one of the upper floors should give way it would come hammering down to carry all below and thoroughly wreck the structure. In this connection it is well to say that combustible merchandise should never be stored 100 feet above the street grade even in a "fire-proof" building, since the average fire department cannot reach it at that height.

The roof, that portion of a building which ought to be most carefully watched during construction, is often the most neglected, woodwork entering into the composition, as in the case of the Horne building, at Pittsburgh, where the cornice was supported on wooden outriggers.

Partitions.—These should not be erected upon wooden sills, as is sometimes the case—only, however, with ignorant and inexperienced architects, who suppose that it is necessary to use wood in order to nail baseboards and other trim at the bottom of the partition. Porous terra-cotta will hold nails and should be used in preference to wood, which, as soon as it burns out, will let down the entire partition.

(To be continued).

—At a meeting of the Board of Governors of McGill University, held July 28, Ernest Rutherford, M.A., B.Sc., Trinity College, Cambridge, was appointed W. C. McDonald Professor of Physics, and Dr. James Wallace Walker, of University College, London, was appointed W. C. McDonald Professor of Organic Chemistry. Both the new professors have had most successful careers hitherto, and we hope they will add to their laurels while at McGill.

JAMES MILNE, Mem. Can. Soc. Civ. Eng. Late Gen. Supt. Toronto Incandescent Light Co. Teacher Elec. Eng'g Steam and Steam Engine, Toronto Technical School.

Consulting Engineer

Plans, Specifications, Superintendent's Advice, Estimates on Steam, Hydraulic and Electrical Plants. Special machinery designed. **Specialties:** Steam and the Steam Engine, including Evaporative Tests, Efficiency of Tests of Steam, Hydraulic and Electrical Plants. Central station management; reports carefully prepared. **Office—80 Canada Life Building, Toronto, Ont.**

Tenders for Incandescent Electric Lighting Plant

TOWN OF THOROLD, ONT., CAN.

Sealed Tenders to be forwarded per registered mail addressed to the Mayor of Thorold, and bearing no later date of mailing than that of Wednesday, August 17th, 1898, will be received by the Municipal Council for the supply and installation of an Incandescent Electric Lighting Plant (1,500 to 2,000 lights, alternating current), according to specifications, copies of which may be obtained by applying to RODERICK J. PARKE, Consulting Engineer, 310 Foresters' Temple, Toronto, Ontario, Canada. The lowest or any tender not necessarily accepted.

Splendid Water Power

and special inducements to Manufacturers to locate on the

St. Maurice River,

PROVINCE OF QUEBEC.

The Shawinigan Water and Power Company is prepared to treat with parties desiring to lease large units of power. For information address the Company,

CANADIAN TRADE WITH SOUTH AFRICA.

A steamship has been chartered to convey Canadian exhibits to the Exhibition to be held shortly in the city of Graham's Town, Cape Colony. She will remain at Quebec till the end of the month to load exhibits. We understand that further information may be obtained from the Department of Agriculture at Ottawa regarding the Exhibition, and that exhibits will be carried and returned free of charge. South Africa is a promising field for Canadian trade. It has been exploited very successfully by American manufacturers and by a limited number of Canadian firms who have had the enterprise to invade that field. For the information of our readers we may mention that the population of Cape Colony at the census of 1891 was 1,527,000, of which 377,000 were whites. The population of Natal was 555,500, of which 42,759 were whites and 43,000 East Indians. The population of Pondoland was 200,000, of Zululand 146,000, Amatongaland 38,000, Swaziland 60,000, Basutoland 218,000, and of Betchulanaland about 66,000; these native territories having so far but a limited white population. The colonies and dependencies just enumerated are all British, but besides these there is the Transvaal Republic under the suzerainty of Great Britain, having a population of about 850,000, of which over 160,000 are whites. Besides the Transvaal there is the Orange Free State with a population of about 210,000, of which 78,000 are white. In the early days of sewing machines the Canadian Wanzer Machine was among the most popular in use in South Africa, and Canadian stoves, office and school furniture, sashes, doors, and house-building material, window shades, bicycles, type setting machines, agricultural implements and other lines of Canadian manufacture, have found greater or less favor in those colonies. American manufacturers, however, have hitherto had the lion's share of the trade because of their greater facilities for shipment and because of their greater enterprise. There is a large market, however, for Canadian goods in South Africa, and it only requires a little investigation to commence on, and a little courage and enterprise to follow it up, to develop a large and steady trade in that quarter of the world. The bulletins which the Canadian Manufacturers' Association propose to publish should serve a very useful purpose in directing Canadian trade into new channels abroad, and in the meantime much can be done by judicious exhibits at such exhibitions as that at Graham's Town.

PURIFICATION OF SEWAGE.*

BY E. G. BARROW, CITY ENGINEER, HAMILTON.

There are few questions of more interest than that of the best manner of disposing of the sewage of our towns and cities, and it may be also said few questions are beset with greater difficulties. When it is considered that this subject has occupied the minds of some of the most practical analysts, engineers and scientists of Europe for many years back, and even at the present day there still exists a great diversity of opinion as to the best method to be adopted, it may well be pronounced a question difficult of solution. It would seem wisdom to avoid becoming a partizan of any particular system, because it frequently happens that the surroundings of a city, the nature of the soil in its vicinity, value of land, etc., dictate the best methods to be adopted in each particular case.

The methods of purification best known at the present time are: 1st. Broad irrigation, or the distribution of sewage over large tracts of land, having in view the growth of useful crops, called sewage farming. This system will take 4,000 to 6,000 gallons per acre per day. 2nd. Land filtration, in which purification is obtained by the passage of the sewage through light soil with little or no attempt to grow crops; 60,000 gallons may be used to the acre on this plan. 3rd. Chemical precipitation, in which the purification is obtained by means of certain precipitants such as lime, alum, salts of manganese, sulphate of iron, which precipitate all the suspended matter in tanks, and also remove a small part of organic matter in solution.

Combinations of the above are frequently made. To these methods have been lately added the septic tank system adopted at Exeter, England; the biological method, by which the purification is sought to be obtained by means of bacteria contained in filters, generally made of coal, coke, polarite, etc.; the treatment lately advocated by Mr. Adeney, of Dublin, Ireland, in which after precipitation with salts of manganese the effluent is treated with nitrate of soda to complete purification.

Ordinary city sewage is a mixture of a very complex character and is derived from the discharge taking place

*A paper read before the Canadian Association of Stationary Engineers.

from water closets, sinks, and also manufacturing wastes, and in those cities having the combined system of sewerage, various substances from the streets. The quality of sewage in different cities varies considerably, the difference being largely caused by the nature of the manufacturing wastes which are received into the sewers. A gallon of ordinary sewage contains about 100 grains of solid matter, 30 grains being in suspension and 70 in solution, 60 grains of which are mineral and 40 organic matter, the analysis of which would yield to each 100,000 parts the following results :

Total Solids.	Suspended.	Alum.	Free Ammonia.	Organic Ammonia.
140	40	20	5	1

What is required to be done is the removal of all matter in suspension and as much as possible of the organic matter in solution. The organic ammonia or albuminoid ammonia is generally considered by chemists to be the most reliable index of the amount of polluting matter present in the sewage. The removal of the suspended matter is at present best done by means of chemical precipitation, but the effluent so obtained still contains organic matter in solution, which unless discharged into a large body of pure water is liable to set up secondary decomposition. The removal of the organic matter in solution contained in the tank effluent may be almost completely done by filters composed of either coal, coke, polarite, land, etc.

The advocates of the biological method of purification say that the matter in suspension may be liquefied by liquefying bacteria, which are cultivated and sustained by the air and sewage contained in the filter, and by this means the sludge would be entirely done away with. But grave doubts are expressed by sewage experts as to the ability of these bacteria or micro-organisms to perform this office, or in plain language they do not believe that they can "get away" with the sludge, and the opinion is generally held that with average town sewage there will be the sewage sludge accompaniment. A writer on this subject facetiously remarked that if the bacteria can be utilized to eat up the sludge, what a pity it is they cannot be trained to drink up all the liquid.

TANKS.

Precipitation tanks are made both circular and rectangular—their capacity being based on the maximum daily flow of sewage. If the quiescent system is adopted the tanks should be so arranged as to permit the liquid sewage to have at least a rest of 1½ hours. If the continuous flow system be adopted, then sufficient capacity must be allowed so that two hours at least will elapse during the passage of the sewage through the tanks. Provision has also to be made for the tank when not in use, and for the first part of storms. Experience has demonstrated that they should be of medium size, as very large ones have been found more difficult to manage. The parts in contact with the liquid sewage must be smooth, and the sludge drains should have quick slopes towards the sludge well. Experience has shown that no danger from freezing may be apprehended in this latitude in winter time. The precipitants most commonly used are lime, alum, soluble salts of manganese, sulphate of iron.

FILTERS.

A well-designed and well-operated filter, all agree, is a most excellent and efficient purifier of sewage. Formerly it was believed that its action was merely mechanical, or that of a fine strainer. Subsequently it was found that those polluting organic matters in solution contained in the sewage which had an affinity for oxygen underwent chemical decomposition and were transformed into new products of an innocuous nature, and this result was brought about by minute living organisms called nitrifying bacteria, so that in fact the purification was chiefly due to these bacteria. A filter should be so constructed that air can permeate its whole structure. It must also have periods of rest. The most modern way is to allow the clarified tank effluent to completely fill the filter so that the liquid just appears over the top of the filter ; after remaining there for about an hour it is discharged by opening a valve situated at the bottom of the filter. Very good results have been obtained, however, by allowing the sewage to be distributed over the surface of the filter by means of gutters, and allowing the liquid to filter slowly through. The filters should be several in number and each allowed a period of rest. The very best results have been obtained from filters composed of coal, the depth being about 4 feet and the sizes varying from ½ inch cubes to 1-16 inch cubes. It is said that coal produces a better effluent than any other substance experimented with, having a chemical as well as bacteriological action. I have been making experiments with coal filters and also with mixtures of coal and slag, and with sand and coke, and certainly the effluent from the coal filter is the best. It is necessary that all suspended matter be removed before the effluent reaches the filter. Sewage disposal has been more studied and has made more advancement in England, Germany and France than in any other parts of the world, but this has probably been caused, especially in England, by dense populations situated on the banks of comparatively small bodies of water (this does not apply to those cities situated on the seaside); whereas in America with the huge fresh water lakes and gigantic rivers into which the sewage is discharged, evil effects are not felt for many years, and it is only when the cities reach a large size that sewage purification becomes necessary and imperative. Now, both in the United States and Canada, cities and towns are beginning to feel the necessity of disposing of their sewage. Much may be learnt by experience gained in Europe, still I am of opinion that climatic differences and other purely local conditions will lead the American and Canadian mind, so prolific in invention, to perhaps improve on the European methods of purification, or at any rate to evolve some plans which will be particularly adapted to the needs of our climate and country.

The following practical deductions from the consideration of this subject suggest themselves: The sewage farm should only be selected when land situated near the city is suitable in character, and below or very little above the sewer outlets, and of reasonable price. If such land is not available and a high rate of purification is required, clarification in tanks by chemicals, followed by filtration, is the best plan. Collect by means of intersecting sewers all sewage to one station, so that all can be under one management. If part of the sewage needs pumping and part could be carried to purification station by gravity without pumping, then two stations might be the most economical. Such would be our case in Hamilton. In building a filter select the very best material, which I would say, without hesitation, is coal. It will give a better effluent and necessitate a less area than any other material.

The researches and experiments made by Mr. Adeney, of the Royal Dublin Society, on polluted waters, are of great value to the subject of sewage purification. He examined the gases contained in polluted water and the changes which took place in these gases, due to fermentation. These changes were caused by living organisms, and he discovered that it was necessary to supply them with oxygen in order to promote healthy bacteriolysis.

This oxygen he supplied by adding pure water (which always contains a certain amount of dissolved oxygen) to the polluted sewage water, and if sufficient was added purification was completed, but if not, putrefactive fermentation would take place. His examination revealed two distinct stages of bacterial fermentation; the first he called carbon oxidation, and the second nitrification or nitro-oxidation. The first takes place much quicker than the last and the liquid during the last stage will generally take oxygen from the air quicker than the organisms take it from the liquid. The conclusion which Mr. Adeney draws is that if the first stage, viz., bacteriolysis, can be made to take place at the disposal works, then the final stage can be allowed to take place in the river or lake into which the effluent is discharged, provided these bodies of fresh water yield the necessary amount of oxygen to complete the last stage of purification. I have thought that the method of purification advocated by Mr. Adeney is worthy of great consideration, as filters in our climate may not be successful unless covered over, and then the cost of roofing would be very great and require frequent repairs. Especially would this be the case in very large works where the filters would cover many acres. The buildings at the sewage disposal works should be neat in appearance, well lighted, ventilated and provided with al modern conveniences for the employees. Garbage destroyers should be built near the disposal works, so that the heat generated may be utilized to raise steam to run the machinery of disposal works, light the works and dry the sludge where precipitation works are in use.

Before concluding this paper I would draw your attention to one very marked improvement effected by our disposal works. Formerly at the outlet of the Ferguson avenue sewer, large quantities of excreta, animal substances, orange peels, paper, rags and offensive matter imprisoned in grease were discharged from the sewer, and at times were deposited by the wind along the shore where it became putrid and rendered the shore of the bay most offensive. Sometimes huge masses floated out into the bay and were deposited at the beach. Now this has been entirely done away with, and although we contemplated putting in filters at Ferguson avenue works, still I believe very good work has been already done.

SANITARY EXCESS.

BY WM. WATSON.

The Surveyor of London, England, reports an important meeting of municipal engineers held in Greater London, on Feb. 25th, to discuss the various methods of deodorizing and ventilating sewers, and to decide upon a uniform system throughout the municipalities, of public sewer ventilation. The meeting was necessary on account of the difficulties encountered by the municipalities (which have unwisely adopted the United States sanitary system) through the almost constant discharge of sewer gases from the ventilation grates in the centre of the street, and the failure of many expensive experiments made with the object of remedying the evil.

The examinations of the drainage plans of a recently built school in the South of England show the dangerous practices persons will resort to to act up to the fashion of the age. The drain in this case is taken the longest way round to the water closets and lavatories, bending squarely three times, and at each bend there is a catch pit or inspection chamber. There is also an interception trap, a breather, and large inspection chamber, which form impediments to the flow of the solids from the closet to the street sewer, causing a sluggish stream, that deposits the filthy matter at each and every angle and at the interception traps, there putrefying and generating gases that will find somewhere an exit and contaminate the atmosphere. The proper way to have drained the school was to avoid any impediments and run the drain pipe lines as straight and direct as possible from street to lavatories and then vertically above to the highest point of the school roof, having all rain-water leaders branched into the sewage pipe line.

The placing of interception traps on private drains cuts off the ventilation of public sewers, which they formerly secured through the house soil pipe that was carried forward through the roof, and the untrapped drain water leaders which, when in action, discharge large volumes of atmospheric air into the public sewers each time the sewage was discharged down the soil pipe, or when rainwater passed down the leader pipes. Then each and every soil pipe and rainwater leader formed a ventilation up cast shaft for the street sewers at short distances of only a few yards apart, which compelled the rapid circulation of fresh air down the surface grates of the streets and up the local pipes to the housetops. All this purifying element is abolished when the American system of sewer construction and the interception trap is adopted. Most cities and towns of Great Britain which have employed that system have to provide for the deodorizing of large quantities of foul gas that is constantly generating in the sewers, because they cannot now get the circulation of air needed to prevent the sewage and solid matter the sewage contains from putrefying during the time they are passing through the sewers to the outfall at the sewage disposal works. Thus we find that the natural ventilation is prevented. On the other hand it is proved that if sewage be not immediately treated by aerating influences it will commence at once to putrefy in the sewers and work mischief, and artificial methods of aeration or deodorizing must be resorted to or the public health will quickly suffer. It is known by experience that artificial means cannot be relied upon, though they are very expensive.

Under the old dispensation, when owners were permitted to put in their drains of broken pipes, bricks, or wood, with no regard for grading, for fall, or tight jointing, often pointing towards and following quite in the wrong direction, and when there were no general rules or designs adopted for the sewage disposal of the municipality on a comprehensive plan, a large number of such drains were totally useless as sewage carriers, and were nothing but cesspools generating sewer gases and distributing poisonous fluid into the surrounding subsoil. The Government became alive to the dangers of these evils and gave permission for each municipality to enforce such improved sanitary regulations as would effectively stamp out such dangerous practices and compel all drains to be constructed with good material and expert workmanship. When the Act of Parliament became operative a swarm of professional theorists, sanitary appliance manufacturers, interested tradesmen and public works contractors gathered round the various municipal authorities and pointed out to them that it was necessary to thoroughly remove the old sanitary abuses, that intricate and costly appliances, coupled with extremely drastic regulations that required an extensive staff of inspectors and other arrangements to apply them, were needed. Most unfortunately for the public health many municipalities were guided by such advisers and adopted their extreme ideas and thus spoiled the good work begun by overdoing it.

When the unnecessarily drastic regulations were enforced they naturally created a necessity for appliances to counteract the evil done. The natural ventilation which

the sewers formerly secured by the large volumes of air carried down the soil pipe by the sewage and rainwater leaders was shut off. The usual and constant circulation of air which formerly passed down the surface grates placed at intervals on the streets, and upward through each soil pipe and rainwater leader to the housetops out of everyone's way, was stopped and the public sewers were then changed from purifiers and destroyers of filth, to receptacles for the accumulation of foul matters and the rapid generators of poisonous sewer gases, which are now found to be very difficult to handle.

To try and destroy the evils thus created, various methods have been tried, and amongst a large number a few of the principal ones may be here mentioned, viz.: The flushing of sewers by water wagons and also automatic flushing appliances, and by creating a current of air with the heat from gaslights burning in the sewers; by connecting the head of each line of sewer o a tall ventilating shaft, or to a manufacturer's mill chimney, or into the ashpit under the steam boilers; by building vaults under the surface, ventilating grates in the streets, and installing deodorizing chemical evaporating machines intended to destroy the foul odors. When these artificial means are put in practice it is found they have each disadvantages unknown to the old natural ventilation processes. It is proved that having one ventilation shaft at the terminating head of each line of sewer is not sufficient, that air shafts are needed between each and all the street grates; that gaslights cannot be made reliable, for they occasionally either smother or blow out and then add to rather than reduce the nuisance. Flushing sewers allow plenty of time for the manufacturing of sewer gases between the periods of flushing, and ventilation is needed even when flushing is adopted. When chemical evaporating machines are used they need to be numerous, one for each grate, and even then the pressure in the sewers due to the want of circulation of air is often such that it forces the poisonous gas through the interception traps, which then passes either into the dwelling through the fixture traps or out of the breather pipes in front of the buildings on which they are placed at a level of within one foot of the ground line. All such apparatus are expensive besides and require constant attention and renewal.

The meeting of municipal engineers and surveyors already mentioned, after discussing the advantages and disadvantages of the different artificial methods of deodorizing sewer gases, decided to advise all municipalities to adopt so much of the old system of sewage ventilation as to ventilate each private drain by taking a branch pipe from the sewer side of the interception trap up to and above the top of the buildings. This is very good by just so much as it returns to the former systems of natural and local ventilation, but it still leaves the interception trap in each private drain that forms a catch bag, and often retains the solids of the sewage that passes through them, and in a short time chokes the private drain and totally disorganizes the house sanitary appliances; it also spoils and destroys the ventilation of the house soil pipes, because when there is any interception between the street sewers, and the terminating end of the soil pipe above the roof, it prevents the warm air of the street sewers from constantly moving upward through the vertical soil pipe and carrying along with it any foul gases that might generate in the waste pipes. To rely upon an upward circulation through a breather pipe placed at the foot of a house drain often fails altogether, because the current of air is sometimes changed to pass down from the roof to the ground line in place of passing upwards, first by the sewage passing down the soil pipes and carrying down large volumes of air with it, which is discharged at the ground line by the breather; second, then very often the breather pipe is not in working order through being choked, and third, by the variations in the temperature of the atmosphere.

The result of the surveyors' meeting proves that the expensive sanitary excesses and the interception trap is a total failure, but that the cost of the system has been thus far heavy and the standing and the reputation of the theorists have to be shielded, so that the intricate and obstructive system must be withdrawn slowly, even if by so doing they still further increase the cost of sanitary appliances. Let sanitarians compare the United States sanitary methods which have been adopted by Greater London and a few other towns of Great Britain, with the large stuff manufacturing city of Bradford, England. The authorities of that city have done everything possible to assist nature to keep their sewage sweet and odorless in the sewers until it arrives at the outfall of the sewage disposal works at Frizenall. The city is crowded to excess with large manufactories and dyeworks that discharge an enormous quantity of dirty or greasy water into the common sewers daily. And 90 per cent. of the population are employed in close greasy factories or other workshops; they live in houses closely built together, yet the inhabitants enjoy general good health, and their death and sickness rate will compare favorably with any other town, even where that town enjoys much more favorable circumstances. This can be largely attributed to the plain and efficient sanitary regulations enforced, and to the adoption of nature's laws in carrying out the principle of domestic sanitation. They do not allow bath or other small waste pipes to be connected directly with the street sewers, but each delivers its contents into an open grid and gully trap which conveys the sewage to the street drain. No sewer pipe which is connected in a direct way with the street sewer enters under any building except to serve a w.c.; then it is constructed of heavy lead or other good metal and joints. Soil pipes that serve water closets in upper rooms are run up outside the building when practicable, and the w.c. bend is taken through the outer wall at the nearest point and connected with the soil pipe outside, and the pipes fixed in this way work all right in frosty weather though the city is visited with long and severe frosts and snows in winter. They also put in as short a length of soil pipe as possible to do the work efficiently; weeping tile drains are never connected with any sewer drain, but deliver on to an open gully grate outside at the bottom of an area window if convenient. The sewage collecting sewers are generally taken along the back lane when the whole of sanitary appliances are in the rear rooms of the dwellings. If allowance be made for the smell that must come from the numerous open privy middens and the slop-water closets which Bradford still uses in many houses, then the city of Bradford is about the sweetest and healthiest manufacturing town that can be found. I may also say that they do not as a rule use back air vents to water closets; and it is unnecessary to use them for the traps, serving baths and any other small fixtures, because they are not connected directly with the sewers.

John Burke, Esq., North Bay, has secured a contract for lighting the streets of North Bay by electricity, and has placed an order with the Canadian General Electric Company, for a 25 light wood arc dynamo, and 15-double carbon brush arc lamps.

THE VICTORIA JUBILEE BRIDGE.

The Victoria Jubilee Bridge, on which such rapid progress has been made during the past few months, is well under way towards completion; in fact, it may be already said to be completed as far as being self-supporting is concerned, for no portion of it is now dependent upon the erection trusses, and the double line of rails will be laid throughout, just as soon as the old tubular bridge is removed. The work of erecting the superstructure of the first span from the westerly end was commenced on the

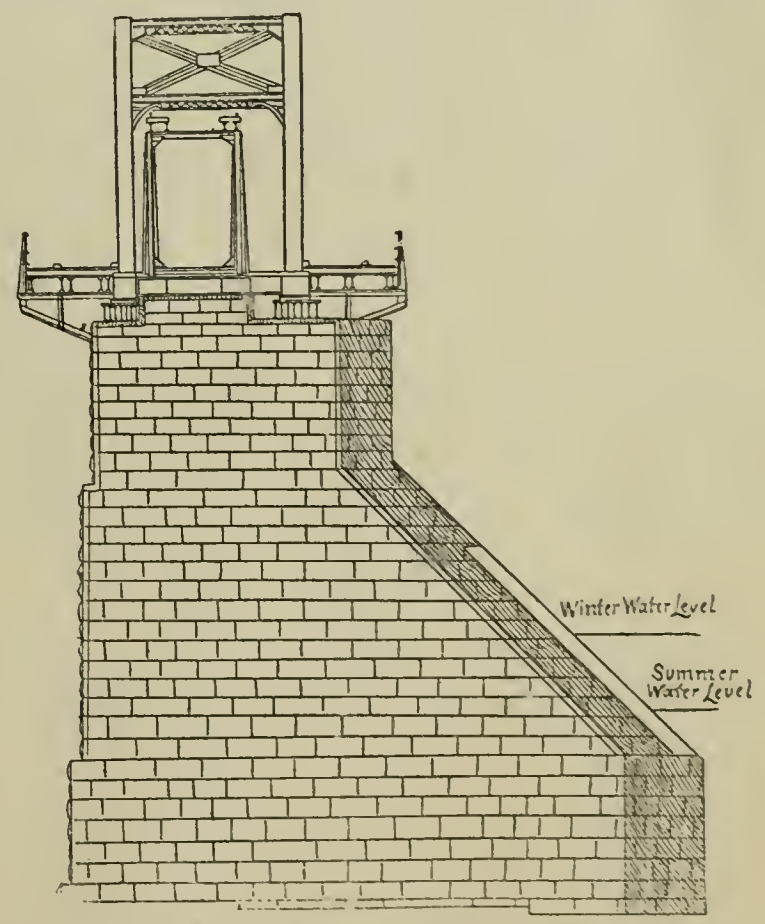
VICTORIA JUBILEE BRIDGE, MONTREAL, SHOWING UNFINISHED CENTRAL SPAN. THE VIEW IS FROM THE ST. LAMBERT SIDE, ABOVE THE BRIDGE.

8th December, last year, and it was completed on the 25th of the same month; but as it was almost impossible to carry on further operations during the winter season, the work of erecting was suspended until last spring. The second span was commenced on March 23rd, and the work progressed steadily during the season, with the result that on the 19th August the central span, which was the last one to be done, was all coupled up and resting upon its own bearings, thus practically completing the bridge proper. This has certainly been rapid work in bridge erecting, considering that between the 23rd March and 19th August, twenty-three spans, of 254 feet each, for double railway tracks and double tramways, and one 348 feet central span, of similar capacity, were erected in place, and that during this period of five months the aggregate amount of time that the present single-track bridge was closed to train service was only twenty-five hours.

The method of erecting the 254 feet spans has been described from time to time, and was carried on throughout on the same general principles. A temporary truss of as light a character as was compatible with what was required of it, was erected in proper axis on the ground at the entrance to the present bridge, and traveled across the tube by means of a series of trucks moving on the rails on top of the tube. Blocking was placed on these trucks to carry the truss by means of its top members, and the wheels were so placed as to distribute the weight as uniformly as possible in passing over the tube. The temporary truss was then drawn across the tube by means of block and tackle, worked by a stationary engine, securely placed on the top of the next tube.

As instance of how perfect the arrangements were for the moving of this temporary truss, it may be stated that the time occupied in the actual passage from pier to pier was only from four to six minutes in each case. After this truss had been placed exactly over its bearings on the piers it was lowered into place and the entire weight removed from the tube. During its passage over the present bridge and until it was securely placed upon its own bearings on the piers no trains were allowed to pass through the tube. This temporary truss being twenty-six feet two inches wide and thirty-four feet ten inches high, centre to centre of post and chords was therefore completely clear of the tube, and was then used as the staging for the erection of the permanent bridge. There were two erection trusses, one on each side of the centre, and as each permanent span was completed, the erection truss was moved in a similar manner for the erection of the next one.

The central span being so much greater than the others required a different method for the temporary work, and therefore the two erection trusses were used to form one. The plan adopted was unique; the one used on the westerly side of the centre was cut in two, and one portion of it removed to the easterly end of the one used on the easterly side. On the portion that remained some extra members were placed, forming a cantilever arm, and it was moved forward into position over pier No. 12, and securely anchored to the permanent bridge. On the half that was taken to the easterly side a similar cantilever arm was attached, and on August 7th the erection truss which had not been divided was traveled westwardly over the centre tube intact, in a similar manner to the others, and the pins driven connecting it with the west cantilever arm. The east end cantilever was then moved over pier No. 13, and after it was adjusted to proper position the pins were driven connecting the cantilever arm with the truss and it was firmly anchored at the east end to the permanent bridge.



THE ELEVENTH PIER AND SECTION OF TWELFTH SPAN.

The blocking on the trucks which supported the truss and carried it across the tube was then removed and this temporary span then rested on its own bearings, all foreign weight being entirely removed from the tube. Notwithstanding the exceptional care which had to be exercised in placing this truss, the time that the present bridge was closed to traffic was only five hours.

In regard to work remaining to be done in connection with the bridge proper the removal of the old tubes will be

the most laborious; the first span of the tubular bridge has already been taken away and it may therefore be said that that portion of the new structure is now in active use. The cutting of the rivets of the old structure and the removal of the various plates, girders, etc., entails an immense amount of labor, and it is of such a nature, and the field for operation is so limited, that the greatest care and caution have to be exercised in this particular part of the work, more especially on account of the incessant traffic moving in either direction.

VICTORIA JUBILEE BRIDGE, MONTREAL, SHOWING OLD TUBE SURROUNDED BY NEW STRUCTURE.

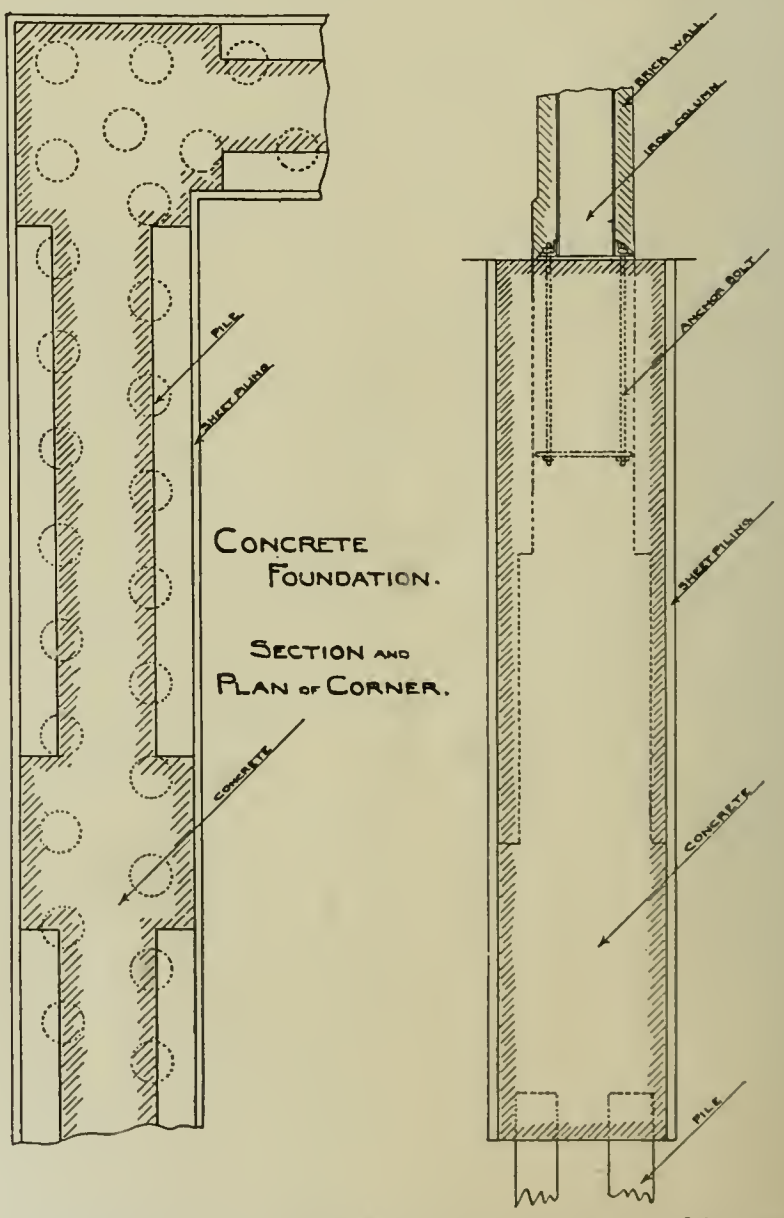
The old tubular bridge, as is well known, is a single-track structure, with a minimum clearance in height of only 15 feet. The new bridge will have a double line of railway tracks and a clear headway of 22 feet 6 inches. It will also have a team roadway and sidewalk on either side of the bridge outside the main trusses, which will be carried by the floor beams extended beyond the trusses. The total length of these floor beams is 66 feet. By way of comparison it may be interesting to note that the weight of iron-work in the old structure is 9,044 tons, whilst the new contains 22,000 tons of steel. Amongst other work yet remaining to be done is the widening of the embankment approach to accommodate the team traffic, but that is a minor matter, and will not interfere during its construction with the train traffic, nor yet with the bridge itself.

A CONCRETE FOUNDATION.

A somewhat unusual foundation has just been built for a new generating house the Consumers Gas Co. is erecting on Parliament street, Toronto. We believe it is the first of the kind in Canada. The building is to replace one that had to be torn down on account of the numerous cracks and settlements developed by faulty foundations. The foundations for this heavy building were simply rubble stone walls in lime mortar, walls that were built without any through bonders, plenty of "shiners," straight joints, parts laid up dry and all small stones; consistently with such work the walls were largely built on a soft made up bottom, one wall was carried down indeed sixteen feet below the ground level as if in search of hard bottom, which not only caused useless expense in the first instance, but also made the expenditure greater in the new work. Had piles been driven from four or five feet below the surface all round the building until they either gave an equal frictional resistance or reached hard pan, the first building would have cost less than it did and still be standing. This is a glaring instance of the greater costliness of rule of thumb methods in building over more scientific ones.

When the old foundations were removed the architects had test piles driven at intervals of about ten feet along the trenches and found the bottom to be so soft that the piles sunk to rock without practically developing any frictional resistance. Calculations were made therefore on the basis of the piles acting in direct compression, and from data thus gained it was determined to drive a double row of piles in the trenches at two feet centres staggered. These piles averaged a depth of about twenty-six feet from the ground level. They were cut off perfectly level twelve inches above the bottom of the trench and concrete filled in between to an even surface with the tops of piles, this thoroughly keyed the piles together and gave a good bed to build on.

On the recommendation of the architects, Bond & Smith, Toronto, solid concrete walls were then built to the ground level, part being sixteen feet deep. With walls such as this the loads from the superstructure (a steel skeleton building) are quite evenly distributed on the piles; Another point is that the column bolts are bedded right in the concrete mass and the whole is cohesive and rigid. The walls were stepped up in thickness from 3 feet 6 inches to 2 feet 3 inches.



The method of mixing and laying may be of interest: The concrete was formed of five parts of small broken stone, two of gravel and one of cement. After carefully examining tests of various cements a Canadian brand was specified by the architects, the Samson brand of the Owen Sound Portland Cement Co. All proportions were carefully measured in barrows of equal capacity, the stone was thoroughly wetted before being mixed with the other materials, the mixture was turned over four times to ensure thorough covering of the stone, only enough water was allowed to be added to make the mass cohesive, it was

then placed in the trench and tamped until the water came up to the surface. The walls were made in layers of not more than eight inches and wherever a joint occurred the layers above lapped over at least five feet in either direction; always before starting a new layer the lower one was "ragged" up, swept clean and watered thoroughly.

It is somewhat strange that this method of concrete foundation walls has not been more extensively used, for it is not only superior to an ordinary bonded wall, but has been found to be cheaper than a stone wall properly built in cement; doubtless though we shall see it adopted more often in the future now that a beginning has been made.

Some difficulty was experienced in carrying out this work through the heavy generators bearing on the ground a few feet from some of the trenches. On this account before allowing the old walls to be removed three-inch sheet piling was driven sixteen feet down. As the stone was taken out wales were placed along this and carefully strutted. At one of the other trenches it became necessary to underpin the stone wall of adjoining building before proceeding with the work.

CANADIAN ASSOCIATION OF STATIONARY ENGINEERS.

NINTH ANNUAL CONVENTION.

The ninth annual convention of the Canadian Association of Stationary Engineers was held at Hamilton, on the 8th, 9th and 10th August. The hotel headquarters were at the new Waldorf House, and the meetings were held in Oddfellows' Hall, John street.

The first session opened at 11 a.m., on Monday, 8th, with president, Bro. E. J. Philip, of Toronto, in the chair, and vice-president, Bro. W. F. Chapman, of Brockville, in the vice-chair. The other executive officers present were, J. G. Robertson, Montreal, secretary; R. C. Pettigrew, Hamilton, treasurer; G. C. Mooring, Toronto, doorkeeper. The delegates present from the branch associations were: Charles Moseley, John Fox, Wm. J. Webb, and Thos. Eversfield, of Toronto No. 1; John M. Dixon and John J. Richardson of Toronto No 2; Thos. Ryan and Peter McNaughton of Montreal No. 1; Geo. Mackie of Hamilton No. 2; Chas. Asselstine of Kingston No. 10; Wm. Allan, of London No. 5; John Grundy, of Brockville No. 15; Wm. Bear of Dresden No. 8; Wm. Oelschlager of Berlin No. 9; Thos. Pilgrim of Brantford No. 4; and John L. Wendell of Waterloo No. 17.

Other members reported present were the officers of Hamilton No. 2, consisting of Robt. Mackie, president; W. R. Cornish, past president; Thos. Chubb, vice-president; Joseph Ironside, recording secretary, James Carroll, financial secretary; Wm. Nash, treasurer; W. I. Stevens, conductor, and Thos. R. Carter, doorkeeper; Peter Stott, T. Cook, C. Hurton, J. Webb, T. Elliott, C. De Mille, W. Morris, J. Wadge, J. Clair, J. Fielding, David Hunter, Robert Stewart, J. M. Morris, and G. Epps, all of Hamilton; Geo. Gilchrist, Geo. Bradley, A. M. Wickens, Samuel Thompson, Walter G. Blackgrove, J. G. Bain, John Ruse, P. Trowern, all of Toronto; F. G. Mitchell, of London.

Among the visitors present were J. E. Taylor, representing the International Correspondence Schools, Scranton, Pa.

Executive treasurer Pettigrew, having introduced Mayor Colquhoun, and Aldermen Carscallen and Nelligan, of the Hamilton city council, the Mayor came forward, and in the name of the council and citizens, welcomed the association to Hamilton. The duty demanded of him was a pleasing one, for societies with such high ideals as this should meet with hospitality and friendship, wherever they convened. His chief regret was, that owing to the restrictions of a city by-law, which was as unchangeable as the laws of the Medes and Persians, he could not offer them the use of the City Hall as a meeting room, but he was glad to see they had comfortable quarters and plenty of room here. He hoped the delegates would carry back with them the most kindly recollections of their visit to Hamilton. They would be welcomed and "taken in"—using that phrase in a hospitable sense—and they would find the people of Hamilton kind and fraternal. Hamilton was a city to be proud of; it was of no mushroom growth; there had never been a boom since 1856, but its growth had been a steady, legitimate one, and that was what they wanted. Hamilton was now becoming known as one of the prettiest cities on the continent of America—an assertion with which the visitors would agree, he believed, before the convention was over. He might say more, but he was not an adept at figures of speech. As a banker he was more familiar with the figures that could not lie (laughter). In conclusion, he welcomed the delegates collectively and individually, and trusted their convention would be both pleasant and profitable.

Alderman Carscallen wished to emphasize the welcome extended by the Mayor, and was glad the association had seen fit to choose Hamilton as a convention city. He had been struck with the principles of this association, as announced in the preamble of the constitution, which he begged leave to quote: "This association shall at no time be used for the furtherance of strikes, or anyway interfering between its members and their employers in regard to wages, recognizing the identity of interest between employer and employee, not countenancing any project or enterprise that will interfere with perfect harmony between them; neither shall it be used in any manner for political or religious purposes." As long as this association is conducted on those principles, it would have the respect of every right-thinking man, and he would admonish all the members to adhere to those principles. He had always been in favor of organized labor, for the improvement of the condition of the workingmen, and as a means of obtaining their rights; and he had no hesitation in saying that the organization of labor had been the means of lifting men up. Union for mutual help and defence of interest was reasonable and seemed to prevail. As a councillor of some years' experience he would advise them never to be hasty in amending the constitution. A proposition might appear reasonable at first sight, but on second thought it would be seen to be a mistake. He hoped their deliberations would redound to the credit of the association.

Alderman Nelligan also expressed the pleasure it afforded him to join in welcoming the association to Hamilton. In the city council he was an advocate of day labor, as a means of getting good and efficient work, instead of awarding municipal work to contractors, who would squeeze the men and get all the profit there was in a job for themselves. He hoped the delegates would have a good time, and be pleased with their stay in the city.

Bro. Robert Mackie then read an address of welcome on behalf of the Hamilton branch, as follows:

"On behalf of the Hamilton Association No 2, I have a great deal of pleasure in extending to you, delegates of the Canadian Association of Stationary Engineers, at our 9th annual convention, a hearty welcome to our city. We might say that you are not strangers in a strange land, for you have been here at a former meeting of this kind, the Executive having been formed in our city. The continual growth of the association, however, has brought with it a larger number of delegates. It is not necessary to go into details of the advantages of engineers belonging to such organizations as ours. The members of the Hamilton branch received a great deal of valuable information last winter by a series of addresses and papers on subjects in which we are all deeply interested, given by the best authorities we could procure. In conclusion, we trust your stay with us will be a very pleasant as well as a profitable one."

The president appointed Bros. Ryan, Wickens and Blackgrove a committee to draft a reply to the addresses of welcome.

The president gave his annual address as follows:

I have the honor and pleasure to welcome you to this the 9th annual convention of the C.A.S.E. The subordinate associations have chosen you to represent them at this convention, and to look after their individual interest in particular and the whole society in general. The second meeting of the executive—it was really the first, the previous one being only a meeting to get into shape—was held in this city, and I little dreamt at that time that I would occupy the president's chair

at the next meeting in Hamilton; therefore, it is with pleasure that I greet you, the new members and the jolly good fellows I have met before. While this meeting should be a criterion by which we can judge the growth of the association, we must not forget the conditions under which the C.A.S.E. is carried on. First, it is not a labor organization, nor is it an insurance society, and it cannot be called a secret or benefit society, nor is it a political or religious order, it is purely an educational institution. Therefore the growth of the order is limited for several reasons. First, we have not the attraction that insurance, secret, benefit or labor organizations have. The field from which we draw our members is limited and scattered, and there are few places where there are plants enough to get a number of engineers to join an association; another reason is the fact that as boys at school hate to be taught, so we grow up, and it is hard to get a man to realize that he has much to learn, and as education is the only object for joining the association some object to letting the public know that there is anything yet for them to learn. Now, while the growth of the order is apparently small, at the same time the percentage of good done its members is much greater than any other order that I know of, as many can testify to. We meet again here this year to try and work out other ideas for the benefit of the order and each member individually. I hope you will all give your attention to the business that will come before you, that our meeting here may result in profit to ourselves and prosperity to the society. The prospects for the coming years are brighter than for years past; times are good in this country, and when the war is settled the big country to the south of us will brighten up and their prosperity will add to ours. So that if we grew in the past few years we will boom in the next. Hard times have had their effect on this order like all others, but hard times are a thing of the past in this country, and will be for some time to come, if I am any prophet, and if those who have been the stay of the association in the past will keep on pushing they will reap the harvest they have been looking for. Better work has been done in the subordinate associations during the past year, in the line of reading papers and making the meetings entertaining and instructive than other years; and it is noticeable the improvement in lodges where this matter is thoroughly carried out. I am pleased to state that Hamilton No. 2 is carrying this work out to perfection. There was one new association formed during the year in Toronto. It is a good live association and will materially help the order in Toronto and vicinity. The matter of a hand-book taken up last year was completed this. The secretary will no doubt make you a full report on the matter. I have not had the time to give to executive business that I would like, from the fact that this has been the busiest year with me that I have ever experienced, in fact, it was very difficult to get away to attend this convention; in consequence of this the work has all devolved on the secretary, and, as in past years, the secretary is by far the more important officer of the executive. So much so that it has been suggested that a permanent secretary be appointed, or at least have the secretary hold office for more than one year. As it is now, it takes a man the entire year to get accustomed to the work, and then he is changed, making confusion and loss of time to both executive and subordinate lodges that would be avoided by a permanent secretary. In conclusion, brethren, I hope you will give me the support that you have given the chair in the past, and that you will attend strictly to business while there is business to be done. I wish it were in my power to do all for the C.A.S.E. that I would like, and place it at the head of all societies, where it belongs, because it is founded on education.

Bro. Wickens regretted that duties in Toronto would call him away from the convention for the following day, but as he took a fatherly interest in the organization, having been one of its founders, he desired, with the president's permission, to make one or two observations before leaving. There were many different associations in existence, with various objects in view, but no association bearing on trade could be named which existed for the special purpose of educating its own members. The C.A.S.E. did this, and spent hundreds of dollars for the educational advancement of its members. How to extend and develop the educational plans of the association was a problem. Many engineers were scattered over a wide extent of territory in Canada, in many places it was not possible to form a branch association, and how to extend these advantages to such engineers was a problem worthy of consideration. He was glad to see city aldermen here, and would be glad to see city fathers in other places take an interest in our association. It was well for them to know that this association existed as much for the steam user as for the engineer. If the ideals of the association are lived up to, there was nothing to prevent it from becoming one of the greatest organizations in the country.

Secretary Robertson then read the minutes of the last convention, which, on motion of Bro. Moseley, seconded by Bro. Mooring, were approved.

President Philip nominated Bros. McNaughton, Mooring and Geo. Mackie to be the Committee on Credentials.

In the absence of Bro. Risler, of London, Bro. Allan, of the same branch, was appointed conductor.

Bro. Oelschlager, of Berlin, said, that as he would not be able to remain throughout the convention, he would take this opportunity of inviting the members to hold the next convention in his town. Berlin could not boast a big river or lake, but it had other attractions, and was becoming known as a convention town. Berlin was a prosperous manufacturing town, and he could assure the members that if they accepted his offer they would find a hospitable welcome.

Bro. Wickens approved of the idea, as Berlin and Waterloo, which were almost one, had each a branch association, and the Berliners knew how to take care of a convention.

The formation of committees was then proceeded with, as follows, the first-named member in each case being chairman:

Committee on Audit—Bros. Webb, McNaughton and Bear.

Constitution and By-laws—Bros. Ryan, Mooring, Allan, Pilgrim and Geo. Mackie.

Good of the Order—Bros. Dixon, Chapman, Eversfield, Moseley and Richardson.

Mileage—Bros. Pettigrew, Robertson and Fox.

Bro. Ryan gave notice of motion to have the following changes made in the constitution and by-laws:

1st. That the per capita tax paid by the different sub-associations be reduced from 70 cents per member, as at present, to 50 cents per member. .....

2nd. That with a view to reduce the expenses of the Executive Council, the meetings of the Executive be held biannually instead of annually.

3rd. Also with a view to reducing expenses, that the election of doorkeeper and conductor be dispensed with, and that these offices be filled at the convention by any delegates appointed by the president.

4th. That no District deputy be appointed by the president, but that all the executive officers fulfil the duties of District Deputy in different localities at any time.

5th. That all past presidents be competent to form part of the Executive Council with full powers and privileges, but that no mileage or hotel expenses be paid to any past president.

Bro. Wickens gave notice of motion that the Committee on Constitution and By-laws be requested to formulate a set of by-laws for the subordinate associations, and report the same at next convention.

The convention then adjourned till

TUESDAY, 9TH AUG.

The first business of the day was the presentation of the executive secretary's report. Secretary Robertson reported that during the year a new branch association had been formed in Toronto, known as Toronto No. 2, and they had succeeded in resurrecting the two defunct branches, Stratford and Wiarton. From Guelph, Ottawa, Winnipeg, Kincardine and Peterboro no report had been received as to per capita tax. The receipts of the year were $555.99, and after paying expenses the association had a balance on hand of $290.04. These figures did not include the expenses and receipts of the new handbook, which had not been issued long enough to enable them to make collections. This handbook had been compiled with a view to making it as useful as possible to the average engineer, and it had been exceedingly well received. It was acknowledged to contain more information than many books of five times its price. It was too early yet for the association to reap the full benefit from it, but that would come in the future. The financial results from it would be fully reported on at the next con-

vention, and meantime he might say that he hoped to turn in several hundred dollars to the association from it.

On motion of Bro. Pettigrew, seconded by Bro. Allan, the report was adopted, and Bro. Robertson and his co-compilers of the handbook were congratulated on their excellent work in producing such a valuable book at so much labor and trouble to themselves.

The Treasurer's report was as follows:—

The Treasurer begs to submit the ninth report of the Association.

Balance from last convention and receipts of the year	$559 99
Expenditure	269 95
Balance on hand	290 04

ROBERT C. PETTIGREW.

Auditors: W. J. Webb, Wm. Bear and P. McNaughton.

On motion of Bro. Mooring seconded by Bro. Asselstine, the report as passed by the auditors was adopted.

Bro. Ryan presented the report of the committee on constitution and by-laws as follows: This committee recommends unanimously the following:

1st. That the per capita tax be reduced to 50 cts. per annum for all members in good standing.

2nd. That the doorkeeper and conductor be not elected but appointed by the president from the delegates present at each meeting of the Executive Council.

3rd. That in article 10 section 1 the word "deputy" shall be struck out and "Executive Officer" inserted.

4th. That all past presidents remain members of the Executive Council with full privileges, but they must defray their own expenses.

5th. That the committee does not see its way clear to hold its conventions bi-annually.

Bro. Dixon presented the following report of the committee on Good of the Order. Your committee appointed to consider this important portion of our Society's life and development, have given due thought to the many suggestions that have been presented, and would submit the following conclusions to the mature judgment of the convention.

The president's report in a spirit of fraternity, welcomes all to take part in the convention. He further adds that our society is neither a trades or insurance association, and consequently our expenses should be reduced to a minimum. The educational portion of our meetings should have some form of systematic teaching, and all who are able should be asked to participate in this necessary and useful work. We believe that an advance in this direction would be instrumental in raising our organization to a permanent and educated membership.

We believe the time inopportune to change the per capita tax as the executive have liabilities which must be met for the current year, and any action taken in the matter might be a source of discredit to the order at large.

The suggestion of bi-annual meetings we regard as a fatal blow at our very existence. The vitality of a society consists as much in its intercourse and annual settlement as it does in its financial strength, and while the desire to economise may be commendable, yet we regard this step as one which in a measure would be suicidal.

The cutting off of doorkeeping and conductor proceeds from the desire to further economise, but we submit that such a course may act prejudicially, inasmuch as the conferring of this honor on members of small or remote associations keeps a thread of connection that is frequently of eminent service to the Order.

The services of district deputies should be dispensed with, and in the locality requiring the service of an executive officer, any member of the executive should be delegated to discharge the duties of the office.

The bulletin at present issued monthly to the associations should be enlarged to an 8 page Journal. It could be made an avenue of interest and information to our membership, besides it could be placed in the hands of those eligible to join our ranks, and possibly add materially to our numerical strength. We are further of opinion that such a sheet, by proper management, could be issued free of expense by a judicious system of advertising.

The office of executive secretary is one that should be held for more than one year, as a greater degree of perfection could be reached in secretarial work by a continuous service. The price of stationery as furnished to primary societies is on the side of excess, and we would suggest that a reduction of 10 or 15 per cent. should be made on all future sales.

It is a matter of regret that our bill in the Dominion Parliament was thrown out on a technicality; but we trust the combined wisdom of the present convention will devise some method wherein our profession may have due recognition and legal protection.

Both reports were received, to be discussed in detail later on. In the meantime a general discussion took place on the effect of the proposed changes.

Bro. Ryan said other organizations larger than this had got into trouble through fixing their per capita assessments too high, and there were some members of the Montreal association with whom this was a serious matter. Bro. Moseley wanted to know, if this tax were reduced, where the funds would come from to make up the deficiency. Toronto No. 1 had no complaint to make, as it had double the membership of any other branch; but a reduction all around would leave a shortage. He thought it should be left for another year. Bro. Pettigrew was in favor of a reduction and the association was now in shape to make it. Bro. Dixon said that big societies could afford to have a low assessment. He wished to be on the side of economy, but the present time was not opportune, and the branch association should be consulted in such a matter. Bro. Robertson said that as far as the immediate future was concerned, the association at large really depended for its income on the handbook just issued.

After further discussion Bro. Dixon moved, seconded by Bro. Richardson, that the executive secretary issue a circular to all the branch associations, asking them to state their financial position and express an opinion on the question of reducing the per capita tax, a report to be presented on the subject at the convention of 1899.

In speaking to this motion, Bro. Ryan said Montreal No. 1 had already instructed him on the matter. Bro. McNaughton said the dues to the branch associations barely covered the expenses, and if the per capita tax were reduced it would give them a fund to work upon. Bro. Moseley said Toronto No. 1 had been able to make way and pay out $200 in sick benefits in the last two years besides. Bro. Asselstine said Toronto was exceptionally well fixed. In Kingston, they found the tax quite a burden. Bro. Robertson said the big branches should help the little ones, if they wanted to see the institution grow; but he did not see how they were going to reduce the tax. President Philip, in reply to a question, said the proposed change in the officers would take off about two-thirds of the average loss from the reduced tax. On motion of Bro. Robertson, seconded by Bro. Moseley, the discussion was deferred; Bro. Dixon's amendment being lost.

On resuming discussion on the report of the Committee on Constitution and By-laws, the first clause, proposing to reduce the per capita tax, was defeated.

On the second clause, Bro. Dixon thought that if these offices were retained, the delegates elected—especially if from a small branch—would go back to their branches as apostles of the association. Bro. Ryan held that there were as good men in the small branches as in the big ones for any office, but as these offices could be filled by any delegate present, it was only throwing money away to have them as a part of the executive machinery. On being put to vote, the clause was rejected, and the offices of doorkeeper and conductor retained.

Clause 3 was adopted, the effect being to do away with the "district deputies," and make each executive officer an organizer in the district in which he may be visiting, or may reside.

Clause 4 was also carried, giving past presidents the right to vote, etc., at conventions, but without transportation allowance.

Clause 5 was also approved, maintaining the conventions annually, as at present.

On taking up the report of the committee on "Good of the Order," the president said Mr. J. E. Taylor, of the International Correspondence Schools of Scranton, Pa., would like to address the convention on the educational question. Permission being given, Mr. Taylor gave a history of the begin-

ning of this institution, which was founded by T. J. Foster, first as a means of preparing miners and mine engineers to pass the examination required by the State of Pennsylvania, and afterwards as a more comprehensive system of technical education for steam engineers and firemen, electricians, machinists, mechanical draughtsmen, designers, etc., to be carried on by correspondence in any part of the world. When the State law, requiring the examinations, was passed, many of the miners were in a difficulty, and Mr. Foster was asked to help them out by a set of questions and answers. It was thought that a class of 300 might be obtained at first, to cover expenses, but when the plan was placed before the men, 1,200 applied, and the idea has since developed, till now the I. C. schools have 50,000 students throughout the world. The student is taken right from the a b c of arithmetic up through algebra, etc., and as a correspondence is carried on personally with each student, a fair chance is given to backward pupils. The postage bill of the institution averages over $1,000 per week. Recently a kind of employment bureau has been started for obtaining situations for students, after they have passed, and a case was cited where the institution had been the means of obtaining situations for three young tool makers, at wages of $3.50 per day. The schools have 15 printing presses run by electric motors, and consume about two tons of paper per week.

A special discount was now offered to members of the C.A.S.E., and Mr. Taylor was prepared to explain all details to members interested. A branch office is being opened in Toronto, particulars of which are given in another column.

On motion of Bro. Dixon, seconded by Bro. Richardson, it was decided to recommend the methods of this school to the consideration and support of members.

On the question of continuing the issue of the "Bulletin," published for the past four months, Bro. Robertson explained that it was got out to advertise the work of the Engineer's Handbook, 1,000 copies per month being printed. It had served that purpose well, and the question now remained as to its continuance, either as a 4-page or an 8-page paper.

After further discussion, a committee, composed of Bros. Ryan, Dixon and Robertson, was appointed to confer with the publishers of THE CANADIAN ENGINEER in regard to the issue of the bulletin.

The convention then adjourned to hold an excursion on the steamer "Acacia" during the afternoon. About 50 joined in the trip, the steamer crossing Hamilton Bay and making a trip several miles out into Lake Ontario. A lunch was served on board, and the trip was enlivened by song and dance.

At the evening session E. G. Barrow, C.E., city engineer of Hamilton, read a paper on sewage disposal, which is printed elsewhere in this issue.

In complimenting Mr. Barrow on his instructive paper, President Philip said this was an important subject for Canadian cities and towns, and one that must be studied more seriously by our municipal authorities. Toronto, among other cities, stood in need of reform in its sewage system. There was one question he would like to ask Mr. Barrow, and that was the effect of the filtering operations on the coal used in the filters.

Mr. Barrow replied that after being used for two years in the filters, the coal was found to be as good for burning as before—in fact its burning qualities seemed to be improved, probably owing to the oily matter absorbed during its use. In reply to another question he said any kind of coal could be used, but it must be of small size.

Bro. Moseley asked what was meant by giving the filters a "rest?"

Mr. Barrow said that it meant the exposure of the material to the open air and sun, for an hour or more.

Bro. Geo. Mackie asked as to the relative value of coke or charcoal as a filter medium.

Mr. Barrow replied that they were not considered so efficient as coal. Replying to Bro. Mitchell, he said the sewage to be treated could be made to go up through the filter by pressure or down through it by gravity. The first layers of coal were coarse, and then finer coal was put on down to 1-16 inch. In reply to Bro. McNaughton, he said that in carrying out the irrigation system, it was desirable to make the area of ground broad enough to absorb the sewage without soaking the ground too much. On this account, in some localities, and in wet seasons, it resulted in too much soaking of the soil. The sewage was distributed over the ground by carriers. In the method of underground filtration, the most successful work was done at Berlin, Germany, where the soil was light and porous, and readily absorbed all the sewage. Replying to a question of Bro. Stott, he said that with the lime treatment a disagreeable smell developed, unless the treated material was quickly removed, but it was not so when the material was treated with manganese, which made a better precipitant.

J. M. Williams, of the chemical laboratory of J. Winer & Co., wholesale druggists, Hamilton, then read a paper on "Oils in the Engine-room." This paper will be found elsewhere.

The president, in complimenting the reader of the paper, said it was exactly in line with their work, and although many of them did not pay much attention to the composition of oils, all used them, and should be well posted on their nature.

Bro. Mooring would like a simple test of engine oils.

Mr. Williams said an oil was good, according to the degree of its viscosity, or body, and to test this in a simple way take a can and make a hole large enough to let out a drop at a time. Take a standard oil and count the drops that will come out of this hole per minute, and compare that with the outflow of the oil to be tested. To make the test fair, you must use the same can and the same hole, with the same amount of oil and at the same temperature for both oils. It is still better if two tests are made, one at a high temperature, and one at a low temperature. A viscometer is a desirable apparatus for such tests. As to testing the volatile properties of an oil, this can be done by placing a given quantity in a wide, open vessel and letting it stand a given time to see how much it will lose in bulk by evaporation. The oil that evaporates most is the poorest for lubricating purposes. Coal oil, for instance, which is very volatile, is of no use at all as a lubricant. Neither should an oil be gummy. Heating it in a vessel will disclose whether an oil is gummy, but this trouble will be found chiefly with oils that are derived from fish, or from animals and vegetables, and as most lubricating oils in this country are now of mineral origin, this difficulty is not common.

Bro. George Mackie asked if the volatility of two samples could not be disclosed by placing a drop from each on the cylinder and seeing which dried up the sooner. Mr. Williams replied that such a test was practical and convenient.

The president observed that some oils will run very slowly and yet be of no use on a heavy fast-running journal. He was one of the first who began to use light oils, and though he found the first trials unsatisfactory, one of the representatives of the Standard Oil Co. came around, and, after carefully going into the matter, proved that the difficulty arose, not from the new oil, but from the oils previously used, and after the bearings were cleaned of the former oils, all went well.

Bro. Moseley thought the best test of an oil was the crank-pin of a high-speed engine, running at 270 revolutions per minute.

In reply to Bro. Geo. Mackie, Mr. Williams said that any oil having resinous constituents (that is, of the nature of rosin), adds to the resistance in the bearings and increases the coal bill. In reply to Bro. Mitchell, regarding cylinder oils, he said there was no doubt that wet steam prevented lubrication in the cylinder. If the flash test was low it would be found that the oil, when put into the cylinder, would vaporize, or turn into a sort of steam, and therefore be no good as a lubricant. After discussing a particular experience of Bro. Mitchell, in testing a new cylinder oil, he would say that the flash test should not be too far in advance of the temperature of the steam in the cylinder, at 100 lbs. pressure. In response to a request for tests for oils, together with the usual ones of exposure to high temperatures for volatility, and drying, he suggested to have a bottle marked into thirds and shake together one-third of the oil in question and one-third clear lye (made by dissolving commercial canned lye in water and decanting); after standing mineral oil will rise to the surface, any animal or vegetable oil will be saponified and remain in the lower layer with the lye.

On motion of Bro. Moseley, seconded by Bro. Ryan, a vote of thanks was passed to Mr. Barrow and Mr. Williams for their interesting papers, and for the quiet way in which they had stood the cross-examination of members.

Bro. P. McNaughton then read a paper on "Evaporation and the Raising of Steam in Boilers," which will be found in another part of this issue.

President Philip said this paper disclosed a more than usual amount of study on this subject, and the reader had exhibited the qualities of his race in closely observing the small things in nature which ordinary people would pass over without notice.

On motion of Bro. Mooring, seconded by Bro. Mitchell, a vote of thanks was passed to Bro. McNaughton.

Bro. Chas. Moseley next read a paper on "Economy in the Boiler Room," which will be found elsewhere in this issue, and received a hearty vote of thanks, on motion of Bro. Pettigrew, seconded by Bro. Mackie.

The convention adjourned at 10.30 p.m.

WEDNESDAY, 10TH AUG.

On reassembling at 9.30 a.m., Bro. Dixon brought up the report of the committee on Good of the Order for discussion. With regard to the publication of the bulletin, Bro. Robertson said he had sent a copy, during the preceding four months, to every engineer whose address he could obtain, from Halifax to Vancouver, and where he could not get addresses, he addressed them to the waterworks engineer of the town or village. The question whether they should be sent to the branch associations and distributed to members from the rooms, or be sent direct to the private addresses of members, was discussed, it being the opinion of the majority that it would be better to send it to the houses of members, and each branch should have an address book in which the house addresses should be kept.

On motion of Bro. Geo. Mackie, seconded by Bro. Fox, the whole question of the bulletin was left in the hands of the committee appointed on the previous day.

On the subject of the laxity of branch associations in sending in reports of their meetings and recording their progress generally, Bro. Webb suggested that a printed form of report be sent to the various branches, on which they could report every month, and the Executive Secretary was authorized to prepare such a form.

On the clause of the report relating to the office of secretary, Bro. Dixon moved, seconded by Bro. Chapman, that the Executive Secretary be elected for a term not less than two years. In the discussion it was thought that the association lost much by having a new secretary every year, as by the time one secretary had become proficient in his work, a new man was elected, and the thread was broken. Organizations that had a capable permanent secretary showed better results. The resolution carried.

On the question of the price of stationery supplied to the branch associations, Bro. Robertson stated that the gross receipts of the year from stationery amounted to about $40, and the net profit amounted to about 25 per cent. In view of the smallness of this item it was decided, on motion of Bro. Mackie, seconded by Bro. McNaughton, to allow the present prices for stationery to stand.

The subject of the Bill brought before the Dominion Parliament, for licensing stationary engineers, was then brought up. Bro. Chapman, as one of the delegation sent to Ottawa, reported that along with Bros. Wickens, Mitchell, Ames and Simmons, he had obtained the active help of Mr. Wood, the local member, and the deputation was introduced to the Minister of Justice during the last session. The Minister of Justice showed, by the B.N.A. Act, that the Dominion Parliament had no jurisdiction on this matter, and that it must be brought up in the provincial legislatures. Through the different branch associations about 50 individual members of parliament promised to vote for the Bill, but the opinion of the Minister of Justice blocked the measure, and on the advice of their friends in parliament, it was not introduced into the house.

Bro. Ryan said a number of members of Montreal No. 1 had taken a lively interest in the Bill, and got the Montreal M.P.'s to favor it. Meantime the Bill had been dropped by the Ottawa delegation, who, instead of reporting the result, had allowed Montreal No. 1 to go on working and spending time to no purpose. This was a case of downright negligence, and was the cause of a good deal of annoyance to Montreal members, who should have been informed of the failure of the delegation.

Bros. Mooring, Chapman and Dixon agreed that the deputation to Ottawa were to blame, and should have reported the result of their visit in writing; and Bro. Chapman considered that every engineer in Ontario was to blame for not working harder to secure the passage of a Provincial Engineer's License Bill.

On motion of Bro. Pettigrew, seconded by Bro. Fox, the following were appointed a committee to take up the matter again, and endeavour to secure the passage of the Bill: Bros. Dixon, Allan, Webb, McNaughton and the mover.

An invitation was here received from the Hamilton Literary and Scientific Association to visit their museum on Main street.

The Mileage Committee reported that the total of the mileage allowances paid to delegates was $179.10, leaving a surplus still in the hands of the Executive of about $100.

Bro. Pettigrew was then requested to read the following reply to the address of welcome:

"To his worship, Mayor Colquhoun and Aldermen Carscallen and Nelligan: Gentlemen—We, as a body of engineers, extend to you our hearty appreciation of your cordial and kindly address of welcome to your pleasant and prosperous city, at our ninth annual convention. We, as a body of working men, do not believe in the furtherance of strikes or labor trouble of any kind. We are organized for educational purposes, in order that our employers may be benefited thereby, and thus ensure for them efficiency, carefulness and stability to reduce operating expenses generally. It is our aim to advance the interests of those by whom we are employed. It may be interesting for you to know that there are members of this association who are worth 100 per cent. more to their employers to-day than they were ten years ago, thus showing that their admission to the society was to their benefit as well as to their employer's. It is not our intention to laud our society as being the best on earth in regard to benefits, such as insurance, sick benefits, etc., but we do maintain that our society is the best organized for the advancement of its members in their calling. We are pleased to meet in your beautiful city, and trust that our meeting here may be beneficial to you and the manufacturer and steam user, as well as to ourselves, and hope that we may meet here again some time in the future. We wish to thank you for the hearty reception you have accorded us, and we assure you that we feel entirely at home here. We shall endeavor to conduct our business in the best manner possible, and trust our deliberations may be profitable to one and all. Again thanking you for your kind and enthusiastic greeting, we are yours respectfully, Thomas Ryan, Montreal; A. M. Wickens, Toronto; W. G. Blackgrove, Toronto."

Bro. McNaughton wished to ask the president what was meant by a "member in good standing."

The president replied that it was a member who was not six months or more in arrears with his dues.

Bro. Webb said that branch associations, by paying capitation tax on its delinquent members, obtained representation at the conventions to which they were not really entitled.

Bro. Mooring said this was a burning question in Toronto, and there ought to be some uniform policy adhered to in this matter.

The president said the real trouble was that the branch associations did not take off their books members who fell in arrears without special cause.

Bro. Webb said that in Ontario all associations were under the Ontario Assessment Association Act, and must give a member due notice of his suspension. In the case of Toronto, a good many members had been notified of their arrears time and time again. Members in arrears for one term before the convention have from the second meeting in June until the end of the month as a last chance. This was sufficient opportunity, and there ought to be no representation here from dead members.

Bro. Ryan said that in Montreal no member in arrears was carried on the books of the association unless he could show cause for non-payment.

On motion of Bro. McNaughton, seconded by Bro. Allan,

it was resolved that the local secretaries be instructed to enforce the by-law regarding members in arrears.

A question arose as to the numbering of the recently formed Toronto association, and Secretary Robertson said it was entered as "Toronto No. 2," at the request of the association itself. It was pointed out by some members that another branch being already known as No. 2, this would lead to confusion.

Bro. Geo. Mackie moved, seconded by Bro. McNaughton, that when the present stationery ran out, the name of Toronto No. 2 be changed to No. 18. Carried.

Bro. Dixon thought that locally the new Toronto branch could still be known as No. 2, and the No. 18 could be used in convention matters.

The convention then adjourned till afternoon, when Bros. Dixon, Asselstine, and Grundy were appointed scrutineers for the election of officers. The election resulted as follows, the first three being returned by acclamation:

President, W. F. Chapman, Brockville.
Vice-president, R. C. Pettigrew, Hamilton.
Secretary, J. G. Robertson, Montreal.
Treasurer, G. C. Mooring, Toronto.
Conductor, Wm. Bear, Dresden.
Doorkeeper, John L. Wendell, Waterloo.

Bro. Robertson moved, seconded by Bro. Dixon, that the next annual convention be held at Berlin.

Bro. Fox moved, seconded by Bro. Bain, that the next convention be held at Toronto.

Upon a show of hands the question was decided in favor of Berlin.

The installation of the new officers then took place, Bro. Ryan being appointed installing officer.

In the absence of the Mayor, Judge Snider performed the ceremony of pinning the past president's jewel on the breast of the past president, remarking as he did so, that he had heard of past president Philip's intelligence and uprightness in the discharge of his high office, and it gave him, therefore, especial pleasure in being the medium of presenting the jewel. Bro. Philip replied in suitable terms. The work of the officers was carried on under difficulties, and the only way to make it a success was for each one to do what lay in his power.

Bro. Ryan was then asked to present himself before Judge Snider, and was evidently surprised at the request. He was still more surprised when a past president's jewel was taken out of a case and pinned on his breast. Judge Snider assured Bro. Ryan that this token expressed the feeling of reverence and esteem in which the association held him for his past efficient services.

Bro. Ryan said he could hardly tell how surprised he was at this manifestation of good-will, and he could only say just now that he would persevere in his efforts to promote the good of the association.

On motion of Bro. Dixon, seconded by Bro. Mackie, a vote of thanks was passed to Judge Snider for his kindness in attending at this function; and a similar vote to Bro. Ryan for the way in which he had fulfilled his duties as installing officer.

On motion of Bro. Mooring, seconded by Bro. Mackie, a gratuity of $25 was presented to Bro. Robertson for his efficient services as secretary.

The price of the new handbook was fixed at 25 cents to members, and 50 cents to outsiders.

On motion of Bro. Dixon, seconded by Bro. Philip, a vote of thanks was passed to THE CANADIAN ENGINEER for its report of the convention, and the interest it had taken in the progress of the association.

Bro. Wickens, who now arrived, being asked as to the license bill, said a circular had been sent to all members explaining the proposed Bill and soliciting their support. About 50 promises were received, but when the deputation went before the Minister of Justice, he held that under the B.N.A. Act, the Dominion Parliament had no jurisdiction. The Marine Engineers were brought under license from the Federal Government, because they were a part of the machinery of the trade and commerce of the country, over which it had jurisdiction, but it was not so with Stationary Engineers. Hence the Minister argued that the Provincial Government only had the right to pass such a law. The Ontario Association of Stationary Engineers had put up the expenses of the deputation, to the extent of $200, and they had appropriated $150 more for prosecuting the measure in the Ontario House.

After some discussion it was decided that the committee of this association should co-operate with the committee of the Ontario Association of Stationary Engineers, with a view to obtaining the necessary legislation.

On motion of Bro. Philip, seconded by Bro. Fox, a hearty vote of thanks was passed to Hamilton No. 2, for its hospitality and the pains it had taken to make the convention a success. Bro. Ironside said that it would afford him pleasure to convey the resolution to his association.

On motion of Bro. Ryan, seconded by Bro. Fox, it was decided that the expenses of the hall be paid for out of the funds of the Executive.

After a vote of thanks to the city press, the convention closed, and the delegates went on a trip of observation around the city, visiting the new sewage disposal works (described in THE CANADIAN ENGINEER of Jan., 1897), where they were shown the various processes by Bro. Robt Mackie, the engineer in charge; and visiting also the Victoria Yacht Club's establishment, the House of Refuge and the Street Railway power house. The delegates were presented at the City Hall with a copy of the handsomely printed "Souvenir of Hamilton," and in the evening they were the guests of the Hamilton Street Railway Co., in a ride about the city on a special car.

THE BANQUET.

The proceedings of the convention were brought to a close by a very successful banquet, given in the large dining-room of the Waldorf. This was the maiden dinner in the new hotel, and the impression made by the management was certainly very favorable. Over 100 guests sat down to the dinner, which was presided over by Robt. Mackie, president of the Hamilton branch, who made an excellent chairman. He was assisted by the following members of the Hamilton branch, who acted as dinner committee: J. Ironside, secretary; W. R. Cornish, W. Stevens, R. E. Chilman, Thos. Chubb, and Geo. Mackie.

After reading letters of regret from Mayor Colquhoun and others, who were prevented from attending, the toast list was taken up. The "Queen" was followed by "Canada our Home," to which Stuart Livingstone responded, referring to the romantic and stirring incidents that abounded in the three and a half centuries of Canadian history. He gave a glowing eulogy of the U. E. Loyalists, those heroes and heroines who left all to maintain their allegiance to the empire, who, having no houses, no villages, no post offices, no railways or telegraphs, and no newspapers to record the story of their wrongs, followed the northern star, and worked out their destiny in pain and trial, but with a never faltering loyalty. It was the thought of what these loyalists had done for Canada that nerved us to the struggle of 1812, and had inspired us to every high national endeavor since; and there was no man here who could not be thrilled with the story of brave Laura Secord, who threaded her way 20 miles through the dense woods to warn Lieut. Fitzgibbon, and enable him to capture a force of Americans of ten times his own. The speaker referred to the many Canadians who had achieved fame abroad—in India, Egypt, and other remote lands—and to the vast opportunities there were for great achievements in our own wide domains, which our fathers won by right of purchase, but which we have by right of birth. "The Mayor and Corporation" was replied to by Ald. Nelligan, and ex-Mayor Blaicher. The former regretted the absence of the Mayor, who was in Toronto attending his duties as member of the legislature. His statement that a copy of the "Souvenir of Hamilton" was being presented to each delegate was received with cheers. He concluded by hoping that in the near future the convention would come back to Hamilton. Ex-Mayor Blaicher was pleased that the convention had received a hearty welcome, and he commended them for their principle of non-interference in strikes, which had done a great deal of harm to Hamilton in days gone by. He was proud of the scenic beauties of Hamilton, and its neighboring country, so famed for its orchards and vineyards, and was equally proud of the fact that the manufactures of Hamilton now commanded the confidence of the whole Dominion, while some of its products were known and esteemed in foreign countries. "The Manufacturers" was responded to by ex-Ald. A. H. McKeown and J. H. Clappison,

of the Clappison Pipe and Boiler Covering Co Mr. McKeown said the manufacturers of Hamilton had confidence in this association, knowing that if they employed a member, they were sure to have an efficient engineer, and generally a trustworthy man. The manufacturers recognize that in this way the association has been a great benefit to themselves. Mr. Clappison expressed the pleasure it gave him to reply to this toast. Being a manufacturer himself, he was proud to realize the truth of the statement already made that Hamilton now took a leading part in the industrial development of this country. The quality of Hamilton's special manufactures was constantly rising in the estimation of the people. He was glad that the delegates were going away pleased with their reception, and he hoped when the next convention was held here, that they would come in three times their present numbers. The toast of "Educational Interests" was coupled with the name of W. H. Ballard, public school inspector; J. M. Williams and Percy Domville. Mr. Ballard said if citizens of Hamilton were proud of their advance in educational matters, they owed it to themselves. The school attendance in the city had increased 70 per cent. in the last 13 years, and the general work of the schools had doubled in the last 10 years. Over $250,000 was now invested in school property. Mr. Williams referred to the pleasure he took in being with the association, as while he may have taught them some things he had also learned from them. Mr. Domville, in his speech, advised steam engineers to learn something about electricity, which was creeping into so many lines of manufacture. In a few days they would have the electric current, generated 30 miles away, turning wheels in Hamilton. Some went so far as to say that electricity would do away with steam altogether, but he did not think this would come to pass, as there were plants that could be run more cheaply by steam even when the electric current was brought into Hamilton. "The Executive Head" was responded to by past-president E. J. Philip, who was glad to say that the Executive was in better shape this year than for some years past, and he hoped it would be in still better shape next year. He was always glad to come to Hamilton, for he thought very highly of the city and its citizens. President W. F. Chapman followed, expressing his pleasure at meeting the people and the engineers of Hamilton, who should be proud of their beautiful city. As president of the association, he hoped to follow in the footsteps of their popular past-president. Secretary J. G. Robertson and treasurer G. C. Mooring also replied, complimenting the Hamilton branch on the good work it had done. Telegrams were read from Albert E. Edkins, of Toronto, and John J. York, of Montreal, both past presidents, conveying their felicitations to the assembled guests. "Sister Associations" was responded to by J. M. Wickens, representing the Ontario Association of Stationary Engineers. He referred to the new Cataract Power Co.'s works, and pointed out that through the work of the C.A.S.E., there were plants in this city that had got the cost of steam down to such a point that the new electric power company could not displace it. Another thing the C.A.S.E. had accomplished was the institution of technical branches in the high schools of Ontario; while the establishment of the Toronto Technical School, which had shown such excellent results, was also due to it. "The Press" was replied to by E. B. Biggar, of THE CANADIAN ENGINEER, and by Messrs. Reid and Kirkpatrick, of the Spectator and Times. "The Ladies" were championed by Thomas Ryan, Montreal, J. M. Dixon, Toronto, and P. McNaughton, Montreal, and while all three spoke extremely well, it was admitted that Mr. Dixon's was the speech of the evening, and he came off with honors, both as an orator and entertainer. "The Host and Hostess" concluded the toast list, and the company broke up about 2 a.m. The musical part of the programme was well rendered by James Jardine, Geo. Allan, E. T. Martin, W. W. Barlow, J. Grant, and J. M. Dixon, B. Arthur being accompanist.

W. F. Chapman, president of the Canadian Association of Stationary Engineers, was born at Gananoque, Ont., and was in business for some time with his father, John Chapman, who operated a cheese and cheese box factory there. He picked up a knowledge of engineering in his father's factory, and having studied electricity, gained enough knowledge of that business to instal the electric plant for Cooke Bros. at Lachute. After running this plant for some time he installed a plant at the Taylor & Walton Carriage Co.'s Works, this company being also owners of the Gananoque Electric Light and Water Supply Company. He then went to Brockville, and was appointed

W. F. CHAPMAN, PRESIDENT, C. A. S. E.

engineer of the Canada Carriage Company, which position he has filled till the present time. That Mr. Chapman has the esteem and respect of his fellow engineers is evident by his appointment to the highest honor in the association.

R. C. PETTIGREW, VICE-PRESIDENT, C. A. S. E.

A biographical sketch of Robert C. Pettigrew, who has been elected vice-president of the C. A. S. E., has already appeared in The Canadian Engineer. Mr. Pettigrew, who is in business as a coal merchant in Hamilton, has not only been a generous helper in all that concerns the progress of the C. A. S. E., but has for many years taken a lively interest in the municipal affairs of Hamilton. He was for three years on the School Board, and is now an alderman, representing Ward No. 7, having been returned at the top of the poll.

G. C. MOORING, EXECUTIVE TREASURER, C. A. S. E.

G. C. Mooring, executive treasurer of the C. A. S. E., was born at Evenly, Northampton, England, and came to Canada in 1874, when he obtained employment with Thompson & Williams, of Stratford, as machinist. Having learned the business there, he came to Toronto in 1878 working successively at the

Toronto Reaper & Mower Works, the Massey Company's Works, the Toronto Bridge Works and the Standard Woolen Mills. For the last nine years he has been in the employ of the Methodist Book Room, as engineer of their large printing and binding establishment. His father was also an engineer.

J. G. Robertson, executive secretary of the C. A. S. E., was born in St. Johns, Que., and on reaching the age at which he felt able to make his own way in the world, went to Chicago and apprenticed himself to Crane Bros., the large valve makers of that city. After living in the United States in various cities, as machinist, for about 17 years, he returned to Canada about twelve years ago and settled in Montreal. He was appointed engineer of the Montreal General Hospital, a position he has ably filled ever since.

WM. BEAR, CONDUCTOR, C. A. S. E.

William Bear, conductor of the C. A. S. E., is a native of the State of New York, but came to Canada at the early age of 3 years, and may therefore be considered a Canadian. Mr. Bear has been fourteen years an engineer, all of which time he has served in Dresden, where he is now chief engineer of O. & W. McVeane's spoke and hub works.

JOHN L. WENDELL, DOORKEEPER, C. A. S. E.

John L. Wendell, doorkeeper of the C. A. S. E., is a native of the thriving town of Waterloo, Ont., and represented the Waterloo branch of the C. A. S. E. at this year's convention. Mr. Wendell has been about six years an engineer, and is now assistant engineer at Seagram's large distillery in Waterloo.

Thomas Ryan, engineer of the Federal Government buildings, Montreal, who was presented with the past president's jewel at the Hamilton convention of the C. A. S. E., was born in Quebec 62 years ago, and his father and mother before him were both born in the same city. Mr. Ryan served his apprenticeship as a machinist in the shops of Calvert & Tweedall, of Quebec, and after serving his time obtained his first engagement as engineer on the steamer "Blue Bonnet," running from Montreal to Cornwall. He was then less than 20 years of age and was the youngest engineer of his time on any large Canadian boat. After having charge of the engine at the dry dock works of Millin & Milne, Montreal, he was appointed engineer of a dredge under the Public Works Department. After remaining there several years, he was taken into the service of the Ottawa River Navigation Company as engineer of the steamer "Prince of Wales." After remaining with that company for 16 years he entered the service of the Quebec, Montreal & Ottawa Railway Co., now a part of the C. P. R. system. For the past 16 years he has had charge of all Federal Government buildings in Montreal, which responsible position he

THOS. RYAN, PAST-PRESIDENT, C. A. S. E.

has filled with eminent ability. His ripe experience, good judgment and sound practical engineering knowledge have won the confidence of each successive Government. While Mr. Wickens is looked on as the founder of the Toronto branch of the C. A. S. E., Mr. Ryan may be called the father of the organization in Canada, having formed the pioneer association in Montreal about 1883. He, with George Hunt and Harry Wilson are, so far as known, the only members of the original association still remaining. In response to a circular issued by Mr. Ryan, about a dozen engineers gathered in the old Sunderland House, St. Lambert's Hill, in the year mentioned, and there formed the first Association of Stationary Engineers, the constitution being based largely on the National Association of Stationary Engineers of the United States. Mr. Ryan also took part in founding the first association of engineers for the benefit of French Canadians, who from lack of knowledge of the English language, were unable to reap the full benefit of the English Association. Mr. Ryan is a prominent member of St. George's Lodge, No. 10, A. F. & A. M., and is a past officer of the Grand Lodge of Quebec.

ANSWERS TO CORRESPONDENTS.

A. W. E., Lennoxville.—We have advised you privately as to the makers of acetylene lamps.—Ed. Can. Eng.

G.—In answer to your question about the fairness of the specifications upon which tenders were called for an electric lighting plant, it appears to us that the specifications of an individual make of apparatus, as the lamp for example, would naturally shut out from tendering the makers of rival appliances —Ed. Can. Eng.

MECHANICAL STOKER TEST.

The General Engineering Co., of Toronto, Ltd., successors to the Weeks-Eldred Co., are installing six of the Jones Underfeed Mechanical Stokers in the mills of the Laurentides Pulp Co., of Grand Mere, Que.; twelve in the pulp mills of the Maritime Sulphite Fibre Co., of Chatham, N. B.; twelve in the power house of the Toronto Railway Co.; two in the new C. P. R. station at Dalhousie Square, Montreal, and a second order for the Windsor Hotel, Montreal.

A commercial test was made recently on two boilers at the power house of the Toronto Railway Co., for the purpose of determining the saving in fuel effected by the Jones Underfeed Mechanical Stoker. The boilers tested were of the cylindrical, return-tubular, internally fired type, 9 feet 9 inches diameter by 14 feet long, each boiler having two corrugated flues 39 inches inside diameter and 80 tubes 4 inches diameter, 14 feet long. The report of the test published by the company shows a saving in fuel effected by the stoker for equal evaporation of 15.2 per cent., and increased evaporation for equal fuel equal to 17.93 per cent.

THE LATE SIR CASIMIR GZOWSKI.

SIR CASIMIR GZOWSKI.

Col. Sir Casimir Gzowski, A. D. C. to the Queen, died at his residence, "The Hall," Bathurst street, Toronto, Aug. 24th.

Casimir Stanislaus Gzowski was descended from an ancient Polish family, who in the 16th century were ennobled, and who for a period of 200 years after their elevation continued to exercise great political influence in Poland. The father of Col. Gzowski was known in Poland as Stanislaus, Count Gzowski, and held a commission in the Russian National Guard. Sir Casimir was born in St. Petersburg, Russia, in 1813. At a very early age he entered the military college at Kremenetz, Province of Volhynia, where he pursued a course of military engineering, and in 1830, having been in the college eight years, he graduated as an engineer, and was awarded a commission in the Russian army. It was at the time of his first entering the Imperial army that one of the periodical insurrections occurred arising from the discontent of the Polish people at the severe treatment of Constantine, brother of Emperor Nicholas, who was made military governor of Poland. An organized revolution finally broke out, in which most of the Polish officers in the Imperial army joined. This revolution culminated in the expulsion of Constantine, who, with his court and Russian adherents, were driven from Warsaw. Young Gzowski, who had just received his commission at the time of the first outbreak of the insurrection, immediately joined his compatriots, and played a conspicuous part throughout the insurrection, and was present in Warsaw in November, 1830, when the Grand Duke Constantine was expelled.

As is well known, Russia and Austria, after bloody conflicts, lent their assistance to quell the insurrection, and Warsaw was recaptured from the Poles by the allied forces under Count Paskevitch in 1831. The prisoners taken at Warsaw on its fall were either condemned to die or to linger in the mines of Siberia. After the battle of Baremel, Gen. Devernicki's division, to which Gzowski was attached, retreated to Austrian territory, and the division surrendered. All but the officers were allowed to go wherever they pleased, but the officers were condemned to military prisons for some months, when an arrangement was entered into between Austria and Russia, and the whole of them were shipped to the United States, Colonel Gzowski among them. Colonel Gzowski landed with his fellow exiles in the United States without a penny. He found that owing to his lack of knowledge of English his engineering skill would not be very remunerative, so he set to work to learn the language, and for a time taught French and German in New York. Subsequently he articled himself to Parker L. Hall, a lawyer of Pittsfield, Mass., and studied law. During these studies he maintained himself by giving lessons in modern languages, drawing, and fencing, in the local academies. In 1837 he began the practise of law in Beaver county, Pa., and remained there until 1841. From 1841 to 1846 Mr. Gzowski was employed in the Public Works Department of the Canadian Government. In private practice after leaving the employ of the Government, the first great enterprise with which Mr. Gzowski was connected was the St. Lawrence and Atlantic Railway Company, from Montreal to Island Pond. He was appointed chief engineer, and was practically engaged on the construction of this railway. This appointment he resigned when the railway became merged in the Grand Trunk Railway. Subsequently a partnership was formed, the firm consisting of Sir Alexander Galt; the late Luther H. Holton; the Hon. D. L. Macpherson, and C. S. Gzowski. This firm on the 24th of March, 1853, obtained the contract for the construction of a line of railway from Toronto to Sarnia. The work was attended with enormous profit, and was satisfactorily completed. Among other railway works completed by the firm of Gzowski & Macpherson is the line from Port Huron to Detroit, and from London to St. Mary's, in the Province of Ontario. One of the most noteworthy and successful feats of engineering performed by the firm of Gzowski & Macpherson was the building of the International bridge over the Niagara river, at Buffalo. The charters for the construction of this bridge were granted by the Legislature of Canada and State of New York in 1857. The funds for its completion were raised in England in 1870, and the bridge was completed November 3, 1873, the cost of construction amounting to over $1,500,000. He was the chairman of the Queen Victoria Niagara Falls Park Commission.

Sir Casimir was connected with many financial concerns during his long career. He was at various times president of the Toronto Club, for some years president of the London and Canada Loan and Savings Company, president of the corporation of Wycliffe College, and vice-president of the Ontario Bank. He was appointed lieutenant-colonel of the Central Division of Volunteers in Toronto, in 1873. His last and highest promotion was that of full colonel, and in May, 1879, he was appointed aide-de-camp to her Majesty Queen Victoria, being knighted K. C. M. G. a year later.

F. NAPIER DENISON.

F. Napier Denison was educated at Upper Canada College and entered the Toronto observatory, but finding promotion slow, went to Boston and studied electrical engineering. After obtaining a certificate he traveled for six months throughout the United States as electrical expert for the Thomson-Houston Electrical Company. In 1891 he came to Canada and joined the Excelsior Company. During 1892 he spent six months traveling throughout the various countries of Europe, where he obtained much valuable electrical information as well as attending special

F. NAPIER DENISON.

lectures in London. During 1893 he perfected his electric dental engine, which has been patented in many countries, and is being successfully manufactured in Canada, not only for a large home, but also British, trade. This was followed by many others (all patented), including an electric transmitting thermometer, an electric brake, a new grain bin and heat detector, a combined shaving brush and soap holder for travelers. After re-entering the meteorological service in 1895 he devoted his inventive ability to the benefit of this service, and has devised an electric anemograph or automatic instrument to record both the direction and velocity of the wind, a simple form of "hydrograph," set up at the mouth of the Humber River to record the lake undulation; and as it was thought these undulations were due to atmospheric waves, he devised a self-recording barometer seventeen times as sensitive as the ordinary mercurial type.

which was set up at the Toronto observatory. By studying corresponding records from both instruments, the direct action of atmospheric waves as causing the water undulations was clearly shown. In July, 1897, Mr. Denison devised a combined instrument to record both lake and atmospheric undulations upon the same time cylinder, and set it up in place of the former instrument. This device, which has been termed a "hydro-aerograph," was fully described in a paper read before the Toronto meeting of the British association last year by the inventor, a reprint of which appeared in the October and November numbers of this paper. Last May Mr. Denison constructed for the Public Works Department, Ottawa, another form of hydrograph, which has been set up at the Queen's wharf, Toronto. Mr. Denison has left Toronto for Victoria, where he is to start weather forecasting for the Province of British Columbia, issued in the same manner as those from the central office, Toronto. A sensitive hydro-aerograph is to be installed there, as it is hoped the records from some will tend to assist in warning the approach of storms, which sweep in off the Pacific Ocean.

FIRES FOR THE MONTH.

Aug. 3rd The Canadian Rolling Mills, Peck, Benny & Co., Montreal; damages amounted to $75,000; insurance, $152,000. ——Aug. 4th. J. & B. Grier, saw mill, Montreal; loss about $10,000.——Aug. 4th. St. Lawrence Portland Cement Co., Montreal; premises destroyed; loss, $20,000; small insurance.——Aug. 5th. Devine Bros., Killaloe Station, Ont., planing mill; loss, $1,000.——Aug. 9th. Victoria, B. C., Chemical Works; partially destroyed; loss about $20,000; fully insured. ——Aug. 13th. Jenckes Machine Co., Sherbrooke, Que.; damaged to a considerable extent but covered by insurance; business has not been interrupted materially.——Aug. 14th. M. Bristol's wood-working factory, Madoc, Ont.; loss, $10,000; insurance, $1,000.——Aug. 14th. Biette & Co.'s saw mill and cheese-box factory, Chesley, Ont.; loss, $8,000; insurance, $1,000.——Aug. 14th. Miller Bros.' paper mills, Glen Miller, Ont.; damaged to extent of $17,000; covered by insurance.——Aug. 22nd. Steamer "Golden City" burned at her docks, Lakefield, Ont.; loss, $5,000; some insurance.——Aug. 26th. J. H. Still's handle factory and unused pipe foundry adjoining, St. Thomas, Ont.; loss, $50,000 on the handle factory, and $10,000 on the foundry. ——Aug. 28th. The Parmenter & Bullock Co.'s rivet and nail works, Gananoque, Ont.; loss, $30,000; insurance, $12,000.—— Aug. 30th. Some damage was done to the power-house of the London (Ont.), General Electric Co., amounting to about $1,000.——Sept. 1st. Bertram Engine Works Co.'s shipyard, Toronto, damaged to extent of $60,000; fully covered by insurance.

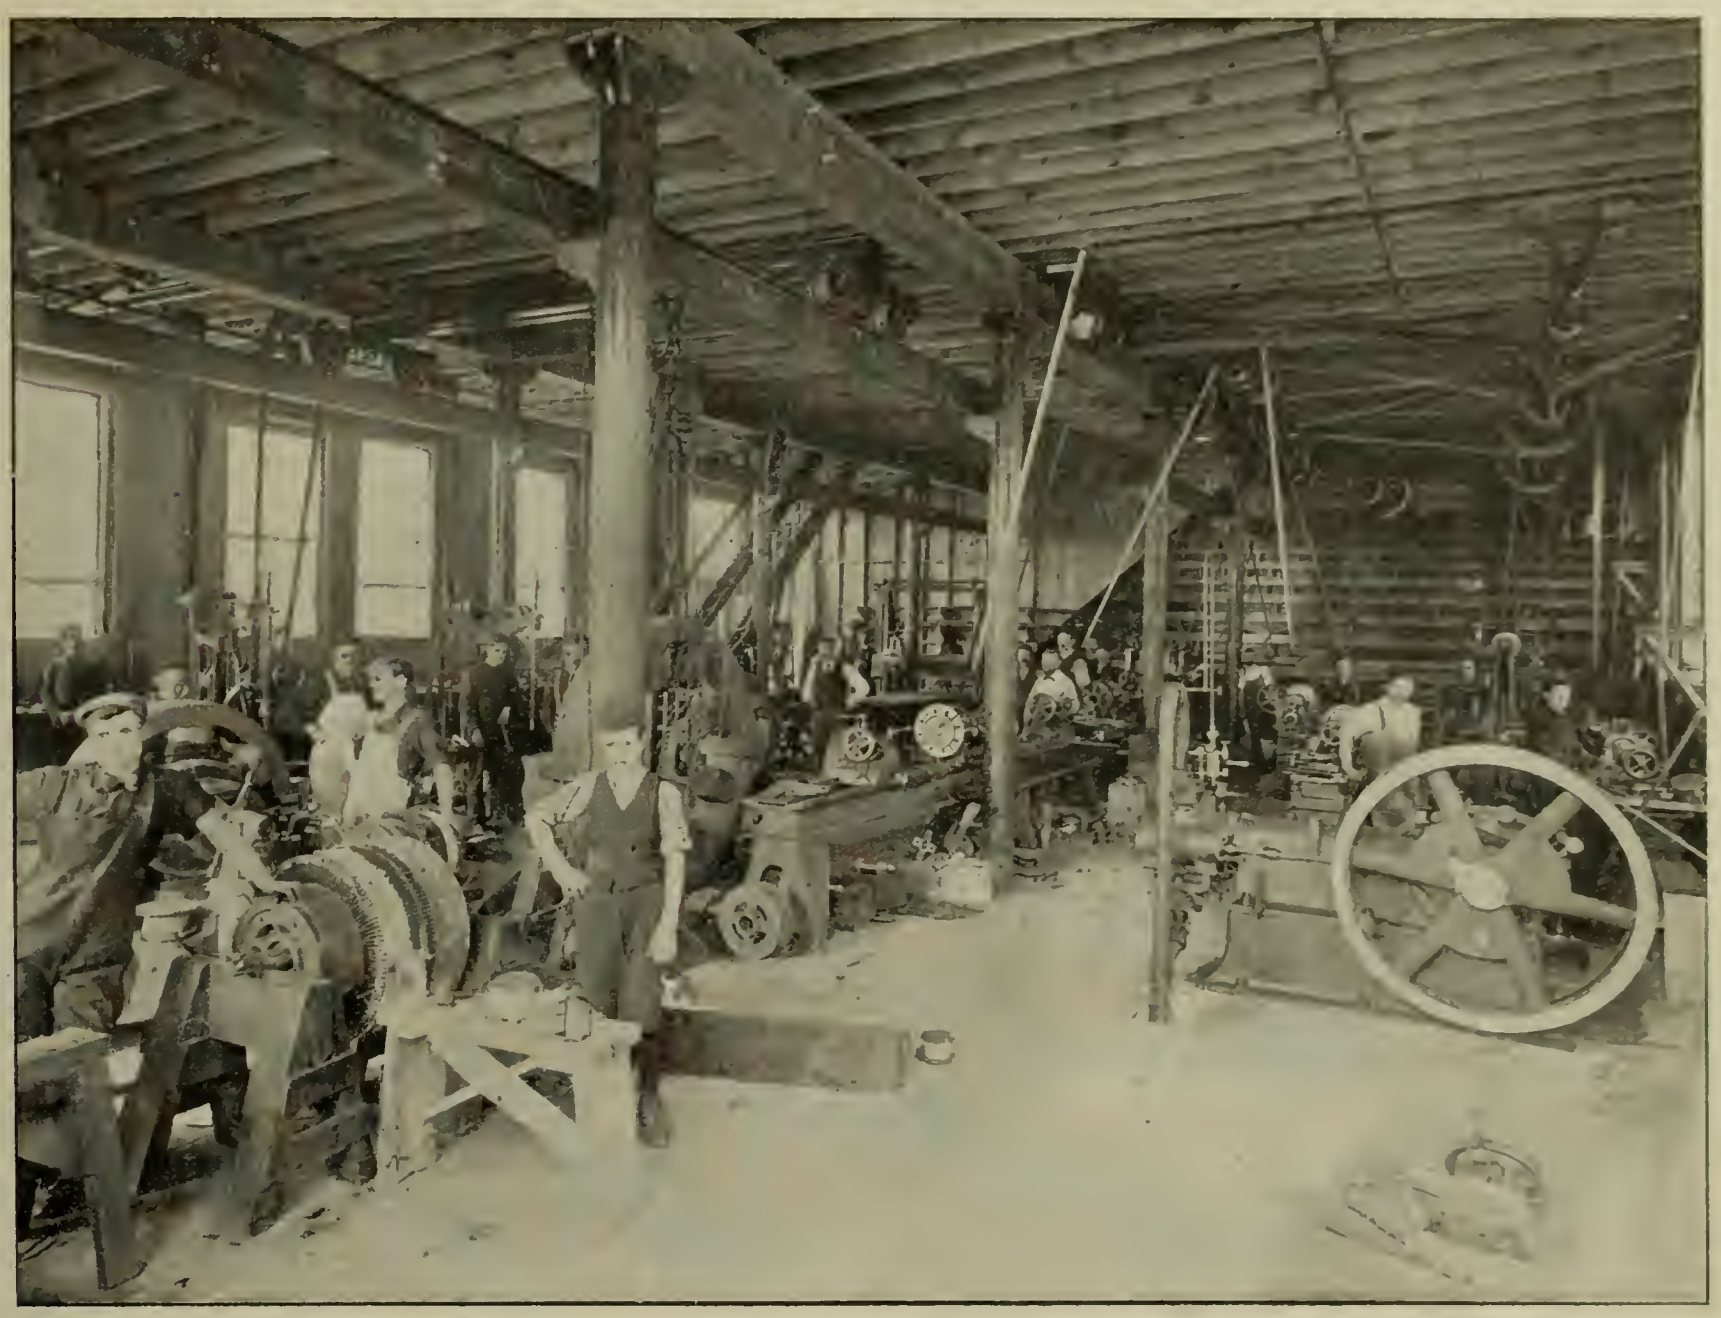
THE TORONTO ELECTRIC MOTOR COMPANY, LTD.

In this issue we present a cut of The Toronto Electric Company's new factory recently completed and now occupied by this thriving manufacturing concern, which started business some six years ago, and which has steadily increased year by year, until now it is one of the leading firms in Canada in the manufacture of the electric machinery and apparatus for lighting and development of power in all its branches. Beginning with electric motors in a comparatively small way the company has added new lines from time to time as demands required, such as belted C. P. dynamos and direct connected generators for lighting and power service in all standard sizes up to 300 k.w.

In March this year this company amalgamated with the Thompson Electric Company, Hamilton, Ont., thus adding that firm's well-known system of automatic arc lighting dynamos and their several types of arc lamps for constant potential, constant current and alternating current circuits, together with all their machinery and special tools for manufacturing. This company's new works are of the most modern and improved type for the class of work upon which it is engaged. The machine shop is supplied with the latest improved machinery and tools, classified and divided into sections, to best suit the convenience in handling the different classes of work; each section being operated by an independent electric motor. The centre of the shop is provided with a 16-ton traveling crane, for its entire length. The arc lamp department is on the second floor, and is supplied with light machinery and special tools and jigs for turning out accurate and standard work. Then comes

the winding room, which is also a separate department, and supplied with necessary lathes, forms, bucks and special appliances for this particular class of work. In the basement is situated the brass moulding department and steam plant, which operates a direct connected unit that supplies current for the power and lighting of the entire works.

The company is now working its factory overtime to meet the demand for its apparatus. Some of the principal orders now being turned out are: Direct connected generators for the T. Eaton Company; complete electric plant for the Verity Plow Company, Brantford, Ont., including a direct connected generator; two incandescent dynamos for the Parkhill Electric Light Company; two 60-light arc dynamos and 80 arc lamps for the Brantford Electric & Operating Company; electric power and lighting plant for the Rat Portage Lumber Company; two 40-h.p. motors for The Mail and Empire Company; 100 arc lamps for the Lachine Rapids Hydraulic & Land Company, Montreal, and numerous smaller orders. Owing to the pressure of business this company will not exhibit at the Toronto Industrial Exhibition this year. Any visitor that will favor the company with a call at the new works, 39 to 45 Pearl street, will be warmly welcomed.



TORONTO ELECTRIC MOTOR CO.'S MACHINE SHOP.

AN UNSANITARY DISCOVERY.

BY W. M. WATSON.

Tourists spending their holidays in Muskoka and other Ontario summer resorts have been considerably exercised on account of offensive odors that have, during the present excursion season, pervaded those districts. We have it on unquestionable authority that large gatherings have abruptly dispersed on account of a sudden passage through the air of a disgusting odor, and which has been stated to be caused by a pest named a stink bug. In the early days of my residence in Canada I was a thorough unbeliever in the power of the animal called a skunk to create a nuisance, but in time proofs came to hand and I was convinced. But not so with the theory put forth to explain the odors that have occasionally contaminated the air, and entered the interior of several of the hotel rooms; before such statements can be taken for granted, at least one of the pests must be caught and produced. I have been engaged to try to give a reliable reason for the foul odors that seem to come, sometimes rather suddenly in the evenings at one of the hotels, and after about 30 minutes time (often less), it completely passes away. It seems only to come after sunset and seldom after the hours of midnight. This almost proves that the cause of the odor either moves in the atmosphere like a bird or the odor is in such large quantities that it moves through the atmosphere in a column, leaving the odor in any place or in any room that it may come in contact with during its passage

From the information I have gathered I find that there are hotels in that district whose sanitary conditions could be improved, and others that have secured the city advantages of a plentiful supply of good water and almost every modern sanitary appliance necessary for the cleanliness and comfort of their patrons, erected with great care, and high class workmanship. It is one of the last named kind that I was called upon to inspect and try to locate the cause of the occasional unpleasant odors. I was the third party that had been called in for the purpose. Each of the previous firms had thoroughly examined and tested the plumbing appliances and drains, and I believe found them smoke-proof and perfect. This hotel had a private sewage disposal works, that seemed to get all the blame, from the managers and attendants. The settling tank was 100 yards from the house, and well covered up, with an air-tight wooden cover, and sand. It had a breather pipe about one foot high and a 4 inch air discharging pipe, 20 feet high, and on account of a suspicion that the foul gases from the tank were discharged into the air through the two pipes, and traveled into the rooms of the house, they had been plugged tight up, but the smell still continued to come as usual. Then the irrigation gravel sewage filter was over another 100 yards away, situated behind a bend and cliff of land, which had also two tall air vent pipes, which would discharge foul air that might travel to the hotel, but it appeared to me rather improbable.

The boarding accommodation for tourists is erected on low grounds near the sheets of water, and this one had high hills on

two sides acting as a boundary line and shield of the narrow strip of water and foreshore situated between them. The sun during the day heated the surface of the land and the walls of the building, the roofs, and to a certain extent, the face of the water. At sunset the atmosphere cooled quicker than the earth, the walls and roof of the building or the face of the sheet of water. This would cause a depression of the atmosphere, making the upper strata of the air descend and cool the warm places, having the effect of reducing the draughts of chimneys, air and soil pipes, and would also let free and distribute any confined gases that might be accumulated in the sanitary apparatus or foul spots near the dwelling. This depression cannot be avoided, therefore it is the duty of plumbers and sanitarians to so erect and put together sanitary appliances in a way that it is absolutely impossible for poisonous gases to generate, and this can be easily done by using reasonable judgment in arranging the soil pipes, the waste water pipes, and the system of drainage.

In another article which I had written before going to inspect this place, and which is published in another part of this paper, entitled "Sanitary excesses," I have described what is needed to aerate soil and waste pipes. In April, 1897, this paper published an article of mine on sanitary appliances, which also explains how to make sanitary waste and soil pipes safe, and what is particularly necessary to be adopted in summer hotels to prevent gases and foul smells from generating in hot weather. On this account these points need not be repeated here.

The hotel of which I am writing has three separate and distinct stacks of soil pipes and sanitary apparatus in each of the three wings of the house. All the soil pipes are joined together and connected with the main trunk drain at one point. The small waste pipes from the baths, the basins, the slop sinks, and even the drinking fountains placed in the corridors of the house, are I believe each and all connected directly with the nearest line of soil pipes, and on this account none of the pipes can secure the proper amount of aeration necessary to prevent the generation of poisonous gases, and when poisonous gases are created they will in spite of every endeavor made to prevent them, escape and contaminate the atmosphere. This statement was fully proved by the exhaustive experiments made by the city of Cologne, see report on page 62 of the July issue of The Canadian Engineer. Now it is easy to fix a first-class sanitary water closet that cannot possibly require a vent or back air pipe. And experiments prove that back air pipes obstruct soil pipe ventilation, and prevent the ventilation which is necessary to keep the interior of the waste pipes clean and properly purified. No small waste pipes serving water fountains, pipes from ice boxes, underground land tiles, or from small baths, wash basins, wash tubs or slop sinks should ever be connected directly to soil pipes or drains, because the small 1½ inch traps are easily dried out by evaporation in hot weather, and all the sooner when a back air pipe is attached, and if they happen to be dried out when a depression of the atmosphere occurs, then the foul gases will enter the rooms in large quantities. And each and all small waste pipes and fittings can be served and made absolutely safe by an easier and cheaper method. Moreover when there is a decided depression of the atmosphere, the vent pipes cannot prevent the water seals in the small traps from oscillation, and when the water in the seals oscillates it usually wastes a portion of the water over the bends, and of course the seal is broken and a passage of air created. It is just possible that the foul odors that invade the apartments immediately after sunset may be accounted for in this way, but it can be proved only by having the smoke machine attached ready and applied at once, when the foul odor is first apparent.

The plumbing of a large summer hotel requiring several sets of apparatus and stacks of soil pipes cannot be made sanitary by exactly the same methods as a place with only one set of appliances, and soil pipe, and they require much more skill and judgment to insure a thorough upward draught and free ventilation through every waste pipe, which is necessary, to remove any risk of down draught currents.

The contract for the seating of Her Majesty's theatre, Guy street, Montreal, has been awarded to the Canadian Office and School Furniture Co., Preston, Ont.

ECONOMY IN THE BOILER ROOM.*

BY CHAS. MOSELEY, ENGINEER, TORONTO INCANDESCENT LIGHT CO.

The fuel expense is one of the largest in the operation of the majority of plants, and any reduction which can be made in the amount of fuel used, while maintaining the same amount of power, is considered a direct gain. The evaporation of more than nine pounds of water per pound of coal is looked upon with suspicion by many, as it is not thought possible to obtain more than this amount in even the best designed and well regulated furnaces and boilers, especially when the firing is done by hand. Mechanically fed boiler furnaces usually give the most economical results. The actual value of the fuel depends upon the way in which it is used fully as much as on any other factor. The heat unit in the coal should be as much as possible utilized, as in one pound of good steam coal there is about 14,000 B.T.U., and about 10,000 of this amount can be utilized, so that 4,000 heat units are lost. The mixture of gases in a furnace depends on the amount of air used. One pound of coal requires theoretically about twelve pounds of air to burn completely. But in practice about twice this amount is required in the boiler furnace. To cause good combustion coal requires a good draft. The gases are consumed near the fire, and the waste gases carry the heat to the boiler on their way to the stack. The boiler ought to have sufficient heating surface, or the hot wasted gases ought to travel a sufficient distance to be cooled down to about 350° F., which temperature is found high enough to produce a good draft in a stack of at least 100 feet high. It is not necessary for me to state the need of keeping the combustion chambers free from the ash that is carried over with the gases to the chambers. In "Smokeless Heating," as published by the General Engineering Co., there is a paragraph entitled, "Competitive vs. Ordinary Test," which is well worth consideration, and I think we might study it with profit. In nearly all plants where a large quantity of coal is burned per day it is a general rule to employ the least possible number of firemen, and it keeps them very busy going from one boiler to the other shoveling in coal the whole time. It becomes more of the nature of slavery than anything else. Is there economy in this way of working? Let us see. In making evaporation tests my experience has been that there is a large difference between ordinary working and working for short spells, as in making competitive tests. When we were making the tests in our plant, while experimenting with shaking grates, the Hawley Down Draft, and the Jones Underfeed, we did so in many different ways. With the Hawley Down Draft in one particular case we fired that boiler as would have to be done in ordinary practice, and the result was certainly a far different one from that obtained when the man stood by this furnace, and attended to it alone. If we treat the fireman as being a naturally lazy animal, I think we will be on the safe side, and you can rest assured that if he has one boiler that will do the same work as another with half the labor, even though the other takes less coal, this boiler will get the most work, and the boiler that should receive constant attention will get very little consideration from him. Between competitive and ordinary working on a hand fired boiler there is actually a difference of 10 per cent. This I have proved repeatedly, and in many cases it has run up as high as 12 per cent. What does this mean? Does it mean that it would pay to have a man at each boiler, and simply attend to it alone? No. It does not: for the simple reason that the less a man has to do the less he is inclined to do, and this applies more to firemen than to any one else. I might state that when we were testing the Jones Stoker we had long periods where we had competitive tests, and others again when we run as in ordinary practice: that is to say, the firemen doing just precisely as he would do if no test was being made. The coal and water, however, were measured in each case. The results were simply astonishing. In the ordinary running test the Jones Stoker would do about 50 per cent. more work and nearly 25 per cent. better economy, whereas with the competitive test the work done on the stoker was about 25 per cent. more, and 15 per cent. increased economy, which bears out the statement that between competitive and ordinary running we have a difference of 10 per cent. Now which is the correct way to look at this matter? Can we obtain

*A paper read before the Canadian Association of Stationary Engineers.

results right along with hand firing equivalent to those obtained during a competitive test? I do not think so, because firemen, as a rule, do not like to be beaten, and will do their very best during a competitive test to do up the other fellow; but at the same time he is wishing inwardly that the test was over so as to get back the old "style" again.

There are many plants in Canada where very good results are obtained if we take the results as made by the engineers into consideration, several of them showing a usual 14 lbs. evaporation per lb. of coal. This you will readily understand is out of the question. There are also a large number where very poor results are obtained, and these poor results are due to several causes, namely: Boilers in very bad order, dirty tubes, poor setting, poor boilers, poor firemen, etc. The man who sells boiler compounds will in all probability say that you do not use enough of his compound; your answer to that is, of course, that there are compounds on the market that are absolutely of no use whatever, and it is simply throwing money away to buy it. I myself believe in a good compound, but will admit that it is difficult to get it. You may get one barrel (the first from a new maker), fairly good, the second of no use whatever, and so on it goes. A good compound is required, and to my mind to-day we have not such a thing. All compound makers state in their advertisements to send on a sample of your water, and they will give you the very compound you require after analysis. You, of course, know what this means—that if one brand does not work they will send another brand of practically the same stuff with another name and try it. Poor boiler and poor setting; this is attributed to trying to keep down the first cost. Pay a good figure for a good boiler and have it set by competent men. Poor fireman; this is in my humble judgment the most important item, and one that should receive much consideration. The fireman may not be poor, but the work that he has to attend to, namely, firing too many boilers, makes him feel that he is neither more or less than a laborer, and as long as he keeps the steam pressure up, no matter how much coal he burns, or how he does it, there appears to be little or no attention paid to him. There are many places where the fireman is never thought of except when the steam pressure goes down, and when such is the case the usual deputation calls upon him to ascertain if he is asleep or not. A good fireman is really a skilled workman, and should be treated as such. He should receive a fair salary, and his employer should bear in mind that any reduction in his pay is far from being a saving. If he is cut down $2 per week you will in all probability find your coal bill increased about $8, and there is not much economy there. How are we to obtain better results in our boiler rooms? I think by putting in machines to do the work, and having men simply to look after them.

EVAPORATION AND THE RAISING OF STEAM IN BOILERS.*

BY P. MACNAUGHTON, MONTREAL.

From the title of this paper you will notice that it is to deal with two things. First, evaporation, and second, the making of steam in boilers. These two actions are often considered as if they were distinctly different, but, I think, it can be shown that the actions are the same in the end, and that they differ only in the way in which the end is reached. In the following remarks it will be noticed that I have tried to show how the natural action of evaporation resembles the action of making steam for power, because it is always instructive to think out how the processes which we make use of every day, compare with corresponding ones in nature. Some have said that it is wasting time thinking of things in this way; if they really think so it would be wasted time, but to others it would be very instructive and pleasurable. I might say that such thoughts would be to them as salt, which though of little use in itself as a food, still makes our food more palatable. Strictly speaking the term evaporation is used to denote nature's method of changing water into vapor, and making steam in boilers is part of man's method of changing water into vapor through an intermediate state familiar to all of us called steam.

The principal actions in nature in which evaporation plays a part, have been noticed by all of us. They are the disappearing of the dew from the grass on a summer morning, and the frost later in the season; the disappearing of water when left standing in open vessels, and on a much larger scale the raising of water from our rivers, lakes and surrounding ocean. Now it is usually admitted that for every action there is a cause, and the cause of evaporation in nature is the heat of the sun. It will make our problem much simpler if we consider, for instance, a bucket of water as made up of a great number of particles of water. That this is the real state of water will be seen at once if we remember that when heat is applied to water it forms steam, which is particles of water visible to the eye, and if heat be applied to steam the particles of steam are divided into smaller particles called vapor, which is invisible.

Atmospheric air, among other things, contains a certain amount of water vapor, and this water vapor as long as the sun is shining is kept suspended uniformly through the atmosphere by the sun's heat. When the sun has set and its heat no longer acts on the atmosphere this water vapor tends to condense to a slight extent and with this condensation it becomes slightly heavier than the other components of the air, and so tends to sink towards the earth, so that in a calm, clear night in summer that part of the atmosphere lying next to the earth contains more moisture than that which is higher up.

That the above statement points out the true state of the atmosphere at night is proven by noticing the land fogs. If we go up a mountain at the first of daylight on a calm, foggy morning we will notice that as we ascend the fog becomes less dense until when we have gone up about four hundred or six hundred feet we will be out of the fog altogether.

This layer of moist air coming in contact with the cool leaves of trees, plants and other vegetation, the water vapor which it contains is further condensed, thus forming dew. I wish it to be clearly understood at this point that the collecting of dew on the leaves of plants is owing to condensation and not to a falling of water as rain. The fact that dew only gathers on the top side of the leaf, and does not collect in our houses even if all the doors and windows are open, is owing to another action which has no bearing on the subject in hand.

Now we come to evaporation or the disappearing of the dew. We have the air in two layers, the moist one lying nearer the earth and the dry one higher up. The sun rising in the sky begins to send his rays of heat earthward, the layer of air lying next the earth becomes warmed first, and owing to the principle that warm air rises, it rises, and the cooler air comes down to take its place next the earth. The air which is now next the earth is dry or lacking in water vapor, so the lack is made up by absorbing a certain amount of water in a state of vapor from the dew on the plants. This circulation has not continued long before all the dew is evaporated. This process of evaporation in nature does not cease when the dew has disappeared, but goes on continually, because there is always a demand for more water-vapor in the air on account of it being partially condensed in the upper regions of air, thus forming first, clouds, and if condensed further the clouds form rain or snow.

We will now proceed to discuss the making of steam in boilers, and then its change from steam to water-vapor, after which we will compare it with the process described above. For purposes of comparison we will turn water into steam in a boiler open to the atmosphere, that is to say, we will raise steam under a pressure of 14.7 lbs. per square inch. In this we are under the same condition as the dew which was turned into vapor under atmospheric pressure also. We will suppose that the boiler which we are going to use is a small circular vessel, say 6 inches in diameter and 12 inches deep, which may be set over a stove hole, and supplied with a steam tight cover somewhat like a piston, by using which we may vary the pressure. We will now put some water in the boiler and place it over the fire, the cover being left off. Now, remembering that water is made up of particles held together by a force (in this case 14.7 lbs. per square inch, or whatever the barometer may read), which must be overcome before we can have steam, we are called upon to exert a force in opposition to the force holding the particles together. We do this by lighting a fire under the boiler. As the fire burns a certain amount of the energy of the coal is transferred to the water, causing the temperature to rise until, when it has reached about 212° F., the coal has transferred enough of its energy to the water to enable it to overcome the atmospheric pressure and water pressure, and

*A paper read before the Canadian Association of Stationary Engineers.

steam is given off. Now, we have water in a state of steam, which is visible to the eye. If we watch the cloud of steam as it rises upward, it will be noticed that it gradually gets thinner and thinner, until at last it disappears from view. What has become of it? We have produced the invisible water-vapor, and it has been absorbed by the air.

The change from steam to vapor took place like this. In a boiler it is the water which lies next the surface exposed to the fire that is first turned into steam. In order to do this the coal must transfer energy to the water to raise not only the atmospheric pressure, but also the pressure due to the depth of water in the boiler. Now when the particles of steam emerge from the surface of the water they are under a less pressure than when at bottom of the boiler, and so contain more heat than is necessary to keep them as steam. This surplus heat or energy causes an expansion or bursting of steam into the smaller particles, which constitutes water-vapor, which is absorbed by the atmosphere.

This last expansion is on the same principle as when we open a try cock below the water line on a working boiler, it is not water which blows out but steam or vapor. We will now sum up these two operations. In the first the heat or energy of the sun does work on the atmosphere, thus setting the air in circulation, and as a result of the air circulating water is absorbed. In the second the heat or energy of the coal does work on the atmosphere, setting free the steam, and at the same time storing in the particles steam and energy, which turns the steam into vapor when it rises into the air. From the above conclusions we see that evaporation, or nature's method of making water-vapor, and the making of steam at atmospheric pressure and its change into vapor, differ only in the two forces that produce them.

In reference to making steam in boilers there are two interesting cases besides the one which we have just discussed, namely, making steam under a pressure greater than the atmospheric pressure, and under a pressure less than the atmospheric pressure. Dealing with the first mentioned case, that is, where the pressure is greater than the atmospheric pressure; this condition can be brought about by fitting the steam-tight cover on the boiler mentioned in the first case and putting some weights on it to the amount of 5 lbs. per square inch. Now, instead of steam being given off when the water is at about 212° F., it will not be given off before the temperature is 226° F. This increase in temperature is due to the fact that before steam can form in this case the coal must transmit to the water enough of its energy to raise 19.7 lbs. per square inch instead of 14.7 as before. This condition of things comes about naturally when boiling water in mines, for as we descend into the earth the atmospheric pressure increases, which corresponds to the added weight.

Lastly and briefly we will consider the making of steam under a pressure less than the atmosphere at sea level. For this we would have to exhaust the air from our boiler by an air pump or other means. Then we would find that steam would be given off when the water is at a temperature less than 212° F., according to the amount by which the pressure in the boiler is less than atmospheric pressure. This shows that as there is less pressure keeping the parts together in this case than in the other two it therefore requires less energy to set the steam free. As an example of this in nature it has been noticed by travelers going up mountains that when they got high up it takes a much longer time to boil eggs than on the plain below, although the water in giving off steam went through the same action in both places. This was due to the fact that at the top of the mountain the pressure of the atmosphere was less than at the bottom, and the water though giving off steam did not contain the heat necessary to boil the eggs. I think if these travelers had been engineers they would have piled some stones on the lid of their kettle in order to save time.

In this case it is interesting to notice that although it requires less heat to raise steam at a high elevation than at the ordinary atmospheric pressure at the sea level we do not gain anything by reducing the pressure, because when we sum up the heat required to raise the steam, and the force required to reduce the pressure below the atmosphere, we will find that it will amount to the same thing as if we were making steam at atmospheric pressure.

OILS FOR THE ENGINE ROOM.*

BY JULIUS M. WILLIAMS, CHEMIST, HAMILTON.

This subject is considered as being important enough to justify considerable attention from engineers, and this paper being much appreciated by the local association, it is by their request read before the convention, and it being considered inconvenient to repeat the full text, it is condensed, and samples of oils and the products of their decomposition are for the same reason not shown. The matter is treated in the following divisions:

1. Relation to the machine, the prime object of oil is to reduce friction, consequent to the effort of the motive force to overcome the resistance of the weight, that is the work of the machine.

2. Nature of the material, fluid, capable of passing between tight fitting surfaces either voluntarily or by mechanical means, non-resisting, especially free from abrading particles, and from corrosive qualities.

3. Possessing sufficient viscosity and specific gravity to be of service; absence of viscosity and low specific gravity being in inverse relation to the strain or weight on the bearings.

4. Nature of the machine and its special conditions.—The points of friction usually called bearings, consisting of two close fitting surfaces, one or both moving, either rapidly or slowly.

The conditions being mainly that of temperature, this suggests the division of bearings into two kinds, hot and cold: cold bearings being considered first as being the earliest in use and embracing the largest number, these are exposed to a range of temperature extending from the average of 100° F. at the top of a room to that of winter weather outside; mechanical contrivances dispose of many of the difficulties met with on account of variations due to temperature.

Hot bearings are few and include cylinders, pistons and cut-offs.

5. The requirements or qualities of the oils to meet these conditions:—

They should be clean, free from abrading substances.

Non-resistant, free from resinous constituents.

Non-volatile, permanent, so that bearings will not "go dry."

Non-drying, free from "gumming" propensities.

Neutral, free from organic or mineral acids, the first due to rancidity, the second to the refining processes.

6. Hot bearings.—To meet the conditions of the very high temperatures of the principal hot bearing, the cylinder oils require to be of high stability and especially free from the substances before mentioned, that is, volatile, resinous, and decomposable ones, owing to the fact that fixed oils decompose at 600° F.; in the presence of steam with the production of fatty acids and glycerine it is evident that oils partly decomposed, rancid, are not desirable in a cylinder.

7. The constitutional nature of oils.—They are supplied by the three kingdoms, animal, vegetable and mineral.

The animal oils are of great variety and from many sources, the principal ones being the meat and fish trades; these include the various refuse handling sections of those trades, whence are supplied vast quantities of oil.

There may be enumerated here in the order in which they predominate the animals whose oils we use in this country: The hog, horse and cattle; of the fish, cod, whale, sperm whale, etc.

The vegetable oils will be familiar as olive, castor, cotton-seed, earthnut (peanut), and are variously the product of seeds, nuts, fruit.

The mineral oils constitute by far the greatest part of the oils in use as lubricants, and are used alone or in combination with oils from the other two sources. Mineral oils possess in their wide range of varieties all the requisite qualities of good lubricants.

*A paper read before the C.A.S.E.

FOR THE FIRST PLACE IN AMERICA.

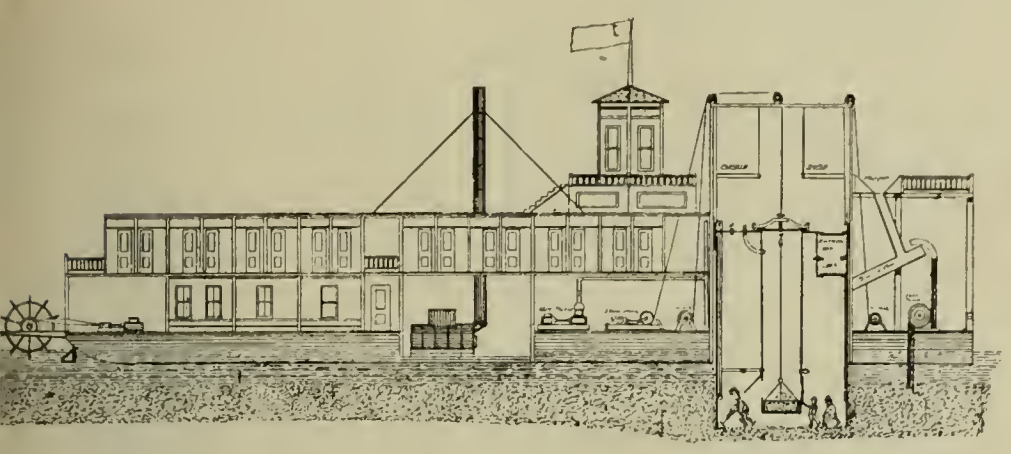
I enclose herewith $1, my subscription for this year, and I am glad to notice the almost monthly improvement in the paper, and congratulate you heartily on the success of your venture. I would like to see The Canadian Engineer competing with The Scientific American for the first place in America.

Yours sincerely, E. ROCHESTER.

54 Rochester street, Ottawa, Aug. 16, 1898.

A NEW GOLD DREDGE.

A number of tests have been made at Vancouver, B. C., recently, of the model of the pneumatic caisson and air lock elevator, invented by Garrison & Wood, and which has been built by them for test purposes there. In every case the tests have proved the invention to be most valuable for the recovering of gold from the bars and beds of rivers and creeks. The model of the caisson and elevator are built into a scow for temporary purposes, but the permanent machine is to be placed



THE CAISSON ELEVATOR IN OPERATION, SHOWING MEN AT WORK IN BED OF RIVER.

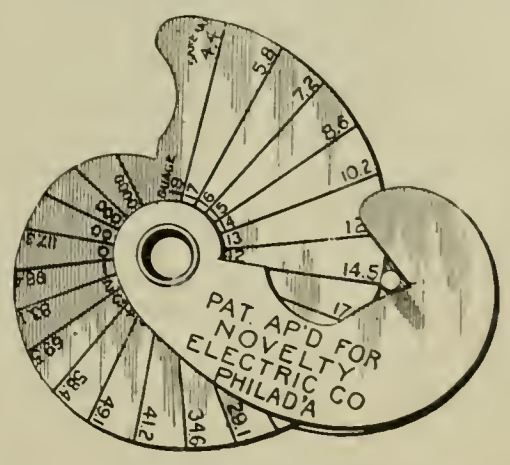
on a sternwheel steamer. The model itself has a caisson 5 feet by 8 feet, but the complete machine will be built of steel, and the caisson will be 10 feet by 20 feet, so as to allow six men to be at work at one time. Entrance to the upper air-closed chamber is obtained through an opening in the top, and when the workmen are all in, the opening is sealed up and the clamps over the opening to the lower chamber are removed, and the bed of the river is reached by means of a ladder. Before the workman goes on board, however, all the water will be removed from all the chambers by air pressure, which will vary from 2½ lbs. to 15 lbs. per square inch according to the depth to be reached. On reaching the river bed, clamps are removed from the elevator shaft and the workmen begin excavating, and shovel the dirt into a bucket in the elevator. When the bucket is full the elevator shaft is closed tight, a signal is given, and the shaft is opened at the top, the bucket is hauled up and its contents emptied on to the dump. It is then lowered into the shaft, which is again hermetically closed at the top, a signal is given and the fastenings below are removed, so that the whole process can commence again. C. C. Bennett, of F. C. Innes Co.'y, Ltd., Vancouver, B. C., is the agent of the invention for Canada.

REFRIGERATING MACHINES.

A correspondent of Fairplay, London, writes: As a result of the recent extensive additions J. & E. Hall, Limited, have made to their works at Dartford, Kent, which, by the way, is the third time this has been necessary during the past few years, I hear that they have been turning out refrigerator machines on their patent carbonic anhydride system for the last four months at the rate of fifteen per month, that is to say, a total of sixty machines in four months. This is a result that they may well be proud of, as many of the machines were of large size, such as those for Houlder Bros. & Co.'s two latest ships, which have a capacity for over 2,000 and 3,000 tons weight of meat respectively; also those for the White Star Line for their S.S. Nomadic and Tauric for the carriage of chilled beef; machines for the United Steamship Company of Copenhagen for the carriage of about 900 tons of butter and bacon in each ship; and for Thos. Wilson, Sons & Co., in the same trade. The British Admiralty have had several more machines from Messrs. Hall, and the new Japanese battle ships have been fitted by them. For the carriage of fruit and preserving provisions, etc., Messrs. Hall have executed further orders for the Union Steamship Company and Donald Currie & Co. Other machines have been supplied to the Oriental Steamship Company of Japan, the Nippon Yusen Kaisha, Baron Rothschild's new twin-screw yacht, the Atmah, the Russian Volunteer Fleet, and many other vessels. They still have in hand orders for no less than 75 machines, either fitting or to be fitted on board ship, besides a large number of machines for land purposes, which comprise almost every trade for which refrigeration is required. It is interesting to note that J. and E. Hall have fitted and have on order for the largest steamship companies no less than nine installations each for two of those companies, also orders from seven other companies that run into from four to six installations apiece, and orders for ten, seventeen, eighteen, twenty-three, twenty-eight and thirty installations respectively, for other companies. A description of some of these machines will appear in another issue of The Canadian Engineer. The London office of the company is at 23 St. Swithin's Lane.

HOW TO USE THE ELECTRIC WIRE GAUGE.

Place the wire in the V-shaped opening between the movable arm and the edge of the gauge. Move the arm around until the wire is tightly bound against the edge. On the front of the gauge the figures above the short, square shoulder, near the centre, show the American (B. & S.) gauge of the wire. The figures on the outer edge of the gauge on small line, show the amperes the wire will safely carry before heating to 30 degrees above the temperature of surrounding air. On the back of gauge the ohms resistance is given of a foot of copper wire, of any size, as shown by the gauge. To find the resistance of a foot of iron wire, multiply the resistance of a foot of copper wire by seven (7). To find the resistance of a foot of German silver wire, multiply the resistance of a foot of copper wire by thirteen (13). To find the number of lamps a wire will carry: Bear in mind that a 50-volt lamp takes 1 ampere, a 75-volt lamp ¾ of an ampere, and a 110-volt lamp ½ an ampere of current. From the gauge, get the size of wire and its safe carrying capacity in amperes. The wire will carry as many lamps as the current of one lamp of a given voltage is contained in the ampere capacity of wire, as shown by gauge. Example.—The safe ampere capacity of No. 12 copper wire B. & S. Gauge is 14½ amperes, and one 110-volt lamp requires ½ ampere of current; therefore, $\frac{14\frac{1}{2}}{\frac{1}{2}} = 29$, the number of lamps a No. 12 B. & S. gauge, copper wire, will carry. To find the size of wire required to carry a given number of lamps, at a given distance, at a given loss.—Taking the formula as stamped



on arm gauge: Let V represent the volts loss, C represent the total amperes and D represent the distance in feet (both ways). Example.—Desiring the size of a feeder wire that will carry 20 amperes at a loss of 10 volts, 400 feet (800 feet both ways). V = loss in volts, which, in this case, is 10; C = total amperes, which, in this case, is 20; D = total distance in feet, both ways, which, in this case, is 800. Therefore, $\frac{10}{20 \times 800} = \frac{10}{16{,}000}$ .000625, the resistance of one foot of copper wire. Having this result, place the square shoulder of the gauge-arm on line with the nearest resistance to said result that is found on the gauge, and the square shoulder on the reverse side will indicate the B. & S. copper wire gauge desired; in this sample case, it will be found to be No. 8 wire. For sale by Aikenhead Hardware Co., 6 Adelaide street East, Toronto.

James Stewart & Co. are at work on the foundations of the new bridge to be constructed across the Niagara River at Lewiston.

The St. John, N. B., Globe says: The building of the Cushing Sulphite Pulp Company's mill is now an assured thing, for one English paper maker has taken three-quarters of the stock and more than one-half the remainder has already been subscribed by local capitalists.

METAL IMPORTS FROM GREAT BRITAIN.

The following are the sterling values of the imports of interest to the metal trade from Great Britain during July and the seven months ending July, 1897, 1898 :—

	Month of July.		Seven months ending July.	
	1897.	1898.	1897.	1898.
Hardware and cutlery	£5,825	£2,372	£37,755	£14,290
Pig iron	942	928	3,807	7,105
Bar, etc.	786	502	5,799	7,239
Railroad	17,368	8,190	37,654	23,007
Hoops, sheets, etc.	8,313	7,843	31,003	24,466
Galvanized sheets	6,083	8,294	25,458	32,461
Tin plates	5 989	12,123	94 942	85,598
Cast, wrought, etc., iron	1,943	2,295	19,277	18,637
Old (for re-manufacture)	1,080	499	2,577	3,574
Steel	6,099	5,040	29,537	32,897
Lead	3,699	4,170	10,959	16,460
Tin, unwrought	345	1,638	10,179	12,423
Alkali	2,289	3,587	17,649	24,597
Cement	1,934	2,270	8,489	12,222

THE USE OF IMPROVED METERS IN ELECTRIC LIGHTING.

It has been found by experience, it is stated, that a central lighting station can supply 30 per cent. more customers on the meter than on the flat rate. This 30 per cent. really represents wastefulness, which is inherent in the nature of the average customer, and the flat rate. The investment in meters, and their proper care, makes the plant equivalent to one 30 per cent. larger. A central station which is in the electric lighting business for the profits on its investment can easily realize the great advantage in the use of meters. That many small villages and cities make but a small profit, or the income only sufficient to pay actual running expenses, is not surprising, in view of the waste and extravagance of the flat rate. These same stations may, by proper and economical use of meters, be made profitable. It is not necessary to point out the evils of the flat rate; but it is self-evident that many customers never take the trouble to turn out all or part of their lamps, and in places where the plant gives all-night service the lamps are left burning all night. A fallacy in flat rates is the basing of charges on 50-watt lamps. A 50-watt 16-c.p. lamp is somewhat of a rarity in the market, 60 watt being about an average, and many lamps are used taking more even—70 or 80-watts. In most small stations the voltage is kept above what the lamps were made for; even in the case of a 50-watt lamp the consumption will be higher. It has been found that most small stations, if they use 50 volts, keep the voltage at 55 or 60. These wastes are impossible to avoid in the flat rate. A meter measures the actual consumption of current. The central station gets paid for actual service given the customer, and it behooves the consumer to use his lights in the best and most economical way.

New Scheefer watt-meter for alternating current has been devised to correct various faults which were in the Scheefer meter, which has given such good results, states the Packard Electric Company in a recent circular. As will be noticed, the meter is round and has a rubber band placed around the circumference, over which is placed the other case. This rubber band should always be used, as it makes the meter perfectly dust and bug proof. It has been found that meters with cases of ordinary fitting are hampered with dust and dirt; and with such cases it is impossible to keep meters correct, necessitating frequent overhauling and cleaning. The Packard Company's new meter, if the case is properly put on with the rubber band, is perfectly air tight, and gives an assurance of its permanency. The binding posts will be seen to be insulated in a thorough manner, ordinary holes not being depended upon. The holes in the binding part are closed on end and insulated by hard rubber, making it impossible that anything can get through the post; and also making it unnecessary to tape or plug any holes. The moving parts are extremely light—at the same time not too delicate. The iron circuit in the magnetic system is practically a closed one, preventing stray lines of force from acting on other parts of the meter, and is therefore unaffected by outside influences. This closed circuit gives the maximum effect with the minimum energy possible in construction, the shunt winding taking about 1-3 to 1-2-watt on 15,000 alternations, and not exceeding ½ to ¾-watt on 7,200 alternations. This meter is also said to be correct on inductive loads, and therefore can be used on fan motors or induction motors, arc lamps, etc.

Industrial Notes.

Joseph Carrington is building a large addition to his tannery at Kingston, Ont.

Mayor Roy, of Levis, is negotiating with Montreal capitalists for funds for an aqueduct for that town.

Dr. Bryce of the Ontario Board of Health has reported that additional sewers are needed at Kincardine, Ont.

The Ontario Silver Co., Humberstone, Ont., has installed a second gas engine recently; the new one being 40 h.p. capacity.

H. Mooers & Co., of Kingston Ont., are about to build a new flour mill, which will be run in connection with their elevator.

Lancaster, Ont., village corporation is looking for some industry or industries to locate in the town. Good inducements are offered.

It is said that a shoe factory is soon to be established at Fredericton, N. B.; $20,000 of the required capital has already been subscribed.

McDonald & Allen, manufacturers of door knobs, Kingston, Ont., have closed out. The plant has been bought up by Mr. Spencer, who will reorganize the business.

M. Fauteux has the contract of building the new hospital at Sault Ste. Marie. The work is estimated to cost $20,000. and is to be completed by the 10th of January, 1899.

Engineer C. H. Mitchell, Niagara Falls, Ont., writes that the town is about to construct 8,700 lineal feet of 6, 8 and 10 foot concrete and brick walks, together with stone curbing and crossings.

The Peterboro, Ont., Light & Power Co., is about to commence the erection of a large water power station. The new station will cost between $30,000 and $40,000, and the company expects to develop about 2,000 h. p.

The contracts for the new iron bridge over the River Raisin at Lancaster were let, and Williams & Fallon, of Cornwall, Ont., have commenced work on the abutments. The Dominion Bridge Co. will supply the structural work.

The Ontario Board of Health has given Fort William, Ont., permission to take the supply of water from the Kaministiquia River three miles above the town, provided that the sewer outfall should be a quarter of a mile from the mouth of the river, emptying into the bay.

It has come to our knowledge that certain bogus or fraudulent firms in Holland are entrapping Canadian manufacturers in the iron trades, and we would sound a note of warning that no goods be shipped without security in some form. Could not our boards of trade look into the matter ?

The demand for Clappison's magnesia sectional covering has been so great that it has become necessary to greatly enlarge the factory at Hamilton, Ont. Another story and a new engine room—an entirely new front—new machinery, etc., having been added. This goes to prove that a really good article, once used, is sure to be appreciated.

The hydraulic jacks recently shipped to the Intercolonial Railway Co. by the Lancaster Machine Works, are reported to be first-class articles giving great satisfaction. These jacks, although retaining the main original features of the Tangy jacks, have several improvements that place them ahead of all other makes. They are made in all sizes by the Lancaster Machine Works, Lancaster, Ont.

In the paragraph last month referring to the transfer of certain oil properties to the Bushnell Co., Ltd., of Sarnia, omission was made of the transfer of the National Oil Co., of Petrolia (owned by John Macdonald), at $65,000. The price at which the Empire Oil Co., of London (owned by J. R. Minhinnick), was transferred was stated to be $4,000 instead of $28,000.

The Athens, Ont., Methodist congregation will build a new $10,000 church.

Newmarket, Ont., has carried a by-law to give $5,000 to the Office Specialty Manufacturing Co. to extend its buildings.

The contract for the Ashburnham waterworks system has been awarded to McQuillan & Co., of Toronto, at $6,295.

The new ranges of the Dominion Rifle association at Rockcliffe, Ottawa, are provided with acetylene gas lights instead of electric lights.

J. E. Webb, who was contractor for the masonry on the Union station, Toronto, is building a large generator house for the Consumers' Gas Co., Toronto.

Jno. Galt, C. E., Toronto, has made preliminary surveys and examinations at Stayner and Bolton, Ont., for the proposed installation of waterworks in those towns.

The matter of the contemplated bonus to the proposed rolling mills in Belleville, Ont., will not come before the ratepayers for some time, as a great deal of opposition has recently developed itself locally.

Dr. P. H. Bryce, secretary of the Ontario Board of Health, reports that the residents of Niagara-on-the-Lake are taking the sewerage question into serious consideration, and hope in a short time to have a modern system in operation.

Alex. P. McKee, proprietor of a glass factory in Anderson, Ind., was recently in Hamilton, Ont., with a view to establishing a factory there. The report that the Diamond Glass Company proposed to move to Toronto was the cause.

In St. John, N. B., the city engineer is carrying on the annual clearing of the city water mains. In the leading Ontario cities when the water mains become choked up with sediment they lay new and larger ones.

The waterworks just completed in Mount Forest, Ont., were tested August 30th, and found entirely satisfactory. The work was carried out at a cost of about $30,000 by Clark & Connelly, contractors, Toronto, upon plans prepared by Jno. Galt, C. E., Toronto.

D. S. Collins, manager of the Fossil Flour Company's mills at Bass River Lake, Castlereagh, Londonderry, N. S., is pushing the works, and the product that is now coming from the mill is said to be most satisfactory. The mill is turning out from 10 to 13 tons of refined silica every day. It is brought over the Pole Railway to the wharf at Bass River for shipment.

The Brockville Pork Packing Company has been organized with W. H. Comstock as president; Mr. Packingham, treasurer; Mr. McLennan, secretary, and E. C. Manning, formerly of Dublin, Ireland, as manager. The buildings for the new company are being got into shape, and the factory will soon be running.

Last month an article appeared in the columns of The Canadian Engineer describing the Sterling Hack Saws, which are a great labor-saving device; the makers' name and that of the parties selling same in Toronto were omitted. The Diamond Saw & Stamping Co., of Buffalo, manufacture these goods, and samples will be sent free and prices quoted on same by Aikenhead Hardware Co., 6 Adelaide street east, Toronto.

The Britannia Co., of Colchester, Eng., have sent us a neat souvenir in the form of a nine inch rule with one edge beveled to form a letter opener. This company manufactures various specialties in tools, and has just issued leaflets descriptive of their lathes with turret rests and capstan rests, for milling machines, and headstocks for the same, dividing appliances, engineers' vices, turret screw cutting lathes, boring machines, shapers, etc.

The General Engineering Co., of Toronto, Ltd., are prosecuting an action, taken out last July, against the Dominion Cotton Mills Co., of Montreal, and the American Stoker Co., for infringement of patents. The statement of claim sets forth that the plaintiffs are owners of patents granted in 1892 and subsequent years for improvements in boilers and furnaces and for mechanical stokers, known as the Jones Underfeed Mechanical Stoker, which patents the defendants have infringed. Damages are sought for these infringements, and an injunction is asked for restraining the defendants from using such mechanical stokers, etc. The action is taken in the Exchequer Court.

A bonus of $2,500 is offered for the erection of a 50-barrel flour mill at Carnduff, Assa.

D. W. Karn & Co., Woodstock, are erecting a $3,000 addition to their organ factory.

Charters Smith, Durham, Ont., has his foundry, which was burned down some time ago, in operation again.

Geo. H. Hees & Co., Toronto, window shade manufacturers, have taken out a building permit for a three-story brick factory to cost $9,000, and a three-story brick warehouse, beside the factory, to cost $7,000.

Oshawa, Ont., has instructed Jno. Galt, C. E., to make preliminary surveys and estimates for a system of water supply and sewage disposal for the town, to cost about $100,000. The water supply is to be by gravity from springs in the Oak Ridges.

The difficult work of taking down the old Victoria bridge, Montreal, is being made somewhat easier by the use of pneumatic machines to cut the old rivets. The Ontario Rolling Mills Co., Hamilton, Ont., has bought the material of the former structure.

A great many elevators are being built in the Northwest this season. The Northern Elevator Co. has ten elevators under construction at the following points: Oak River, Varcoe, Pettypiece, Cypress River, La Salle, Starbuck, Elm Creek, Somerset, Swan Lake and Union Point, Man. Each of these will have a capacity of 30,000 bushels, and a few others will be erected later on in the season. When those mentioned are completed the Northern Elevator Co. will have 102 elevators in the province and Territories. Besides the five to be built for the Lake of the Woods Co., E. J. O'Reilly has about completed an elevator for the Richardson Grain Co., of Kingston, at Sydney, to replace the one destroyed last winter. The Manitoba Grain Co. will also erect a number, and it is understood the Dominion Elevator Co. will add to their storage capacity. Bready, Love & Tyron will spend about $50,000 in erecting elevators at thirteen or fourteen provincial and Territorial points.

The Dodge Manufacturing Co., Toronto, Ltd., has been incorporated and will carry on the business hitherto conducted by the Dodge Wood Split Pulley Co., with works at Toronto Junction, and warerooms and city offices at 74 York street. The Dodge Manufacturing Co. will continue to manufacture the Dodge Wood Split Pulley. It will also do a general foundry, engineering and machine shop business, making a specialty of power transmission machinery, such as shafting and pulley equipment, jack shafts, floor stands and friction clutch pulleys. The firm will also make a speciaity of grain elevator machinery and rope driving. The Dodge Co. has every facility for turning out high class work quickly, and are prepared to make plans and submit estimates and give information on all kinds of special machinery. The company issues a 270 page catalogue which will be mailed free on application.

Freeman C. Coffin, engineer to the city council of Carlottetown, P. E. I., prepared the plans adopted by the Sewer and Water Commissioners for a complete sewage system for the city. The system decided upon is the common separate water carriage system with intermittent discharge into the sea by means of a reservoir, cast iron pipe and the channel of the Hillsborough. There will be a pumping station at a low point both on the east and west sides of the central high gravity area, which location of pumps will altogether obviate the use of siphons and at the same time carry away the sewerage from the lowest levels to the eastern and western portions of the city. From each of the pumping stations already mentioned, and the tank connected therewith, the sewerage will be pumped through a cast iron pipe to an elevation of about 20 feet on the high gravity area, where it will enter an earthenware pipe of a large size to enable it to flow freely with the other sewerage passing at the same level into the outlet reservoir. It is proposed to erect an outlet reservoir at or near the head of Pownal wharf, 40 feet by 90 feet inside measurement. This reservoir will be covered with an arch roof of concrete, to effectually guard against the escape of any foul odors. From this reservoir, running between Pownal and Connolly's wharves, there will be a 20 inch cast iron outlet pipe of the approximate length of 700 feet, or until it reaches well out into the channel of the Hillsborough.

Parry Sound, Ont., has ordered a rock crusher.

The village of Gatineau Point, Que., has voted to establish water-works.

The contract for the new breakwater to be constructed at Goderich, Ont., has been awarded to Sneeth & McGillicuddy.

J. A. Savoie, box manufacturer, Brompton, Que., will move his factory to Sherbrooke, where he will employ about fifty men.

J. E. Wilson, St. John, N.B., has received from the C.P.R. the contract to furnish 3,000 steel buckets for the new elevator conveyors.

Mayor Andrews, of Winnipeg, has gone to England to float a bond issue to provide for the construction of a city water-works system.

It is proposed to erect the new dynamite works of the Ottawa Dynamite Company on a site between the Ottawa river and the Richmond road.

The Waterloo township, Waterloo County, Ont., by-law to raise $9,000 for the purpose of replacing the bridges swept away, was carried last month.

A by-law to provide $40,000 for waterworks purposes, repealing the by-law for $35,000 already voted, was defeated in Fort William last month.

Voting on a by-law for the establishment of a waterworks system, took place at Prescott, Ont., Aug. 18th, and it was carried by a majority of 124.

Berlin, Ont., has an old hand fire engine that has a history. It was purchased on December 19th, 1857, from George Penny, of Montreal, for £219 9s. 11d.

The contract for the building to be erected on the site of the old City Hall, Quebec, has been awarded to Joseph Gosselin, of St. Joseph de Levis, at $75,000.

A bylaw to raise the sum of $30,000 for the purpose of erecting new municipal buildings, in place of those burned last November, was carried at Stratford recently.

Wm. Thompson, expert of the Caledonia Iron Works, reports that he is making rapid progress with the installation of the waterworks plant at Rat Portage, Ont.

A Dominion charter is asked for a company to build a general traffic bridge over the Ottawa from a point in Ottawa city, between Bank and Kent streets, to the city of Hull, Que.

Recent fires in Montreal have caused an agitation for fire tugs, which are necessary to the protection of a harbor, and are in use in all the chief harbors of the United States.

An elevator is being erected at the linseed oil works, Winnipeg, and considerable new machinery has been installed in the works, increasing the capacity and efficiency of the industry.

The acetylene gas plant installed this summer in the Algonquin hotel, Stanley Island, Ont., by the Hamilton Acetylene Gas Machine Co., is giving complete satisfaction. There are 150 lights.

Dickson Bros., iron founders and machinists, Campbellford, Ont., have been awarded the contract for the steel bridge across Crow River, eight miles north of Campbellford, for $1,900.

The People's Light & Power Co., Halifax, N. S., has added to its plant by purchasing through the Halifax office of the James Cooper Mfg. Co., another 50-h. p. Lidgerwood hoisting engine.

The contract for the re-building of the portion of St. Bernard's Convent, Antigonish, N.S., destroyed by the recent fire, has been awarded to Angus McDonald & Son, Truro, N. S. Their tender was $11,342.

The W. C. Edwards Co., Ottawa, is erecting a retort for the manufacture of calcium carbide gas from sawdust and limestone. A description of the process will appear in an early number of the CANADIAN ENGINEER.

The Reids of Montreal have laid before the Newfoundland Government their plans for the erection of a pulp mill at Grand Lake. It is to be a company with a capital of $2,000,000, which has already been subscribed. The mill is to have the capacity of 162 tons of dry pulp per day, and for this purpose will use 450 cords of spruce daily.

The assets of the Cascapedia Pulp & Lumber Co. were sold at auction recently. R. H. McLelland, of St. John, N.B., bought the saw mills and machinery for $15,000, and the Salmon River timber limits for $2,900.

An order has been placed with the James Cooper Mfg. Co., Ltd., Montreal, by the Canadian Construction Co., Farrans Point, Ont., for two of the Lidgerwood type double cylinder double drum hoisting engines, complete with boilers.

Architects are asked to compete for plans for a Presbyterian church, Windsor, N. S., seating capacity 500 or thereabouts, and of schoolroom 250, of wood, to cost not more than $12,000 fully finished, including lighting and heating; if of stone, to cost not more than $16,000, finished, lighted and heated.

The Nova Scotia Glass Co., South Trenton, N. S., has sold its works and plant to the Diamond Glass Co. The works have been closed since 1892.

Later reports show that the damage to the works of the Jenckes Machine Co., at Sherbrooke, Que., by fire on the night of the 13th of August, was very much exaggerated. The fire was confined to the machine shop building, and the other departments, foundry, boiler shops, etc., were in operation as usual on the following Monday. A few days later a portion of the machine shop was started up, and the whole was in running order in a very short time. The patterns, drawings and office records were preserved practically intact, and all orders for work are being accepted as usual. The principal item requiring replacement is the roof of the machine shop; this, however, is well under way. The whole of the work is being pushed with much energy, and the numerous orders in hand will suffer comparatively slight delay.

The International Correspondence Schools, of Scranton, Pa., have decided to place representatives in the Canadian field, and will in a short time open an office in Toronto for the extension of their business. This is an institution that wants the consideration of all steam engineers, as they aim to give a technical education in engineering to all who will study. For starting as they do at arithmetic, they are prepared to teach anyone who can read and write. No previous knowledge of the subject is required, and anyone who will study can learn. Two of their representatives, Geo. Carruthers and J. E. Taylor, have been in Toronto for some time, and are very much encouraged by the interest shown in the schools. Their address at present is 226 Jarvis street, and they will be pleased to answer any enquiries, personally or by mail, regarding the various courses taught. They have some 1,400 students in Canada, and will be glad to give the names and addresses of any of these for reference.

Marine News.

A. Nichols, of Carleton Place, has bought a steam yacht.

The Chateauguay and Beauharnois Navigation Company, Ltd., capital $9,100, has received a Quebec charter.

Wm. Thomson & Co. are negotiating for the purchase of a steamship of 5,800 tons dead weight to be ready for delivery in November, to replace the Arbela.

The steamer "S. L. Tilley" has come out of the Kingston dry dock, where she has been undergoing extensive repairs. She has started for the upper lakes.

M. J. Hogan, of Section 12, Soulanges Canal, has placed an order with the James Cooper Mfg. Co., Ltd., of Montreal, for three of the latest type Sergeant drills.

M. A. Cleveland, contractor, of North Channel, found that he has considerably more work than anticipated, and has put in three more Ingersoll-Sergeant drills.

The steamship Leuctra Company has applied for a New Brunswick charter to own and sail the steamer Leuctra; chief place of business, Rothesay, N. B.; capital, $160,000.

The engines have been placed in the new C. P. R. steamer Queen City, and carpenters are busy finishing her deck house and fittings. She will be ready for service in about a week.

The machinery has been taken out of the steamer Carleton at Carleton Place, Ont., and the hull is to be fitted up as a barge for carrying passengers in tow of the Commodore.

The steamer Macassa was run into recently by the Ella Merton, owned by Elias Rogers & Co. The Macassa had the front part of the upper deck and the wheel house demolished. The schooner suffered the loss of her sails and jib-boom.

The Harbor Commissioners of Montreal invite offers furnishing them with land suitable for the site of a dry dock. The land must be on the north bank of the River St. Lawrence, between the Sugar Refinery and the Longue Pointe church. Lots offered must have a depth of not less than 600 feet from the boundary of the harbor lands to the Quebec Turnpike road, the breadth required being about 600 feet.

C. Giguire, under contract with the corporation of Quebec, has just built a large pontoon for the Champlain market wharf, for $9,186. This pontoon, the third of the series of new ones for the market and ferry boats, plying to the city wharf, is like the other two which were built in 1896 and 1897, 120 feet in length, 40 feet broad and 8 feet high or deep, conformably to plans and specifications prepared by C. Baillairge, city engineer, and under his superintendence and that of Foreman Verrault.

The K. M. T. & T. Co. and the Lake Bennet & Klondyke Navigation Co., have amalgamated, at least so far as their transportation business is concerned. Hereafter the latter company will have charge of all transportation matters, the steamer Amur, owned by the K.M.T. & T. C., being run by them in connection with their river steamers Oro, Nora and Flora, plying between Dawson and Bennett. The K. M. T. & T. Co. taking the offices in the Five Sisters Block and the Bennett Lake & Klondyke Company removing to the Government street offices.

The Esquimalt Marine Railway, Ltd., has sold out the plant and ship building business to a company which has been formed under the name of the British Columbia Marine Railway Co., Ltd. The new company, which has been incorporated with a capital of $200,000, has taken over the business as a going concern, the sale dating from July 27th. In addition to the large plant at Esquimalt which is capable of handling ships up to 2,500 tons, the new company intends to put up a smaller plant in the inner harbor for handling smaller vessels and will extend its business too to Vancouver, where it has already secured a site.

The new slip docks at Port Stanley, Ont., the contracts for which were awarded by the Lake Erie & Detroit River Railway Company late in May, will be completed and ready for use in a few days. The contracts called for their completion on Aug. 1, but unavoidable delays prevented their being finished in that time. The docks are being constructed immediately to the west of the light-house piers, and with the tracks and grading of the approaches, they will cost in the neighborhood of $55,000, the estimated cost of the docks alone being $45,000 and of the approaches $10,000. The contractors are the Hamilton Bridge Company for the iron work, and Babcock & Flook, Windsor, Ont., for the woodwork.

Railway Matters.

The new I. C. R. station at Moncton, N. B., was opened to the public, August 1st.

Trains are now running on the New York and Ottawa Railway between Ottawa and Cornwall, Ont.

Track laying on the Swan River extension of the Dauphin railroad is now going on, about 35 miles of grade being ready.

The new Grand Trunk offices in Montreal are to be a magnificent structure, the largest railway offices in the world. R. A. Waite, Buffalo, is the architect.

Mackenzie & Mann let to E. F. Farquhar, Toronto, the first 25 miles of work on the Ontario & Rainy River Railway. Locating parties are already in the field. Thomas White is chief engineer.

At a recent meeting of the Board of Directors of the Canadian Pacific Railway Company, dividends of 2 per cent. on the preference stock and 2 per cent. on the common stock for the half year ended 30th June last were declared, payable 1st October.

It is stated that the proposed railway from Brandon to Deloraine will be built this year, with a spur to the coal district south of Deloraine, where it is said a plant for mining coal will be put in.

Casper Braun, contractor, Berlin, who erected the G. T. R. depot in that town, has been asked by the Grand Trunk authorities to tender for the erection of a large round-house at Sarnia, to house 30 engines in.

The Brandon Southwestern Railway survey party has been gradually working its way north to Brandon, and has now reached that town. It is expected that the road will connect with the Great Northern at Bottineau, U. S.

With a view to completing the double track on the Montreal and Brockville section the Grand Trunk Railway authorities are at present engaged in widening the bridges at St. Annes and Vaudreuil, in order to place an additional track on each.

Work is progressing satisfactorily on the Restigouche & Western. A large force of men is employed under C. L. B. Miles, engineer in charge. It is expected that ten miles of rails will be laid early in October, and a second ten miles graded The first sod was turned August 12th.

The Brotherhood of Locomotive Firemen will, this month, celebrate in Toronto its twenty-fifth anniversary, and the sixth bi-ennial convention, beginning on the 12th. The Locomotive Firemen's Magazine has issued a handsome illustrated supplement showing a number of views of Toronto and portraits of the officers.

Application will be made at the next session of the Ontario Legislature for an Act to incorporate the Haliburton, Whitney & Mattawa Railway, to construct a railway from a point at or near the present terminus of the Grand Trunk Railway at Haliburton, to a point on the Ottawa, Arnprior & Parry Sound Railway, at Whitney, Ont., and in a northerly direction to Mattawa on the Ottawa River, with power to equip and operate it by steam or electricity.

The Grand Trunk Railway is making considerable additions to its rolling stock at the present time. It has just received from the Pullman Company twenty passenger coaches, which will be used on the western division of the road. Mammoth engines are being specially purchased to haul these new coaches. The company is now busy building 500 box cars in its shops at Detroit, and also 250 new stock cars.

E. C. Walker has been elected president and managing director of the Erie & Huron Railway, S. A. King vice-president, and J. H. Walker treasurer. John Forman remains secretary The following appointments have been made in the office at Walkerville: William Woollyatt, general superintendent and traffic manager; A. Leslie, accountant and auditor; J. H. Coburn, solicitor; Owen MacKay, engineer; S. Austin, mechanical superintendent; H. Morris, road master.

The Sooysmith Co. finished pier No. 8, the last of their work in connection with the Cornwall bridges of the O. & N. Y. Railway, last month. In less than seven months' work time ten piers, averaging about 1,000 yards of masonry in each, and four concrete abutments have been built, and with the single exception of the killing of Johnston by the falling of a tower, not the slightest casualty has occurred, nor a man been sent to the hospital.

W. T. Jennings, C. E., engineer of the James Bay Railway Commission, has returned to Toronto after making a preliminary survey of the Temegami & Wahnapitae districts to the Height of Land, having made a canoe journey of 700 miles. Mr. Jennings sent Mr. Sankey on to James' Bay to examine the bar at the mouth of the Moose River, and to report on the possibilities of constructing harbors on the south shore of James' Bay. Mr. Sankey is expected back as we go to press, and Mr. Jennings' report will be awaited with interest.

An important railway deal was closed Aug. 20th, when the Toronto General Trusts Company, representing the estate of the late John Leys and other trust interests in their keeping, negotiated the sale of the Port Arthur, Duluth & Western Railway to Mackenzie, Mann & Co., for a price said to be in the neighborhood of a quarter of a million. It is understood that it is the intention of Mackenzie & Mann to extend the

road forty or fifty miles into Minnesota to connect with the railway systems of the Northwestern States. It is also intended to connect it with the Rainy River Railway, a charter for which Mackenzie & Mann have secured and on the construction of which they are now working.

Mining Matters.

A 30-barrel oil well has been struck on the farm of F. W. Smith, Dunwich, Ont.

It is said that a valuable deposit of copper has been discovered at Wickham, Que.

A placer strike has been made on Rover creek, near Nelson, B. C., and many claims are being staked out.

The Libbey mine, Brookfield, N. S., cleaned up in July over 350 ounces of gold aside from the concentrates.

There is a report that gold in paying quantities has been found near Pinmaukin, on the head waters of the Rivers Shipshaw and Bersiamites, Labrador.

A natural gas well has been struck on the farm of Jacob Smith, near Ryckman's Corners, Ont. James Marshall, Barton, Ont., is the owner of the well.

The Nova Scotia Steel Co. has an order for 70,000 tons of iron ore from a German smelting company. The ore will be shipped from the Belle Isle mine.

Very rich mica has been discovered in the neighborhood of Kazabazua, Ottawa county, Que. The mine is turning out mica large enough, it is said, to cut 14x22 inches.

It is reported that a seam of anthracite coal has been located at Macadam's Lake, about 15 miles from Sydney, C. B. Dr. Gilpin gives an opinion that is favorable to the find.

The Trail Smelter, Trail, B. C., is increasing its boiler plant and has placed an order with James D. Sword, representing the James Cooper Mfg. Co., Ltd., Montreal, for another 80-h.p. boiler, to be added to the present battery.

The Hall mines, Ltd., Nelson, B. C., is re-equipping its tramway line with a complete new set of buckets, and has placed the order with James D. Sword, of the James Cooper Mfg. Co., Ltd., for 810 buckets. Delivery is to be made within eight weeks.

The James Cooper Mfg. Co., Ltd., is now erecting for the Whitewater Deeps Mining Co., Whitewater, B. C., complete 10-drill Ingersoll-Sergeant air compressor plant of the belt driven type, and installing Pelton water wheels with half a mile of converse lock-joint pipe and a mile of air line pipe.

It is said that the United States prospectors who are boring for oil at Lake Ainslie, C. B., have reached a depth of 1,600 feet, and were compelled to desist for want of further appliances to work at that depth. It is reported that the indications continue to be favorable and numerous as to the presence of petroleum in this neighborhood.

The Council of the Canadian Mining Institute has decided to hold the next meeting of the members at Nelson, B.C., early in October. Although it is yet too early to indicate a programme, we understand that already a number of papers have been promised, among the writers being: W. Blakemore, Crow's Nest Coal Co., Coal Creek; Wm. Braden, M.E., Pilot Bay; J. G. Gwillim, M. E., Sloean City; H. Percy Leake, M.E., Revelstoke; J. L. Parker, Rossland; O. E. S. Whiteside, M.E., Anthracite; H. A. Guess, Keewatin, Ont.

The Bannockburn, Hastings County, Ont., mine has just placed an order with the James Cooper Mfg. Co., Ltd., for a 30-horse power Lidgerwood hoisting engine with necessary boiler, pump, etc. This firm's erecting engineer has just returned to Montreal after completing the installation of a plant for the Regina Canada Gold mines, Ltd., Rat Portage, Ont. This consists of a 15-drill cross compound condensing Ingersoll-Sergeant air compressor, battery of boilers, ten drills, etc. Secretan & O'Boyle, Rat Portage, Ont., have increased their plant by ordering through the James Cooper Mfg. Co.'s Ltd., agent at that point, Ingersoll-Sergeant drills.

The Chatham Oil Company are boring three new wells at Thamesville, Ont. The large well struck by this company some time ago is still pumping fifty barrels per day.

The Noble Five Mining Co., Sandon, B. C., has just installed a new 7-drill compressor plant supplied by the James Cooper Mfg. Co., Ltd., Montreal, together with 1½ miles of pipe line and necessary accessories for the plant.

The Dufferin mine, Salmon River, N. S., plant is now running at its full capacity. It consists of an Ingersoll-Sergeant 15-drill cross compound condensing compressor, one 40-horse power and one 50-horse power Lidgerwood double drum double cylinder hoisting engine, battery of boilers, complete complement of drills, mountings, etc., all supplied by the James Cooper Manufacturing Co., Ltd., Montreal. This enterprising firm has received an order from the North Brookfield, N. S. Mining Co., for two more hoisting engines, one to increase the present plant, and one for new property that is being opened up. The Broad Cove Coal Co., of Broad Cove, C. B., has just installed an Ingersoll-Sergeant piston inlet air compressor, and complete coal cutting plant purchased through the Halifax office of the James Cooper Mfg. Co., Ltd.

The Rossland, B. C. branch office of the James Cooper Mfg. Co., Ltd., reports that its erecting engineer has returned from Anaconda, B. C., where he has been erecting a 12-drill compressor plant for the British Columbia Copper Co. The Athelstan Gold Mining Co., Rossland, B. C., has placed an order with J. D. Sword, representing the James Cooper Mfg. Co., Ltd., for preliminary plant, consisting of hoisting engine, boiler, pump, etc. The Liberty Mining Co., with headquarters at Rossland, B. C., has installed an Ingersoll-Sergeant piston inlet compressor with full complement of drills, etc., having purchased this through the Rossland branch of the James Cooper Mfg. Co., Ltd. The B. A. Corporation, Rossland, B. C., reports that it has both compressors that were installed by the James Cooper Mfg. Co., Ltd., of 12-drill and 5-drill capacity respectively, now running, and development work will be proceeded with with great vigor. This company in the Great Western Nickel Plate, West Le Roi and Josie is operating 19 Ingersoll-Sergeant drills.

The Messrs. McGregor's attempt to work their property at Fifteen Mile Stream, N. S., open cast or quarry fashion, has had to be abandoned. The quartz which it was expected to strike was not met with, and that crushed bore so little gold that it would be a loss to work. This is a disappointment after the very heavy outlay of late. So complete are the arrangements at this mine, and so excellent the machinery, that quartz in larger leads yielding a dollar's worth of gold to the ton can be worked to advantage. But we are glad to learn that the disappointment of the owners soon gave place to satisfaction. A shaft was planned to be sunk a depth of a hundred and fifty feet, at a distance of fifty feet or so from the open cast. At that depth paying quartz was expected to be met with. The shaft, however, had not gone twenty feet when it was found the large lead showed gold all round. Besides the quartz from this shaft other quartz will be mined from what is known as the 'Orient' mine, which after being idle for a long time has been pumped out. From these two shafts it is expected sufficient material will be obtained to keep the fifty stamps fully employed. The cable road built for the open cast can be utilized in taking one from the new shaft.

Electric Flashes.

A company of American capitalists talk of utilizing the water power of the Jacques Cartier river for electrical purposes.

The promoters state that the necessary capital has all been subscribed for the power development at Fenelon Falls, Ont.

The Electric Co. of Windsor, N.S., has ordered a 100 horse power, Robb-Armstrong engine from the Robb Engineering Co.

Carmen O'Dell, of Annapolis, N. S., is increasing his electric lighting plant by the addition of a 50 k.w. "S.K.C." Generator.

The Benallack Litho. & Printing Co., Montreal, has ordered from the Canadian General Electric Company, one of its latest type motors.

The Nelson, B. C., Electric Light Co. has sold out to the municipality for $35,400.

The Metropolitan Railway Company, Toronto, is now extending its line to Newmarket, Ont., which it is expected to reach by Nov. 1st.

The Hamilton smelting works will be fitted out with electric lights soon. The company will put in ten arc, and fifty incandescent lights.

The Canadian General Electric Co. has received an order from the corporation of New Westminster, B.C., for one of their 150 kilowatt monocyclic alternators.

The Hamilton Cotton Co., Hamilton, Ont., has decided to light its mills with electricity, and has placed an order with the Canadian General Electric Company for one of their 40-k.w. direct connected generators.

The West Kootenay Power & Light Company, Rossland, B.C., is rapidly extending its business, and for a recent extension has ordered from the Canadian General Electric Company three large feeder panels and two transformer panels.

The British Columbia Electric Railway Company of Vancouver, B. C., has found it necessary to increase its arc lighting plant, and has placed an order with the Canadian General Electric Company, for 1-125 light multiple brush arc dynamo.

R. H. Smith, Tilbury, Ont., whose plant was recently destroyed by fire, has placed an order with the Canadian General Electric Co., for an entirely new plant, consisting of two 15-k.w. standard Edison D. C. dynamos, and one 30-light arc machine. He expects to be running again in about two weeks.

The Kingston, Ont., Electrical Society has organized with these officers: C. Livingston, president; A. Chadwick, 1st vice-president; R. J. Dunlop, 2nd vice-president; R. H. Fair, Thomas Mills, D. E. Starr, John Carson, Joshua Knight, M. D. Curtis, G. McLean and Shibley, directors; Thomas Mills, treasurer, and J. P. Oram, secretary.

The Union Carbide Company, of Chicago, is arranging to greatly enlarge its plant at Sault Ste. Marie for the production of calcium carbide. The plant at Niagara Falls will be continued, but that at Appleton, Wis., will it is said, be discontinued. Twenty dynamos will be used in the new plant, and they have been purchased. These machines are single-phase, low-frequency alternators of 500 kilowatts each, delivering 2,500 amperes at 200 volts.

Herbert Webster, formerly of the firm of Webster and Hicks, Norwich, Ont., has secured a franchise for furnishing the town with electric light. The Canadian General Electric Company is supplying the entire electric equipment, which consists of a 700 light single phase alternator; marble panel switchboard, transformers, wiring. The corporation has contracted with Mr. Webster for the lighting of the streets by 40-32 c.p. incandescent lamps, operated in series.

The Montreal Cotton Co., of Valleyfield, P. Q., has placed a large increase order with the Canadian General Electric Company for induction motors, consisting of two 50-h.p., one 75-h.p., five 100-h.p. and one 200-h.p. When these are completed the cotton company will have one of the largest isolated electric power plants in America, the Canadian General Electric Company having already installed for this company, in generators and motors, a total of between 3,000 and 4,000 h.p.

The Canadian General Company has just closed a contract with the Lunenburg Gas Company, of Mahone Bay, N. S., for a 100 kilowatt three phase revolving field type alternating generator. This installation is to be used for the transmission of electric current, from a water power, situated about 9 miles from the town of Lunenburg, and will be operated without transformers at a potential of 4,000 volts. The company have also received an order for the wire to be used in the erection of the transmission line.

The amalgamation of the District Railway and Q. M. & C. Railway Companies is to be followed shortly, we understand, by the absorption into the joint concern of the Montmorency Electric Power Company. The shareholders of the Q. M. & C. Electric Railway Company will meet on the 13th inst. to ratify the bargain, and those of the Montmorency Electric Company a few days later. The trains of the Q. M. & C. will be run by electricity next year, and there will probably be an electric line along the Beauport road as far as Montmorency Falls.

L. E. Whitehead has resigned his position as superintendent of the Sherbrooke Street Railway.

The Peterboro Electric Light Co. is about to erect a modern power house at a cost of about $35,000.

The ratepayers of Barrie, Ont., have carried a by-law to raise $35,000 to build a municipal electric lighting plant.

An electric light system, arc and incandescent lights, has been installed by the C. P. R. at McAdam Junction, N. B.

Percy Domville has accepted the position of electrical expert for the city of Hamilton, Ont., in connection with the municipal lighting project.

A contract has been signed by the Canadian Niagara Power Company to supply light, heat and power to the Hospice of the Carmelite Fathers at Falls View.

A rumor is current that the Ottawa Street Railway Company has bought the Ottawa and Gatineau Valley Railway, and will convert it into an electric road.

As the people of Perth, Ont., defeated the Lanark County Electric Railway bonus by-law, there is now a scheme on hand to connect Lanark with Carleton Place.

S. C. Drummond, representing the British Electric Traction Co., of London, Eng., has applied to the Nelson, B. C., town council for a charter for an electric street railway.

There is talk of connecting the Niagara Central Railway with an electric road and extending it from St. Catharines to Port Dalhousie, Ont., and perhaps Beamsville, Ont.

L. E. Whitehead has resigned his position as superintendent of the Sherbrooke Street Railway. R. R. Smith, recently of Worcester, Mass., will assume the duties of superintendent.

A generator at the London, Ont., Electric Company's power house was burned out by the storm, Aug. 16th, and as a result power could not be supplied to a number of factories for a short time.

The ratepayers of Campbellford, Ont., have voted a by-law to raise $8,000 for the construction of a new incandescent light system over the entire village, to replace the one in use at present.

The Fisher Equipment Company of Chicago, manufactures electrically driven auto-cars, of which one known as a coach delivery wagon is now the property of the Robert Simpson Co., Toronto.

The Rat Portage Lumber Co. has fitted a motor to the car which supplies the planing mill and sash and door factory with lumber from the yards, and now has the first electric railway in Rat Portage, Ont.

The Jacques Cartier Pulp and Paper mill, Point Rouge, Que., has arranged to light the new pulp and paper mills by electricity. The order for the plant has been placed with the Royal Electric Co. and is to be installed immediately.

The Shawenegan Water and Power Company has advanced sufficiently with its plans for the installation of a plant capable of developing 100,000-h.p. to be enabled to call for tenders for the construction of the headrace, excavation for the wheel pits, etc.

The municipal ownership idea has apparently not swept Hamilton. A proposal to purchase the street railway has been rejected by the ratepayers by a vote of 264 to 2,043. Hamilton has at present an arrangement with its street railway that yields the city $16,000 a year. This coupled with the fact that only part of the voters were allowed to vote may account for the result.

A meeting of the shareholders of the Eastern Townships Light, Power and Carbide Co., was held at North Hatley, Que., a short time ago. The new company has been formed for supplying the electric light system to the villages of Waterville, Compton, Eustis, and North Hatley, and also to manufacture calcium carbide. The capital stock of the company is $50,000. At a subsequent meeting of the directors the following officers were elected: President, J. A. Gordon, North Hatley; vice-president, N. N. Walley, Sherbrooke; general manager, Dr. C. J. Edgar, Sherbrooke; secretary-treasurer, O. Roy, Montreal; assistant secretary-treasurer, Joseph Goodwin, North Hatley; solicitor, Mr. M. F. Hackett. The company has purchased the electric plant formerly owned by Edgar & Roy, and propose extending the business.

A charter for a railway to be operated by steam or electricity from Sault Ste. Marie to Michipicoten has been applied for.

The Stevens Mnfg. Co., London, Ont., has closed the electrical department of its business and will confine itself in future to agricultural machinery, etc.

The Royal Electric Co. is installing in the sub-station of the Cataract Power Co., on Victoria street, Hamilton, a 30-h.p. S. K. C. induction motor, which is to be used in driving the fans for the air blast transformers.

Electric light and gas fixtures are beautifully illustrated in catalogue No. 20 issued by Munderloh & Co., Montreal, wholesale electrical supplies and dealers in incandescent and arc light plants and electrical goods generally.

The Waterous Engine Works Co., Ltd., Brantford, Ont., is adding to its shop capacity, and requiring more power, is installing a 30-h.p. induction motor from the Royal Electric Co., which is to be operated from the alternating current lines of the Brantford Electric & Operating Co. This makes over a 100-h.p. in S. K. C. motors now operating in Brantford.

The Windsor Electric Light & Power Co., Windsor, N. S., is enlarging the recently installed electric lighting plant. It is adding one 100-k.w. and one 40-k.w. S. K. C. generator, with an additional complement of transformers and material. The S. K. C. apparatus and transformers are from the Royal Electric Co.

J. T. Ayers, of Lachute, has secured a franchise from that town to furnish incandescent electric lights. For this purpose he has placed his order with the Royal Electric Co., for a 100-k.w. S. K. C. generator, and the necessary transformers and material for the construction of the entire plant. The new plant will be driven by a water power situated about two miles from the center of the town.

The Ontario Telephone and Switchboard Construction Company, Ltd., has received an Ontario charter to manufacture telephones and other electrical appliances; capital $75,000. The incorporators are: R. Fox, T. H. Smallman, F. B. Leys, T. H. Purdom, R. A. Bayly, J. Labatt, M. Masuret, J. Milne, J. D. Wilson, M.D., and J. R. Minhinnick, London, Ont.; and R. H. Evans, H. C. Walters, Detroit, U. S.

The fourth of the 2,200-k.w. S. K. C. generators was set up in the Chambly Electric Manufacturing Co.'s power house at Richelieu, Que., a few days ago, and there are now ready for operation over 10,000-h.p. These are the largest electrical motors ever built in Canada, and the largest excepting Niagara Falls, that has ever been built. Electricity is no longer in its infancy, neither is Canada behind in the development of the science.

The Dundas Electric Light Co. has received a franchise from the town of Dundas, Ont., to furnish incandescent lights throughout the town, and also a contract for the street lighting. Both systems must be in operation by the first of November, 1898. The entire electrical equipment, consisting of a 50-k.w. S. K. C. two-phase generator, with 500 lights capacity in transformers, and all the necessary wire and material, is to be supplied by the Royal Electric Co., and the plant is to be installed at once. Geo. H. Harper, Dundas, will be manager of the new company.

Friday, the 26th August, 1898, will be memorable in the annals of electricity in Canada, being the day on which the Cataract Power Co., Hamilton, Ont., turned the first current on to the long distance transmission line between Decew Falls and Hamilton. The water was let into the fore bays and pipe line at about 3 p. m., and at 3.30 p. m. the hydraulic plant, consisting of two 1,500-h.p. waterwheels, and the electrical plant of two 1,000-k.w. S. K. C. generators, were turned over, the switch closed and the power sent to Hamilton, a distance of 35 miles, where it was utilized for lighting arc and incandescent lamps, and also for driving a 40-h. p. S. K. C. induction motor. The incandescent lamps in the sub-station, in Hamilton, were very artistically arranged in the form of a large star and maple leaf, and were kept lighted until far into the night. The plant will be started up permanently in a few days.

At the Royal Electric Company's fourteenth annual meeting the reports presented were considered to be satisfactory. The gross revenue was shown to have been $955,826; expenditure $636,057; interest and fixed charges, $42,609; net profit, $277,160. Four quarterly dividends have been declared, of two per cent each, equalling $120,000. Ninety thousand dollars was charged to profit and loss for reduction of assets in patents; $25,000 for depreciation of plant, and $31,992 for other reasons. It was shown that the company last year made eighteen and one-half per cent. on invested capital, as compared with sixteen and one-half per cent the preceding year. A dividend of eight per cent has been paid yearly since 1891. The company now employs 600 hands, and its wage bill exceeds a thousand dollars a day. There was expended in material last year $400,000. Business in new customers has increased fourteen per cent., and for lights, sixteen per cent. The addition of a new plant has resulted in an economy of coal consumption of 5,300 tons of coal; as compared with the figures of two years ago. The old board of directors were re-elected, namely: The Hon. J. R. Thibaudeau, president; D. Morrice, vice-president; F. L. Beique, Allan R. Macdonell, H. S. Holt, J. A. L. Strathy, A. Brunet, Edwin Hanson, Robert Cowans and W. H. Browne, general manager.

Personal

James Quigley, Kingston, has been appointed chief engineer of the Deaf and Dumb Institute, Belleville, Ont.

George Bottomly, aged 25, was killed recently by an emory wheel bursting in his father's mill, Halifax.

John White, for nearly a quarter of a century foreman in MacGregor, Gourlay Company's foundry, died in Galt, Ont., a short time ago.

James D. Banks, Toronto, formerly engineer on the steamer Ada Alice, committed suicide a short time ago by inhaling gas, and thus causing asphyxiation.

Louis Simpson, Belleville, Ont., an engineer on the Grand Trunk, was struck by the pilot engine in the Brockville yard, August 2nd, and instantly killed.

C. W. Taylor, vice-president and general manager of the Canada Carriage Co., Brockville, died last month, much to the regret of a large circle of friends.

F. R. F. Brown, late mechanical superintendent of the I. C. R., is said to have fallen heir to $50,000 through the death of a relative in England.

George Kelly was caught in a belt in the George Gillies Company belt factory at Gananoque, Ont., and was thrown over the shaft and instantly killed.

Dan. McAnnany, contractor, of St. Boniface, Manitoba, is dead from the result of an accident on the Crow's Nest railway construction, where he had a contract.

Frank Travers, a steam-fitter, was accidentally killed a short time ago at the Mimico asylum, while engaged in repairing the heating apparatus. A radiator fell upon him.

A. P. Coleman, geologist for the Ontario Government, has gone to England to attend the British association at Bristol. He will read a paper upon the inter-glacial period.

Hector McLean, president of the International Brick and Tile Company, died at Bridgetown, N.S., a short time ago. He was one of the best known men in Annapolis county.

W. Griffith, engineer at the electric light station, Carleton Place, Ont., has resigned his position to go firing on the Parry Sound Railway. J. Bennett succeeds Mr. Griffith, and Geo. Fife takes Mr. Bennett's place.

William Madden, Westville, N. S., who has held the position of deputy inspector of mines in Nova Scotia for many years, has been appointed, by the Dominion Government, one of the mining inspectors in the Yukon.

A. H. Harris, the late traffic manager of the Intercolonial Railway, has been appointed general traffic agent of the Fitchburg Railway Company, in charge of all traffic affairs in the Dominion, with headquarters at Montreal.

Percy Girouard, son of Hon. Mr. Justice Girouard, of the Supreme Court of Canada, has been appointed chief in the Egyptian railway system at a yearly salary of £2,000 sterling, by the Imperial Government.

James Hutcheon, city engineer, Guelph, Ont., was up some 50 feet in the old rolling mills to superintend the fixing of a block and tackle to take down railroad rails, when he caught hold of a loose board and fell to the floor below, but fortunately escaped serious injuries.

George Coates, son of John Coates, president of the Ottawa Gas Co., blew off his arm by the accidental discharge of a gun and died in a few hours. The accident happened at Shaganaga Lake, near Hunter's Island, Algoma. Mr. Coates was 21 years of age, and a student in the Kingston, Ont., School of Mines.

William Cooper, contractor of Clinton, Ont., fell about thirty feet from a scaffold on Aug. 17th, and died in about 20 minutes. Mr. Cooper was one of the best known men in the county of Huron and very highly respected. He leaves a widow and family, one of whom is John A. Cooper, editor of The Canadian Magazine and secretary of the Canadian Press Association.

Wm. Fraser, engine driver on the Springhill and Parrsboro Railway, was instantly killed at Springhill station, recently. He went under the locomotive to do some work and while under accidentally struck the brake with his hammer. The throttle of the engine had been left open, and the striking of the brake released the wheels of the engine, which gave a jump and went about eight feet along the track.

W. F. Robertson, the new provincial mineralogist of British Columbia, graduated in 1880 with honors in natural science from McGill. His first practical work was at the Capleton copper mines in Quebec province. He afterwards went to Pennsylvania as superintendent for the Chemical Copper Company, and next assistant in New Jersey to H. M. Howe at the Orford Copper Company. Mr. Robertson after this became superintendent to James Douglas' copper works at Phoenixville, Pennsylvania, and after some time there went back to the Orford Copper Company as engineer and put up their large works for that company, which, it may be mentioned, smelts the Sudbury nickel ore. Mr. Robertson later on was engaged as engineer of the Spring Hill collieries in Nova Scotia. He then went to Spain in the employ of the Minas Sotiel Coronada, and after returning to this continent put up a large smelter for the Osceola Smelting Company in the Lake Superior district, and had also charge of the smelting works at Great Falls for the B. & M. Co. Having gone back to the Orford Company as superintendent, he finally settled down in New York in private practice as a consulting mining engineer and has given reports on mines in various parts of the continent.

FIRE-PROOF BUILDINGS.

BY FRANCIS C. MOORE.

(Continued from last issue).

All buildings over 125 feet high should be provided with 4 inch, or, better still, 6 inch vertical pipes, with Siamese connections at the street, for the use of the fire department, extending to the roof, with hydrants at each story and on the roof. This would save the time of carrying hose to upper floors—a difficult task in the case of high buildings. Ample tanks of water should be provided on the roof, supported by protected iron beams resting on iron templates on the brick walls, to supply the building's inside pipe system for fire extinction, and secure pressure by gravity or by some other method constantly operative, especially on holidays and at night. Stone templates should not be used, and care should be taken to secure strong supports, so that, in the event of fire below, the tanks will not come crashing through the building to destroy it and endanger the lives of firemen. Two such disasters in "fire-proof" buildings within a year show how true is this proposition. Tanks in the basement, under air pressure are also a great advantage, and recent invention has perfected them to the point of reliability. Fire Marshal Swenie, of Chicago, urges that standpipes should not be less than 6 inches internal diameter, and that a check valve should be provided, so that when steamers are attached, their force will be added to that of the local pumps. Each floor should have hose connections with the standpipes, and sufficient hose to reach to the most remote point of the floor above, and this hose should be frequently inspected to see that it is in order. He recommends that a code of signals, by which communication can be established between the firemen and the engineer of the building, is essential.

All high buildings should have constantly present, night and day, some competent person understanding the elevator machinery, fire appliances, etc., so as to aid the firemen in reaching the upper levels; and there should be sufficient steam in the boilers, at all times, to run one elevator.

Marble, slate, and other stones are certain to disintegrate or crumble when subjected to the joint action of heat and water. For this reason 90 per cent. of the staircases in modern "fire-proof" buildings would be found utterly unreliable in the event of fire, either for the escape of the inmates or for the use of firemen—a serious consideration. Stone treads are usually let into iron rabbet frames, and as these stone treads would give way in case of fire, it would be impossible for a person to find a footing on the stairways; 2 inch oak treads might actually last longer; but a safer staircase would be one the framework of which is of iron, the tread having an iron web or gridiron pattern, the interstices or openings of which should be small enough to prevent the passage of a foot, underlying the stone or slate, so that if the stone tread should disintegrate, the staircase still remains passable. It is possible to have the supporting tread of open work cast iron in an ornamental pattern, which, in relief against the white marble tread resting on it, would present a tasteful appearance from the underside or soffit of the staircase, with this great advantage, that in the event the action of fire and water should pulverize the marble or slate tread, it would still afford a safe support for the foot. It is generally supposed that it is not necessary to be careful as to stone treads in buildings occupied solely for offices separated in "fire-proof" hallways in which, it is claimed, there is nothing to burn; but in the case of one large "fire-proof" building of this kind in New York, I found the space under the staircase in the basement story was used to store the waste paper rubbish of the building—material particularly likely to cause a fire by concealed matches, oily waste, cigar or cigarette stumps, etc., and to make a lively and quick fire, quite sufficient to destroy stone staircase treads. Even where there is no combustible material in the hallway, if the staircase is near windows, stone treads may be destroyed by exposure to burning buildings and by the combustion of window frames, dadoes, and other wooden trim.

No building should exceed in height the width of the street on which it is located, from the view point of light and health; nor, in any case, in excess of 95 feet for mercantile occupancy, nor a height in excess of 200 feet for office occupancy.

It should be remembered that merchandise, furniture, etc., are combustible, no matter whether located in "fire-proof" buildings or in ordinary buildings. This obvious fact seems generally to be ignored. In fact, combustible material will sometimes be more effectually and thoroughly destroyed in a "fire-proof" building than in an ordinary building, since the early collapse of the latter may smother the fire and effect salvage, whereas "fire-proof" floors support the contents of the former, and distribute them so that they are more certain to be destroyed.

Enclosing walls should be of brick, the brickwork of the lower stories especially, if not of all, being laid in cement mortar. In fact, the specifications for a building in the compact part of the mercantile section of a city, ought to be drawn in contemplation of the possible cremation of its contents, and the generation of heat considerably greater than 2,000 degs. Fahr. The heat of a wood fire is from 800 to 1,140 degs.; charcoal, about 2,200 degs.; coal, about 2,400 degs. Cast iron will melt at between 1,900 and 2,800 degs.; wrought iron, 3,000 to 3,500 degs.; steel, 2,400 to 2,600 degs.; and if an architect should be required to draw specifications for a building adjoining others, with the knowledge beforehand that its entire contents, from cellar to roof, were to be totally consumed, and he were under a bond to pay damages to surrounding property, he would not be more severe in his exactions than should a building law protecting neighborhood rights in the enjoyment of property; for a mercantile or manufacturing building sometimes generates a greater heat in combustion than a smelting furnace. It is hardly necesary to deal with the foundations of buildings. The question is an engineering problem which hardly requires suggestions from a fire standpoint, and I shall not deal with it here, other than to touch again upon the im-

portant point of not having wrought-iron or steel columns in the cellar or basement, where moisture and gas conditions would increase the danger of rust. These, as already stated, should be of brick, the lower stories laid in cement mortar, not less than 16 inches thick at the top of the building and increasing 4 inches in thickness for every 25 feet in height to the bottom. This would require a 44 inch wall at the grade for a 200 foot building. The thicknesses here recommended are for buildings not exceeding 100 feet in depth. If they exceed this depth without curtain or cross walls, or proper piers or buttresses, the walls should be increased in thickness 4 inches for every additional 100 feet in length.

Brick is the best known resistant of fire. Stone yields readily to the combined effect of heat and water, and even terra-cotta or burned clay tile cannot be regarded as a perfect substitute for hard-burned brick. Under no circumstances should the iron framework of a skeleton building be incorporated in thin enclosing walls. No wall that has not a cross section sufficient to support itself without the ironwork should be allowed, aside from the importance of having it thick enough to prevent the passage of hot air from an adjoining building. Curtain walls for enclosing walls supported by the longitudinal members of skeleton construction are objectionable; they are liable to be buckled out by the expansion of the framework. The great trouble with modern "fire-proof" structures is, that while the separating "fire-proof" floors tend to prevent the passage of flame from one story to another, the enclosing walls are often insufficient to prevent heat from igniting the contents of an adjoining building, so that what is gained by preventing the spread of fire vertically is lost laterally. It should be borne in mind that the thickness of walls herein recommended is not for carrying capacity as bearing walls. Thinner walls would answer for that purpose. It is intended to confine the heat generated by a fire, and should be required in the compact portions of cities, where every man should be compelled to build with reference to the safety of his neighbor.

Architects and builders generally seem to have in mind only the carrying capacity of walls, and to lose sight of this important fact. As the contents of a mercantile building and its floors burn, they sink to the bottom, where enormously high temperatures are reached, and it is for this reason recommended that walls should increase in thickness as they approach the bottom, on the same principle that the walls of smelting furnaces are thicker at the bottom than at the top. It is the generally accepted opinion that a 12 inch brick wall will prevent the passage of fire, but a much thicker wall will fail to confine the heat of a burning building on the first floor particularly, sufficiently to prevent the ignition of combustible merchandise or other material in an adjoining building. In a fire which occurred in Boston, several years ago, combustible material was ignited through a 3 foot wall, which became so hot as to thus conduct the heat into the adjoining building.

I do not believe "skeleton construction" so-called should be permitted for stores, warehouses, or manufactories in cities, as the walls are not thick enough to confine the heat of burning merchandise. In some of our Western cities, Detroit, Chicago, etc., the practice is growing of using hollow tiling, bonded like ordinary brickwork, 12 inches thick, for enclosing walls, instead of brick, the exposed steel frame being protected by terra-cotta slabs about an inch thick. The Leonard building, in Detroit, destroyed by fire October 7, 1897, was an example of the great danger of this style of construction. It was ten stories high, and as fast as the columns or wall girders were warped by the heat the tiling dropped out like loose bricks, leaving the entire structure after the fire a ragged cage-work of iron with very little of the tiling on the enclosing walls and none of the floors intact. The contents were, of course, totally destroyed.

Bond stones should not be allowed in piers, especially in the cellar or basement, or in piers vital to the building or carrying great weights. Stone yields readily and quickly to the combined effects of water and heat and, disintegrating at its edges, gradually releases the bricks above it, so as in time to destroy the integrity of the pier. Bond stones are employed by the mason to steady his work. A green brick pier while being laid is frequently unsteady, and a bond stone enables him to progress with his work by steadying all below it so as to receive new courses of brick. In all cases the bond should be a cast-iron plate. If the plate should be cast with holes through it about 1½ inches in diameter, so that the mortar and cement can thoroughly incorporate the plate with the masonry above and below, it would be an improvement. Wrought iron is liable to rust and should not be used. Where bond stones are used in the outer walls of buildings they are less objectionable, but for inside piers they are so dangerous that they ought to be prohibited by law. It not infrequently happens that a building of otherwise admirable construction has its weakest point in the cellar, where a stone pillar forms the basis of support of the entire line of columns through the building. In case of fire and the application of water these stone pillars, no matter how substantial, whether single monoliths or stone blocks, will rapidly disintegrate and bring down the entire structure; and inspectors should carefully examine, especially in the cellars, for such construction. After the great Boston fire, granite piers were shovelled up and carted away like so much sand. It is quite a common practice, but a most dangerous one, to employ single stone columns, often of polished granite, to support the centre of a long stone lintel carrying the wall over the ornamental entrance of a building. Such a column would surely yield to the effect of fire and water and perhaps let down the entire front. The vertical supports, columns, pillars, etc., as already stated, should be of cast iron, cylindrical in form, of liberal thickness, especially in the lower stories, thoroughly tested as to sand holes, thin places, etc. Cast iron columns should be round, and not square. In the former shape there is less likelihood of defects in casting, sand holes, etc, resulting in uniform sound thickness of the shell. The columns should be planed to smooth bearings, so that the entire system of columns, from the foundation to the roof, may be securely bolted together and form a continuous line with joints for expansion and without any inequalities of bearings. Under no circumstances should wedges or "shims"* be allowed. This most important matter is often neglected. The flanges and corbel brackets for supporting beams should be cast in one piece with the column and not depend upon rivets or bolts. Rivets, aside from the danger of shearing strains, are almost certain to rust to the point of danger. The beams should be riveted or bolted to lugs on the columns, however, as a tie between the side walls, holding the entire structure firmly and consistently together as one rigid whole and yet with play for expansion. Col. George B. Post, of New York, has devised a form of cast-iron cage construction consisting of pillars and floor beams, the members of which lock into each other without the use of bolts or rivets, forming a very rigid construction, and saving the cost of mechanics for bolt and rivet work.

(Continued in next issue)

—Gaseous fuel as a substitute for the direct consumption of coal continues to extend in England, state Matheson & Grant in a recent circular to the engineering trades. Not only are the waste gases of blast furnaces being more skilfully utilized than heretofore, but improvements and economies in the making of producer-gas from cheap waste coal at the collieries, encourages its use as power for gas engines, and in some cases as fuel for steam boilers. This change, if it continues to extend, will go far to solve the question of smoke prevention in iron manufacturing towns.

*Shims are pieces of slate or iron inserted to secure a true vertical, where the two surfaces have not been properly levelled or planed.

SPLENDID WATER POWER

and special inducements to Manufacturers to locate on the

St. Maurice River,

PROVINCE OF QUEBEC.

The Shawinigan Water and Power Company is prepared to treat with parties desiring to lease large units of power. For information address the Company,

PURIFICATION OF SEWAGE BY IRRIGATION.

BY W. M. WATSON.

There is a good deal of misconception with reference to sewage purification by irrigation. It appears natural to convey all filth and manure to the land from whence it came, and make the cycle of production and consumption complete, and probably on this ground the many scientists and public officials favor irrigation. But experience and discovery have shown that land can only act as a filter, that is, a place for the lodgment of micro-organisms, that live and do the work of cleaning the dirt from the sewage, thus bringing the fluid back to its former state of purity. To enable the microbes to do this, that able scientist, W. E. Adeney, proves that air must be supplied and properly distributed to every separate atom of sewage in the proportion of three parts of air to one of sewage. Air cannot possibly be distributed into all the particles of the soil of a farm or any other land to a greater depth than about one foot, and often less, and when sodden with water or snow very little if any atmosphere can penetrate. Many inventions are being tried to aerate even artificially made filters. The best yet known is to fill the filter quickly, allow it to stand for a given period, then slowly draw the fluid off. As the fluid settles from the filtrate air is drawn into the interstices between the small cubes the filter is filled with, in that way the micro-organisms secure sufficient oxygen to give them vitality. By another method porous pipes are placed among the small cubes of coal, coke, clinkers, or whatever material may be used to filter or separate the particles of sewage fluid and atmospheric air passed through them at a pressure of about four inches of water by a fan, so that a constant supply of air is conveyed to the interior of the filter and is distributed throughout during the time the sewage is passing through, and on that account the filters work continuously. It is obvious that land that cannot secure air except at the surface, therefore cannot form a lodgment for microbes that must have air to live. If there are no microbes then there is no purification, and a milk sieve would do just as good work as any land, or even any artificiai filter that cannot be supplied with air by some process or its equivalent (as some claim) of soda or similar chemicals. Arthur Turley, .C.E., inspector of English sewage disposal works, states on page 5 of his report for 1890, that where irrigation is adopted, either alone or in combination with some precipitating process, the foreign matter in solution in the sewage is frequently increased by salts washed out from the soil. German chemists have given much attention to this disadvantage attendant on land filtration. The Teltower Sea, a lake near Berlin, was fouled by the effluent from the noted Berlin sewage irrigation works. Professor Muller reports that during nearly six months of the year no vegetation takes place on the land, and in hard frosty weather the land will not act properly, and the sewage must be stored up in tanks. Dry earth exerts a strong purifying influence on fœcal matter, but has very little if any effect on the other ingredients contained in sewage which contain millions of dangerous bacteria. People go into ecstacies if they see a sewage irrigation land that appears to perform its work well, as they usually do for one year, and sometimes as much as four years, and the success is proclaimed far and wide.

It came to my knowledge that a sewage farm near Montreal was considered to be very near perfection, and on September 14th last I had the privilege of inspecting this farm at St. Lawrent College, St. Lawrent, a village near Montreal. The farm contained 1¼ acre or 6,000 square yards of land, raised by light soil to a level of over 20 inches above the natural ground line. The population served by this irrigation system was said to be 400 persons, the daily sewage was about 4,500 gallons, an average of 11¼ gallons per head, which would allow the very small amount of only three quarts of sewage to one square yard of land per day. This system cannot properly be called a sewage farm, it is really the land filtration system, because the soil is well underdrained by having a row of land tile pipes laid under the centre of each of the twelve bays or divisions which deliver the effluent after the sewage has passed through the land into the parish drain, this coupled with the fact that the land was raised with light porous soil makes it an artificial land filter. The surface appearance of the land is that of a checker board having twelve trenches cut across from the distributing channel to the opposite side and to cross trenches, each trench being about 15 inches deep. The irrigation land and necessary appliances were said to have cost $3,500, or an average of $8.75 per head of population. This is

exclusive of the sewage storage and collecting tank and the steam pump. This is a high price to pay for a system of sewage purification that can't possibly work efficiently during hard frosty weather, and that gives off a disagreeable and unhealthy odor each time the sewage is run onto the land.

The engine and pump send each day's collection onto the irrigation land in the space of about two hours, so that the land gets only two hours' work and 22 hours' rest and aeration daily, and it may also be observed that the small amount of only ¾ of a gallon of sewage to one square yard of land cannot make any serious effect on the light soil, and it will be quickly absorbed during the hot dry weather of summer. If it was possible for each town to secure a light porous land, well underdrained, and to allow their irrigation filters 22 hours' aeration each day, a bright, pure effluent would be the result for several years until the porous soil got fatty.

But not one town in ten can secure suitable land for sewage purification works, and if the land has to be properly prepared and underdrained so that it cannot possibly become waterlogged, then the cost is so high as to be prohibitive, because artificial tank filters can be built at about the same price that will do fifty times the amount of work, and work efficiently both summer and winter. It is next to impossible to efficiently aerate irrigation lands, and on that account they gradually become sick and clogged with injurious microbes, therefore, in time, they become utterly useless as did the irrigation system adopted at Berlin, Germany.

A week prior to inspecting St. Lawrent sewage works I was engaged to go to the Georgian Bay district and find out why a sewage works had become totally disabled and was discharging foul odors. This irrigation filter is very similar to the St. Lawrent one, but with more advantages, because it is built on high ground and can be clearly drained to a depth of over four feet.

The whole filter at the Georgian Bay was created by piling up gravel and sand inside of a wooden fence. It is only used in the four hottest months of the year, that is during the tourist season. The population using the irrigation filter when the place is full with guests is under 300, including servants. The size of this irrigation land is 80 by 45 feet, which is ample to purify the sewage discharged when the fact is taken into account that all the solid matter contained in the sewage is supposed to be extracted by settling tanks prior to to its being discharged over the irrigation filter, on the intermittent system of working 30 minutes and resting three hours, and at the rate of only 10 gallons per yard per day when working at the fullest capacity.

After working for only two months the pores of the filter got so clogged that no sewage would pass through it, the cause being that the sheet iron settling tanks were not large enough to give sufficient time for the solids to separate from the liquids and to prevent the manureal matter from passing over on to the irrigation filter, and when a filter becomes badly clogged or sick it is impossible to clean it except by putting the whole of the filtrate through a furnace, and bringing it to a red heat, or by turning it all over with a hand spade and spreading it out in thin layers exposed to the purifying influence of the air for a year.
